L-Phenylalanine, an amino acid with high rate of passage through the parenchymal capillaries when introduced through the carotid in the dog[9] or rat[10] was chosen to investigate the passage from the subarachnoid space to the blood. Figure 2 shows a typical curve of blood appearance of L-^{3}H-phenylalanine 'without carrier' (2 μM L-phenylalanine in the cup). The curve is similar to that of ^{3}HOH. When in the same animal the pia is removed and L-^{3}H-phenylalanine 'without carrier' was placed on the naked cortex, no significant radioactivity was detected in sagital sinus blood during the 8 min of the experiment. Results of the compartmental analysis of the L-^{3}H-phenylalanine experiments 'with pia' are given in Table 1. As for ^{3}HOH, a high correlation coefficient was found. The $t_{1/2}$ values for five experiments averaged 22 s and in a sixth experiment $t_{1/2}$ was 92 s.

The possible transport saturation of L-phenylalanine was tested comparing the rate of appearance of L-^{3}H-phenylalanine in sinus blood, when the cup contained ^{3}H-phenylalanine without carrier and 20 mM L-phenylalanine. These experiments are presented in Table 2. An inhibitory effect of about 50% is apparent, indicating that a mediated transport system is involved. A similar saturation phenomenon for disappearance of L-leucine from the subarachnoid fluid has been reported[11]. In dog 1, the L-^{3}H-phenylalanine passage in the first 60 s is higher for 20 mM L-phenylalanine than in the experiment 'without carrier'. In this animal, the 20 mM experiment was performed after the control, whereas the opposite order was used in dogs 2 and 3. It is possible that labelled L-phenylalanine incorporated in the brain after the first assay, exchanges (or counter-transports), with the cold L-phenylalanine of the second run, increasing the amount of label appearing in the sinus. From 120 s on, the inhibitory effect is evident.

Our results point to the participation of pial vessels in the transfer of substances from the subarachnoid CSF to blood. This transfer is selective for some substances, water, L-phenylalanine, and not for sodium for example. The transport is susceptible to saturation by the substrate in the case of the amino acid. These results are similar to the results of the experiments on dog brain where the molecules were introduced through the blood[7,9]. Sodium, like sucrose, remains in the vascular space in a single passage through the brain circulation, whereas water is extracted from the blood almost completely[7]. L-phenylalanine, L-leucine and other neutral amino acids cross the blood–brain barrier by a mediated transport mechanism[9]. We suggest that endothelial cells of both pial vessels and tissue capillaries can maintain the differential composition of the CSF and blood.

There are several references pointing to the permeability of pial vessels to different substances[12,13] and to their potential ability to form and to reabsorb CSF[14]. At least morphologically, the secretory conformation of choroid plexuses is not necessary for the formation of fluid. Perhaps their main function would be the active clearance of substances from CSF, the production and regulation of the fluid composition being reserved to endothelial cells of all the cerebral vasculature: pial vessels, parenchymal capillaries and choroidal capillaries.

TABLE 2 Influence of carrier L-phenylalanine (20 mM) on the passage of L-(^{3}H)phenylalanine from subarachnoid cup to blood

Dog	30 s	60 s	120 s	240 s	420 s
1	133	95	60	48	43
2	41	40	38	46	50
3	43	58	64	61	42

Three animals were used. The values listed are % control radioactivity calculated as blood-to-cup ratio in the 20 mM run divided by that in the run 'without carrier'. Both runs in the same animal. Times are intervals elapsed since the labelled solution was placed in the pial cup.

Replacement of acidic phospholipids by acidic glycolipids in *Pseudomonas diminuta*

PHOSPHOLIPIDS are characteristic components of the membranes of living cells, where in many cases they represent the major polar lipid components. The common phospholipids in Gram-negative bacteria are phosphatidylethanolamine, phosphatidylglycerol and diphosphatidylglycerol[1]. *Pseudomonas diminuta* NCTC 8545, however, contains high proportions of glycolipids and relatively low proportions of phospholipids when grown on solid media or in submerged culture[2]. The glycolipids are α-glucosyldiglyceride, α-glucuronosyldiglyceride and β-glucosyl (1→4)-α-glucuronosyldiglyceride[3], and the phospholipids are phosphatidylglycerol[3] and 6-phosphatidyl-α-glucosyldiglyceride[4]. It has been suggested that the acidic glycolipids (containing glucuronosyl residues) might behave as substitutes for acidic phospholipids in the membranes of this pseudomonad[5]. Here we describe studies on the lipid composition of *P. diminuta* grown in continuous culture in conditions of phosphate and magnesium limitation which support this suggestion. Moreover, in conditions of phosphate limitation the cells contain barely detectable amounts (0.3% of total polar lipids) of phospholipid, thereby suggesting that appreciable amounts of these compounds are not obligatory for the maintenance of membrane function.

Continuous cultures of *P. diminuta* were prepared aerobically at 30°C in a 600 ml chemostat constructed essentially as described by Baker[6]; the *p*H was automatically controlled at 7.0 ± 0.2 and a dilution rate of 0.2 h^{-1} was employed. Media were prepared using a standard mineral base[7] with the addition of cystine (50 mg/l) and 1 ml/l of a solution of vitamins (40 mg each of pantothenic acid, biotin and vitamin B_{12} in 100 ml) as recommended previously[8]; the carbon source was ammonium acetate (4 g/l). Phosphate-limited media contained KH_2PO_4 (25 mg/l) as the only phosphate-containing component and magnesium-limited media contained $MgSO_4$ (8 mg/l). Samples (250 ml) of steady state cultures were withdrawn from the chemostat vessel; the cells were collected by centrifugation, washed with NaCl (0.85%) and freeze dried.

Lipids were extracted from dry cells with chloroform-methanol (2:1, v/v) and the polar lipids examined by two-dimensional thin-layer chromatography followed by densitometry[9,10]. The proportions of the polar lipids obtained from representative cultures of phosphate- and magnesium-limited chemostat growths are shown in Table 1. The chemical nature of the individual lipids was indicated by their reaction with specific spray reagents for lipid phosphates[11] and α-glycols[12]; the identity of each lipid was confirmed by chromatographic isolation and analysis of the products of hydrolysis as described previously[3,4]. In addition to the expected polar lipids, a small amount of an unidentified component was detected; its staining properties on thin-layer chromatograms indicated that it was a glycolipid.

The amounts of phospholipids in the phosphate-limited culture were extremely small; only a trace (maximum 0.3%) of phosphatidylglycerol was detected and phosphatidylglucosyldiglyceride was absent. The lipids of the magnesium-limited culture contained significant proportions of phospholipids, the overall lipid composition being similar to that of batch cultures grown in a complex medium (Oxoid Nutrient Broth No. 2). The greatly reduced proportion of phospholipids in cells grown in phosphate limitation compared with those grown in magnesium limitation supports Wilkinson's suggestion that acidic glycolipids might have a similar function to acidic phospholipids in the membranes of some bacteria. This suggestion was also supported by the discovery[9] that in batches of *Bacillus cereus* T acidic phospholipids are partially replaced by an acidic glycolipid under certain growth conditions.

Table 1 Relative proportions of individual polar lipids in phosphate- and magnesium-limited chemostat cultures of *Pseudomonas diminuta* (expressed as % of the total polar lipid).

	Growth limitation	
	PO_4^{3-}	Mg^{2+}
Glucuronosyl diglyceride	33.0	27.0
Glucosylglucuronosyl diglyceride	24.0	21.0
Phosphatidylglycerol	0.3	22.0
Phosphatidylglucosyl diglyceride	—	7.0
Glucosyl diglyceride	40.3	18.0
Unknown glycolipid	2.4	5.0

P. diminuta is unusual in several respects; it can be distinguished clearly by DNA homology studies from other psuedomonads[13]. It has relatively smaller proportions of phosphates in its cell envelope and is remarkable in that it does not synthesise phosphatidylethanolamine, an almost universal component of the membranes of Gram-negative bacteria[1]. It is possible that glucosyldiglyceride may behave as a substitute for phosphatidylethanolamine in this organism as an interrelation between this phospholipid and diglucosyldiglyceride has been established in the lipids of Gram-positive bacilli[9,14,15]. Diphosphatidylglycerol is not synthesised by *P. diminuta*, *P. pavonacea* and *P. rubescens*[2]. In at least the first organism, phosphatidylglucosyldiglyceride might assume the function of diphosphatidylglycerol; both of these lipids contain four fatty acid residues and thus show a superficial structural similarity.

It is apparent, therefore, that the presence of phospholipids as major components of at least some biological membranes is not obligatory provided that other polar lipids, such as acidic glycolipids, are present. It is interesting that an acidic glycolipid, glucosyloxyoctadecenoic acid, has been found[16] to comprise a much higher proportion (6%) of the total lipids of *Aspergillus niger* than does the sum of all the phospholipids (2%).

These results suggest limited interchangeability between polar lipid types within substitution classes[17] which are essentially based on the overall charge of the lipids. Acidic phospholipids and acidic glycolipids form a major substitution group and zwitterionic phospholipids, ornithine amides[18] and neutral glycolipids form another.

We thank Dr S. G. Wilkinson for suggestions.

New approach to study of oxygen transport in plants using chemiluminescent method

THE possibility that roots are aerated by molecular oxygen transported from the shoots continues to attract attention. A number of methods have already been involved in the study of this phenomenon, namely, polarography[1,2], labelled oxygen[3,4], enzyme investigations[5,6], and electron microscopy[7–9]. Nevertheless, the physiological role of this factor in the oxygen regime of the plant's roots remains unresolved and the data obtained in different laboratories vary.

Here we introduce a chemiluminescent method for tackling this problem. The phenomenon of an ultraweak glow (UG), or biochemiluminescence, discovered by Italian scientists[10], takes place in plant and animal tissues only in the presence of oxygen[11]. We chose this glowing of the roots, or the lack of it in anaerobic conditions, as a test for the transport of oxygen from the shoots to the radical zone of the pumpkin.

The roots of 25 pumpkin seedlings, 4–5 d old with expanded cotyledons, were submerged in Knop's solution. They were about 7–8 cm long and the solution level came to about 0.5–1 cm above the point of root attachment to the shoot—the rest of the shoot remaining in air. The intensity of the root UG (450–650 nm with a maximum of 530 nm) was measured, mainly from the middle and lower parts of the roots, by means of a quantometer apparatus. Experimental details will be described in full later.

When air was bubbling through the solution, a UG of the root was seen but when nitrogen was bubbled through the solution the intensity of the UG began to decrease sharply and after 2 h had practically ceased (Fig. 1). Stopping the passage of nitrogen failed to change the picture even though the shoots remained in air. Only the repeated bubbling of air through the solution led to a rapid increase of the roots' UG.

It is worth noting that other investigators have demonstrated that in the pumpkin[12] and other mesophytes[13,14], oxygen is not only transported from the parts of the plant above the ground to the roots but also partially flows out from the roots to the environment. Further studies of the factors responsible for these discrepancies are being made.

Cell-free studies of developmental changes in synthesis of α-foetoprotein and albumin in the mouse liver

ALPHA foetoprotein (αFP) is an α-globulin present in foetal and early postnatal sera of various animal species. It is not normally detectable in adult serum by the immunodiffusion test, but in several pathological conditions, particularly primary hepatomas, the level of αFP increases to a significant level. The potential use of this phenomenon in early diagnosis of hepatomas has been explored. These and related studies on αFP and other 'foetal-tumour antigens' have been reviewed recently[1–5].

In addition to the possible clinical application, αFP may provide an unique opportunity for the understanding of the relationship between embryonic development and malignant transformation. It has been shown that αFP is synthesised in the yolk sac and liver, but the basic mechanisms for the synthesis and its regulation are essentially unknown. This

problem would best be approached by the use of cell-free systems in which all the requirements for the synthesis of αFP can be analysed.

As an initial step toward this goal, we attempted the synthesis of αFP in cell-free liver extracts derived from foetal and postnatal mice. We describe here that such extracts can produce αFP and albumin in relative amounts which vary depending on the stage of development of mice from which the liver extract was prepared.

Foetuses were removed from Swiss albino mice by caesarean section and killed by decapitation. The liver was quickly removed and ground manually in a glass homogeniser in 20 mM Tris-HCl buffer, *p*H 7.8, containing 5 mM $MgCl_2$, 100 mM KCl, 6 mM β-mercaptoethanol, 0.5 mM dithioerythritol (DTE), 1 mM EDTA and 0.25 M sucrose. The homogenate was centrifuged at 3,000*g* for 15 min and the supernatant was applied to a Sephadex G-25 column in 20 mM Tris-HCl, *p*H 7.8, containing 4 mM $MgCl_2$, 55 mM KCl, 6 mM β-mercaptoethanol, 0.5 mM DTE and 1 mM EDTA. The void volume fraction was incubated with radioactive amino acids and other components necessary for protein synthesis as described in the legend of Fig. 1.

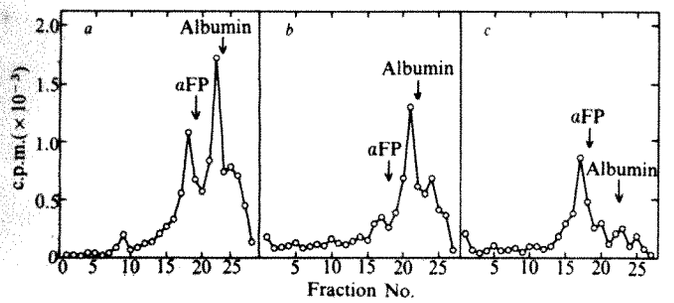

Fig. 1 Polyacrylamide gel electrophoresis of αFP and albumin produced by foetal liver lysate and their identification by immunoprecipitation. *a*, A lysate of 18 d-old foetal liver was incubated with 20 μCi each of ^{3}H-leucine (1 Ci mmol^{-1}), ^{3}H-valine (2 Ci mmol^{-1}) and ^{3}H-phenylalanine (6.15 Ci mmol^{-1}) (Amersham/Searle, Oakville, Ontario), 0.025 μmol each of 17 other amino acids, 1 μmol ATP, 0.3 μmol GTP, 10 μmol phosphocreatine, and 50 μg creatine phosphokinase ml^{-1} at 30° C for 60 min. At the end of incubation the reaction mixture was centrifuged at 149,000*g* for 90 min. The pellet was resuspended in water, frozen and thawed and then sonically disrupted in a Bronson Sonifier at setting 5 for 5 min. This was then centrifuged at 149,000*g* for 90 min and the supernatant was analysed by polyacrylamide gel electrophoresis (7% gel, *p*H 8.9) according to Davis[12]. The gel was stained with Amido Black, scanned at 650 mμ and then sliced into 2 mm fractions which were dissolved in 30% H_2O_2 at 60° C overnight. Radioactivity was measured using Aquasol scintillation liquid (NEN Canada, Dorval, Quebec). *b*, The sample shown in *a* was incubated with rabbit antiserum against mouse αFP at 37° C for 60 min and then at 0° C overnight. The precipitate was removed by centrifugation and the supernatant analysed by polyacrylamide gel electrophoresis. *c*, The sample shown in *a* was incubated with rabbit antiserum against adult mouse serum (Nutritional Biochemical Corporation, Cleveland, Ohio) as described in *b*. The precipitate was removed by centrifugation and the supernatant analysed by polyacrylamide gel electrophoresis. Arrows indicate the carrier αFP and albumin bands.

There was active protein synthesis in these conditions as measured by hot trichloroacetic acid-precipitable counts. Preliminary analysis showed, however, that newly-synthesised radioactive αFP was not released free into the supernatant. This suggested that αFP was synthesised by membrane-bound polysomes and the completed polypeptide chains remained bound to the membrane or in microsomal cisternae. Several treatments were tested to disrupt the membrane structure. A combination of freeze-thawing and sonication was found to be among the most effective for this purpose. This procedure also permits the release of newly formed albumin from inside the microsomal cisternae.

Polyacrylamide gel electrophoretic analysis of proteins synthesised by 18 d foetal liver extract and subsequently released by sonication is shown in Fig. 1*a*. Two main radioactive fractions were observed which showed slightly lower mobility than carrier αFP and albumin. To identify these proteins the sample was divided into two portions; one received antiserum against αFP and the other antiserum against adult mouse serum (to precipitate albumin). These antisera possessed the required specificity to αFP and adult serum proteins as tested by double immunodiffusion and immunoelectrophoresis.

After incubation, antigen–antibody precipitates were removed and the supernatant containing proteins not bound to antibody was analysed by polyacrylamide gel electrophoresis. In the sample which received antiserum against αFP the faster-moving fraction remained as the major radioactive peak (Fig. 1*b*). In the other sample which received antiserum against adult mouse serum, the slower moving fraction remained as the major radioactive peak (Fig. 1*c*). This indicated that the faster moving radioactive protein was albumin and the slower moving protein αFP.

Mouse αFP has been shown to exhibit microheterogeneity or several electrophoretic forms due to a variation in the amount of sialic acid residues[6]. As the sialation process is distinct from the synthesis of polypeptide chains it is possible that αFP produced in the cell-free system was not fully sialated and thus exhibited a lower electrophoretic mobility than carrier αFP. The exact cause for the slightly slower migration of radioactive albumin than carrier albumin is not clear at present, but a similar observation has been reported by others[7].

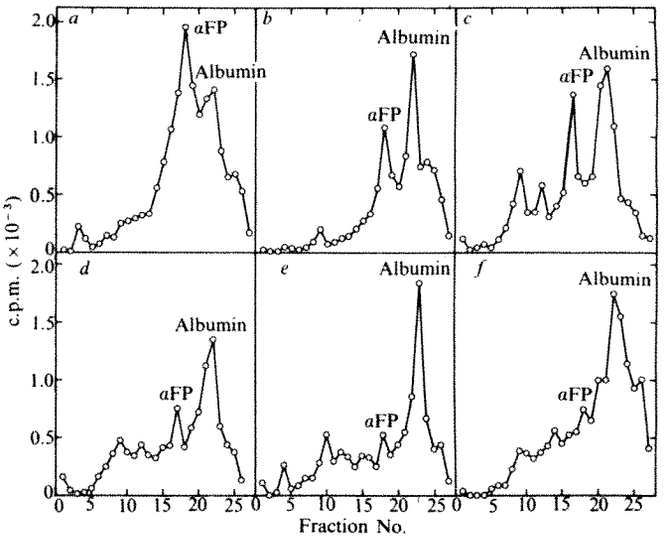

Fig. 2 Polyacrylamide gel electrophoresis of proteins produced by liver lysates from foetal and postnatal mice. Conditions for cell-free protein synthesis and gel analysis are described in the legend of Fig. 1. *a*, 13-d-old foetus; *b*, 17-d-old foetus; *c*, 20-d-old foetus; *d*, 1-d-old mice; *e*, 3-d-old mice; *f*, 6-d-old mice.

Figure 2 shows the synthesis of αFP and albumin in liver extracts from developing mice ranging in age from 13 d of gestation to 6 d after birth. It is seen that the synthesis of αFP decreased with time, whereas that of albumin increased. We found that, although the total radioactive proteins released by sonication varied from experiment to experiment, the % of αFP and albumin and their relative amounts remained relatively constant. The molecular weight of mouse αFP, as estimated by sodium dodecyl sulphate (SDS) gel electrophoresis, was 70,000, which was similar to that of mouse albumin (unpublished data). The radioactivity in the αFP and albumin fractions shown in Fig. 2 is, therefore,

directly proportional to the total amounts synthesised in the cell-free extracts.

The changes in the synthesis of αFP and albumin shown above were calculated as relative amounts and are presented in Fig. 3. in the 13-d-old foetus, the synthesis of αFP was twice as active as that of albumin. The subsequent decrease in αFP production and increase in albumin synthesis showed that at about day 15 of gestation they were produced at about an equal rate. By the time the mice were born the αFP:albumin ratio decreased to less than 1:2. After birth, the synthesis of αFP continued to decline and seemed to cease after about one week as analysed by the present method.

The level of albumin synthesis was remarkably high in the foetus of 13 d gestation. Analysis of the liver in the earlier gestation was not feasible because of its small size.

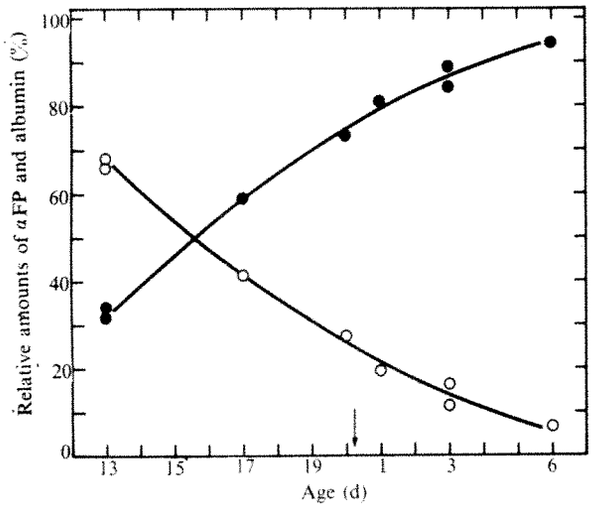

Fig. 3 Relative amounts of αFP and albumin synthesised by liver lysates from foetal and postnatal mice. The sum of the counts under αFP and albumin peaks in Fig. 2 was used as 100%. ○, αFP; ●, albumin. Arrow indicates birth.

The results described above show that the present cell-free system enables the analysis of relative synthetic activity for αFP synthesis and albumin production in the liver at various stages of development. The observed shift in the synthetic activities with maturation is in agreement with the changes in their total serum contents based on immunological analysis[8]. It is likely, therefore, that the present cellfree synthesis of αFP and albumin reflects the pattern of protein synthesis operative *in vivo*. A similar approach can be applicable to other mammalian species, and may prove to be of value as an aid in diagnosis of hepatomas.

The present study suggests that mRNA for αFP may be isolated from foetal liver and translated in a defined cell-free system. In fact, the study in progress has strongly supported this possibility. The synthesis of albumin using exogenous mRNA has recently been accomplished[9–11]. The study of requirements for the translation of these mRNAs, such as initiation factors, should help us to understand the molecular basis for the regulation of the αFP and albumin synthesis during embryonic development. The knowledge gained in such studies may also provide a basis for possible engineering of the synthetic events in tumour cells to arrest or reverse neoplastic transformation.

We thank Dr T. A. McPherson for reading the manuscript and John Arlette for assistance in the preparation of antisera. This work was supported by funds from the National Cancer Institute of Canada and the Medical Research Council of Canada.

Blocking of syngeneic effector T cells by soluble tumour antigens

THE cellular immune response to murine sarcoma virus (MSV)-induced tumours in mice involves lymphoid effector cells of different origins[1,2]. When the chromium release test (CRT)[3–5] is used to study this immune response, only thymus-derived lymphoid cells (T cells) show any appreciable lytic activity towards the appropriate tumour target cells[6,7]. Other lymphoid cells display no lytic activity in CRT, nor are they required for T cell-dependent tumour cell lysis to occur[7]. When the microcytotoxicity assay (MA) of Takasugi and Klein[8] is used to study the cellular immune response of the same MSV tumour-bearing mice, both T and non-T lymphoid cells are seen to be active[1,2].

A time-course study with these two assays using the same lymphoid cell preparations[1] showed that, at the moment of maximum tumour size, neither T nor non-T lymphoid cell activity was detected in MA, whereas a peak value of T cell activity was detected in CRT. It has also been shown that sera from MSV tumour-bearing mice (progressor sera) are able to completely inhibit the immune activity measured in MA[1,9], although the same sera have no effect when tested in CRT[1,4,6]. These facts indicated that a different cytotoxic T cell subpopulation might be involved in each test, the effector T cells active in MA probably being blocked by the soluble tumour antigens present in progressor sera[9,10] and the effector cells active in CRT not being at all affected. Here we present further arguments in favour of such an hypothesis.

We tested the effect of progressor sera or soluble tumour-cell antigen extracts on the immune activity of spleen cells from MSV-infected C57BL/6 (B6) mice, as revealed by MA and CRT. The Moloney isolate of MSV, regularly maintained by acellular transmission in newborn B6-mice, was used in all experiments to induce experimental sarcomas in adult B6 mice. Spleen cells were taken between the 15th and 25th days after MSV inoculation because the T cell subpopulation shows an appreciable immune activity in both MA and CRT during this period[1,2], and the tumour has regressed. CRT and MA were performed as previously described[1,4], and syngeneic conditions were maintained throughout all experiments. Spleen lymphocytes

from normal B6 mice were used as negative controls in all tests.

The experiments summarised in Table 1 investigated the blocking activity of B6 progressor serum (PrSm) on spleen effector cells. The cytostatic activity detected in MA could be blocked at a limited range of serum dilutions (1/6-1/12), while no effect was evident in CRT with the same lymphocyte samples and serum dilutions. Normal B6 serum (N1 Sm), at similar dilutions, did not affect the lymphocyte activity in either test.

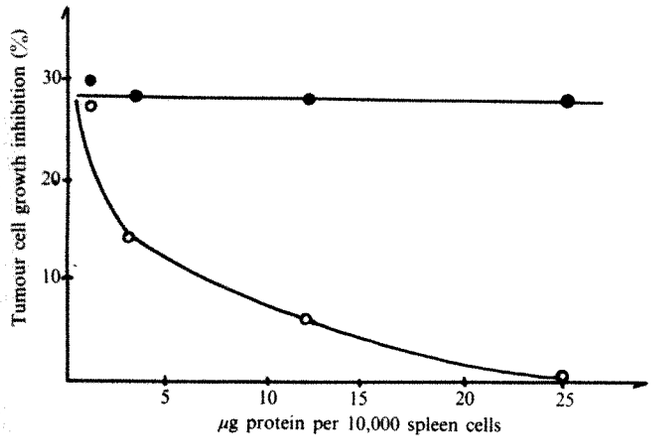

Fig. 1 The effect of GiL4 antigen (O) and of normal B6 antigen (●) on the immune activity, as detected in MA, of spleen cells from B6 mice infected with MSV 20 d previously.

Baldwin *et al.*[11] have shown that the blocking fraction of serum from tumour-bearing rats contains antigen-antibody complexes, and that solubilised tumour antigen seems to be the main blocking agent[10,11]. Sjögren *et al.*[12] had previously reached the same conclusion concerning the blocking factor in sera from MSV-infected mice. We therefore solubilised tumour cell antigens and checked whether they could block specifically the spleen cell activity detected in MA and in CRT.

The procedure developed by Mettzer *et al.*[13] and Reisfeld *et al.*[14] was chosen; this involves antigen solubilisation by 3 M KCl, *p*H 7.4, and gives high yields of functional antigen. Soluble antigens were prepared from normal spleen cells or from several different tumour cell lines belonging to the FMRGi antigen group[15] (MSV-tumour cells are FMRGi-positive). Normal or immune spleen lymphocytes were incubated for 18 h (CRT) or 48 h (MA) in the presence of target tumour cells and of antigen extract. As shown in Table 2 the cytostatic activity of immune spleen cells in MA was inhibited by the tumour antigen extracts prepared from GiL_4, MSV-tumour, or Friend leukaemia cells. No blocking effect was detected in CRT at equivalent antigen doses; indeed, in some cases immune lysis actually increased in CRT in the presence of soluble antigen.

Inhibition by the soluble antigen preparations in MA is specific because: first, the soluble extracts prepared from normal B6 or BALB/c spleen cells do not block the cytostatic activity of anti-MSV tumour lymphocytes at any of the doses used; second, when an allogeneic immune system is studied in MA, the B6 'normal' extract blocks BALB/c lymphocytes (H2d) immunised against B6 normal spleen cells (H2b) (Table 3); and third, the BALB/c soluble extract prepared from Friend virus-induced leukaemia cells blocks the activity in MA of B6 lymphocytes immunised against an MSV-induced tumour (Table 2), but it does not affect the activity in MA of BALB/c anti-B6 lymphocytes (Table 3). This also indicates that the inhibitory activity of our antigen extracts is not the result of a toxic effect on spleen cells.

The blocking effect displayed by the soluble antigen extracts in MA follows a dose-response curve (Fig. 1). The extract prepared from GiL4 cells blocks lymphocyte activity completely at doses equivalent to or higher than 25 μg protein per 10,000 spleen cells; blocking activity can still be detected at 3 μg protein per 10,000 spleen cells, but disappears at the 1 μg protein level.

The experiments discussed above show that the immune cytostatic activity of lymphoid cells in MA can be blocked when functional T and non-T effector cells are present[1,2]. As the effector cells involved in CRT are exclusively T cells[4,6,7] and cannot be blocked, it seemed important to determine if the effector T cells active in MA, when purified, could be blocked or not. Cell populations enriched in T cells were consequently obtained by passing whole spleen cell suspensions through anti-immunoglobulin coated glass bead columns[1,16] and were subsequently used to study the blocking effects of progressor sera and of soluble antigen extracts. Table 4 shows that column-purified cells can be effectively blocked in MA when they are incubated with progressor serum or with the adequate soluble tumour extract. No decrease in immune lysis is detected in CRT when the same lymphocytes are incubated with these reagents at comparative doses.

Our column-purified cell preparations contained 89 ± 2% θ_{C3H} positive cells and 1 ± 0.5% immunoglobulin-positive cells[7]. To study the role played in MA by the θ_{C3H} negative cells present in the column-purified cell suspensions, column-passed cells were treated, with AKR anti-θ_{C3H} serum and rabbit complement and dead cells were removed by incubation with 0.05% trypsin. A pure population of viable column-passed cells not carrying the θ_{C3H} antigen was thus obtained and was adjusted to the appropriate cell number before distribution in the MA plates. These spleen cells possessed no ability to inhibit tumour cell growth; experimental results published recently[1,2] show that non-T cells do not require a T cell collaboration to exert a cytostatic effect in MA. Control cells trypsinised in the same manner after incubation with normal AKR serum and complement showed no decrease in their immune cytostatic activity. Consequently, the immune activity displayed by such column-purified cells in MA seems to be due exclusively to thymus-dependent lymphocytes.

In a different set of experiments, cytostatic non-T cells were purified by treating whole spleen cell preparations with anti-θ_{C3H} serum and complement. The immune activity of 10,000 anti-MSV non-T cells was completely inhibited in MA by B6 progressor serum diluted 1/6 or by 25 μg GiL4 soluble antigen. Normal B6 serum and normal B6 antigen had no effect on the immune activity of these cells.

Our results provide further proof of the hypothesis that CRT and MA, as performed here, do not measure the same immune phenomena. As suggested in a recent communication[1], CRT reveals an exclusively T cell-mediated cytolysis, while MA seems to detect a complex cytostatic effect in our experimental conditions. This segregation of effector cell functions is probably because the target cell used in MA is highly resistant to immune cytolysis, while the target cell used in CRT is easily lysed[1]. We have provided evidence here which shows that soluble antigens prepared from MSV-induced tumours or from antigenically related tumours can block the activity of anti-MSV effector T cells in MA, whereas no inhibition of the effector T cells active in CRT can be detected. The possibility of blocking immune activity in MA with soluble tumour antigen preparations has already been indicated by Baldwin *et al.*[10,11] in other tumour systems. C. Neauport (unpublished) has recently obtained results in our laboratory showing that the activity of anti-allogeneic immune lymphocytes in CRT is very difficult to block with soluble antigen preparations, differing with results published by Wagner and Boyle[17] and agreeing with previous observations of Cerottini *et al.*[18]. We have also provided evidence that progressor sera can only block the activity of effector T cells in MA and not in CRT, thus confirming previous observations[1,4,9]. This blocking effect could result from the presence of soluble tumour antigens in the serum of progressor mice, and it might explain why no activity can be detected in MA when lymphocytes are taken at the time of maximum tumour size[1]. The fact that the effector T cells de-

Normal or immune B6 spleen cells were incubated with normal B6 serum (NlSm) or B6 progressor serum (PrSm) for the duration of each test. In MA, 3034 Falcon Plastics tissue culture microplates were seeded with 100 to 200 B6 MSV tumour cells growing in monolayers and were incubated overnight; 5µl Eagle's MEM, NlSm or PrSm plus 10,000 lymphocytes in 5 µl were then added, and the plates were further incubated at 37°C for 48 h. After one wash, the remaining cells were fixed with methanol, stained with giemsa and counted. The numbers shown represent the arithmetic mean of target cell counts ± s.d. and the significance of the relative inhibition of cell growth was calculated according to Student's *t* test. The degree of blocking in MA was evaluated by taking into consideration the difference between the number of target cells counted in the presence of immune spleen cells and of normal spleen cells (ΔTC) following incubation with progressor serum (ΔTC_{PrSm}) or with normal B6 serum (ΔTC_{NlSm}): Degree of blocking (%) = $(\Delta TC_{NlSm} - \Delta TC_{PrSm})/(\Delta TC_{nlsm}) \times 100$.

In CRT 20,000 ^{51}Cr-labelled B6 GiL4 ascitis lymphona cells in 0.05 ml were mixed with 0.1 ml MEM, NlSm or PrSm, and 500,000 normal or immune B6 spleen cells in 0.05 ml were then added. After 18 h of incubation the reaction mixture was adjusted to 1.0 ml and percent chromium release was determined as described elsewhere[7]. The results shown represent the differences between chromium released in the presence of immune spleen cells and of normal spleen cells ± s.d., and are statistically significant. A low lymphocyte to target cell ratio (25:1) was chosen to give low levels of immune lysis which theoretically should be easily blocked. No blocking effects were detected with CRT in any of the samples studied.

Normal or immune spleen cells were incubated with each soluble antigen preparation during the whole duration of each test at the ratio of 25 or 12 µg protein for 10,000 lymphocytes. MA and CRT were performed as described in Table 1. Soluble antigens were prepared from B6 normal spleen cells (B6NlAg), BALB/c normal spleen cells (CNlAg), GiL4 lymphoma cells of B6 origin (GiL4Ag), solid B6 MSV-induced tumours (B6MSVAg), YC8 lymphoma cells of BALB/c origin (YC8 Ag), and Friend virus-induced leukaemia cells of BALB/c origin (FVL Ag). Following solubilisation in 3M KCL, *p*H 7.4, the crude soluble antigen preparations were filtered through Sephadex G-200 columns; the fractions presenting antigenic activity were detected by the specific inhibition of cytotoxic antisera in the presence of complement, and their protein content was evaluated with the Folin-Ciocalteu reagent.

tected in CRT are not sensitive to such blocking factors further indicates that two different effector T cell subpopulations are involved here. These two effector T-cell subpopulations probably differ in function as well as in sensitivity to blocking factors, since the subpopulation detected in CRT displays a cytolytic activity and the subpopulation detected in MA displays a cytostatic activity. These observations recall the functional heterogeneity of T cells detected in other immune systems[19-21]. It cannot be definitely excluded, however, that in our experimental system effector T cell subpopulations of similar nature are involved which react with different antigens of the tumour cell membrane.

Table 2 Relative cytotoxic potency and blast cell content of cultures following *in vitro* cultivation of C57BL/6J lymph node cells with different stimulating spleen cell populations

Composition and density of stimulating spleen cell population*		Blast cell content after 4 d in culture	Relative cytotoxic potency†
8×10^6 ml^{-1}	2×10^6 ml^{-1}		
γ-irradiated BALB/c	Ultraviolet-irradiated C57BL/6J	+++	300
Ultraviolet-irradiated BALB/c	γ-irradiated C57BL/6J	—	⩽1
Ultraviolet-irradiated BALB/c	γ-irradiated CBA/H	++	50
Ultraviolet-irradiated C57BL/6J	γ-irradiated CBA/H	+	10

* Stimulating spleen cell populations were prepared by mixing equal volumes of each component at the densities shown. *In vitro* cultures were then prepared by mixing 5 ml of the stimulating cell population with 5 ml of C57BL/6J lymph node cells at a density of 4×10^6 ml^{-1}.

† Relative potencies were calculated from Fig. 2 by measuring the displacement along the abscissa of the different dose response relationships. The potency of the cultures stimulated with ultraviolet-irradiated BALB/c spleen cells was arbitrarily taken to be equal to or less than unity.

The displacement along the abscissa of the dose response relationship obtained from different cell populations is a measure of their relative potency.

These experimental findings were reproducible. γ-Irradiated BALB/c spleen cells produce a vigorous blast cell response when cultured with C57BL/6J lymph node cells, and generate a high titre of cytotoxic cells specific for the H-2^d antigen. Ultraviolet-irradiated BALB/c spleen cells, in contrast, produce no detectable cytotoxic response and no blast transformation. When γ-irradiated CBA/H spleen cells were added to cultures of ultraviolet irradiated BALB/c spleen cells and C57BL/6J lymph node cells, however, blast transformation was evident and the cytotoxic cell response to the H-2^d antigen was increased by five-fold over the CBA/H background.

The *in vitro* production of cytotoxic lymphocytes has been shown to be a function of activated T cells [8]. Thus, the above data indicate that transplantation antigens presented on the surface of the ultraviolet-irradiated lymphoid cells are poorly immunogenic for T cells *in vitro*. The *in vitro* immunogenicity of this antigen is significantly enhanced, however, if the responsive cells receive an allogeneic stimulus at the same time as they are confronted with antigen. These findings confirm our earlier *in vivo* studies showing that allogeneic transplantation antigens are relatively weak in the absence of allogeneic stimulation[1, 9]. They also raise the possibility that antigenic differences between donor and recipient may not constitute a major barrier to allotransplantation.

According to our hypothesis[1], lymphoid cells carried in the transplanted organ or tissue may effectively constitute the major transplantation barrier because of the way in which they influence the immunogenicity of transplantation antigen.

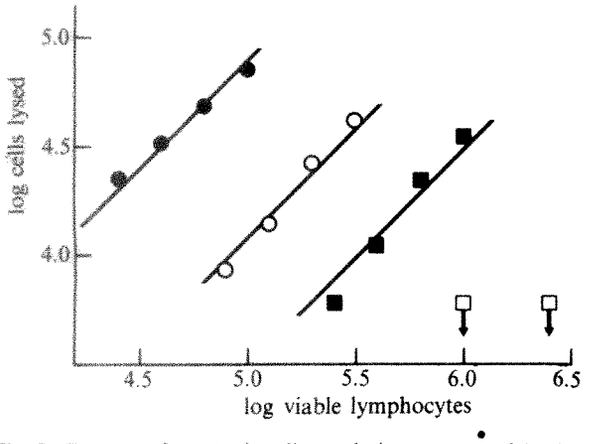

Fig. 2 Potency of cytotoxic cell populations generated *in vitro*. C57BL/6J lymph node cells were stimulated with the following spleen cell populations: ●, γ-irradiated BALB/c + ultraviolet-irradiated C57BL/6J; □, ultraviolet-irradiated BALB/c + γ-irradiated C57BL/6J; ○, ultraviolet-irradiated BALB/c + γ-irradiated CBA/H; ■, ultraviolet-irradiated C57BL/6J + γ-irradiated CBA/H. Cell populations were assayed against 2×10^6 P815 mastocytoma target cells.

Cannabinoid content of some English reefers

THIS paper reports the results of qualitative and quantitative analysis of 36 reefers or 'pro-reefers' (samples of herbal or resin cannabis sufficient for one reefer) produced in London and Leeds. As far as we know it is the first time reefers in actual use have been so analysed. The reefers were obtained from three different groups: group A, regular smokers in the London area, some of whom had asked for psychiatric help; group B, regular users in Leeds, none of whom had sought medical advice about their cannabis smoking; group C, casual users in the London area. The results show a very wide variation in potency and indicate that more than half were below the threshold dose.

The contents of each reefer were weighed, examined macroscopically and microscopically and analysed[1] quantitatively for the main cannabinoid THC (Δ^1-tetrahydrocannabinol), CBN (cannabinol) and CBD (cannabidiol) (Table 1). Almost all the reefers contained tobacco mixed with varying proportions of resin or herbal cannabis which, when possible, was separated and weighed.

We found a very high variation in potency, the content of the psychoactive substance THC varying from 0.15 mg to 41.1 mg.

Allogeneic stimulation modulates the *in vitro* response of T cells to transplantation antigen

THE theory of allogeneic stimulation[1] postulates that transplantation antigens, such as H-2 in the mouse or H-LA in man, are not strong immunogens for allogeneic animals, but are rendered highly immunogenic when presented to the immune system in conjunction with an allogeneic stimulus. The capacity to provide an allogeneic stimulus is the property of metabolically active[2-4] immunocompetent cells[1], and it has been suggested that allogeneic stimulation requires the transfer of some cytoplasmic component from the stimulating to the responsive cell[1]. According to this hypothesis, any treatment that inactivates the metabolic activity of lymphoid cells will reduce their immunogenicity for other members of the same species.

A prediction of this hypothesis is that transplantation antigen alone, either soluble or cell bound, will be poorly immunogenic when presented to potentially responsive immunocompetent cells. If an allogeneic stimulus is provided at the same time, however, this second stimulus will activate the potentially reactive cell and facilitate its response to the test antigen. Here we show that lymphocytes inactivated with ultraviolet light are unable to stimulate allogeneic lymphocytes in mixed leukocyte culture (MLC), and do not generate a significant cell-mediated cytotoxic response in such cultures. Cytotoxic activity can, however, be generated if an allogeneic stimulus is provided by a third party, γ-irradiated lymphocyte that is antigenically different from the ultraviolet-irradiated cell.

MLC reactivity was assayed by mixing responsive lymph node cells (C57BL/6J) with γ- or ultraviolet-irradiated stimulating spleen cells (BALB/c) in Linbro multi-dish culture trays Linbro FB 24-TC). The culture medium used was Eagle's Minimum Essential Medium (Grand Island Co., F15) containing penicillin (100 μg ml^{-1}), streptomycin (100 μg ml^{-1}) and neomycin (100 μg ml^{-1}). The medium was supplemented with 10% foetal calf serum and 2-mercaptoethanol to a final concentration of 10^{-4} M. Stimulating spleen cells, at a density of 1×10^7 ml^{-1}, were incubated in culture medium for 1.5 h at 37°C before irradiation[5]. ^{60}Co γ-irradiation (800 r) was given at a dose rate of 280 r min^{-1} and ultraviolet irradiation was given by exposing 5 ml of cell suspension in open 80 mm Petri dishes for 4 min, at a distance of 20 cm from a 30 W germicidal ultraviolet lamp. Following irradiation, the cells were washed once and resuspended in culture medium.

To control the specificity of MLC activation, and any nonspecific effects resulting from the addition of ultraviolet-irradiated cells to the test cultures, the following spleen cell mixtures were used as the stimulating population in MLC: γ-irradiated BALB/c + ultraviolet-irradiated C57BL/6J; ultraviolet-irradiated BALB/c + γ-irradiated C57BL/6J; and ultraviolet-irradiated C57BL/6J + γ-irradiated C57BL/6J. These stimulating cell populations were prepared by mixing equal volumes of each component at a cell density of 2×10^6 ml^{-1}. In MLC assays the stimulating spleen cell population was mixed with an equal volume of C57BL/6J lymph node cells at a density of 1×10^6 ml^{-1}. Each mixture (2.5 ml) was added to three replicate wells of Linbro culture trays and cultured for the required time at 37°C in an atmosphere of 10% CO_2, 7% O_2 and 83% N_2. Aliquots (0.2 ml) were taken from each culture over a 5 d period and added to Linbro 16 mm microtitre plates with 3 μCi of ^3H-thymidine (Amersham, TRA 120, specific activity, 5 Ci $mmol^{-1}$). Thymidine uptake was estimated 5 h later by collecting the cultured cells on glass fibre filter disks, using an automatic cell collecting device (MASH-11, Microbiological Associates), and counting the amount of thymidine incorporation in a liquid scintillation counter.

The kinetics of thymidine uptake are shown in Fig. 1. Ultraviolet irradiation of BALB/c spleen cells, in contrast to γ-irradiation, inactivates their capacity to provide an allogeneic stimulus for C57BL/6J lymph node cells as measured by MLC activation. These findings confirm those of Lindahl-Kiessling *et al.*[4]. Moreover, ultraviolet irradiation did not affect the expression of alloantigen on the surface of irradiated cells (Table 1), as determined by antibody absorption. Antigenic activity was estimated by microcytotoxicity titration before and after absorption of alloantiserum with γ- or ultraviolet-irradiated BALB/c spleen cells.

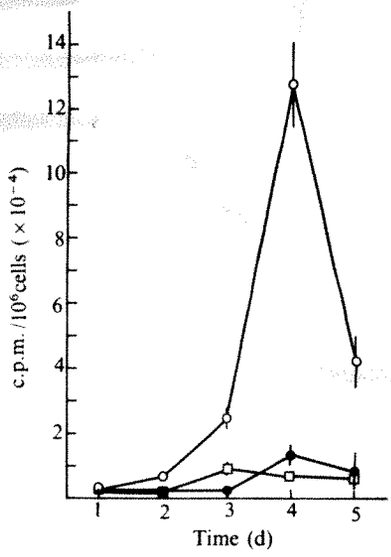

Fig. 1 Stimulation of ^3H-thymidine uptake by C57Bl/6J lymph node cells in mixed cultures containing the following spleen cell populations: ○, γ-irradiated BALB/c + ultraviolet-irradiated C57BL/6J; ●, ultraviolet-irradiated BALB/c + γ-irradiated C57BL/6J; □, γ-irradiated C57BL/6J + ultraviolet-irradiated C57BL/6J. ^3H-thymidine incorporation is expressed as c.p.m./10^6 lymph node cells and the vertical bars show the standard error of the mean of three replicate assays.

The *in vitro* generation of cytotoxic lymphocytes was carried out in Falcon plastic tissue culture flasks (30 ml), using the MLC medium described above. Ultraviolet-irradiated BALB/c ($H\text{-}2^d$) spleen cells, either alone or mixed with γ-irradiated CBA/H ($H\text{-}2^k$) spleen cells, were used to stimulate C57BL/6J ($H\text{-}2^b$) lymph node cells *in vitro*. After 4 d, the cultures were examined microscopically and the blast cell content scored semiquantitatively. These cultures were then collected and

Table 1 Antibody binding capacity* of γ- and ultraviolet-irradiated BALB/c spleen cells

Absorbing spleen cell population (10^7 cells)	Cytotoxic titre
γ-irradiated BALB/c	1 : 10
Ultraviolet-irradiated BALB/c	1 : 10
γ-irradiated C57BL/6J	1 : 160
Ultraviolet-irradiated C57BL/6J	1 : 160

* Cytotoxic anti-BALB/c antibody was prepared in C57BL/6J mice. 0.5 ml of antiserum was absorbed with the different cell populations for 2 h at room temperature. Residual cytotoxic activity was assayed against BALB/c lymph node cells, in the presence of guinea pig complement. Antibody titrations were carried out with doubling dilutions of serum and the 50% cytotoxicity end point was estimated by trypan blue exclusion.

cytotoxic cells specific for the $H\text{-}2^d$ antigen assayed against ^{51}Cr-labelled P815 mastocytoma ($H\text{-}2^d$) target cells[6]. Table 2 shows the detailed experimental protocol, including controls for specificity and any nonspecific effects of ultraviolet-irradiated cells, and the relative potencies of the resultant cytotoxic cell populations. Cytotoxic potency was obtained by plotting the logarithm of the number of target cells lysed against the logarithm of the number of sensitised cells used in the assay (Fig. 2). Such plots have a linear dose response relationship with unit slope to a level of approximately 35% specific lysis[7].

As this variation has been found in only 36 samples, it is almost certain that similar or greater variation occurs regularly. In view of the known variability in the THC content of the plant (*Cannabis sativa L.*) from which the drug is obtained, the instability of the active constituents, especially in badly prepared and stored material and the 'unstandardised' conditions in which the drug is distributed the variation is perhaps not surprising. The lack of standardisation means that a casual smoker, used to low doses, may be accidentally exposed to highly potent material.

On average each reefer in groups A and C was smoked by two people (Table 2) so that the mean dose of THC per person in group A would be 4 mg (range 0.1 to 14 mg); and in group C would be 2.2 mg (0.5–5.0 mg). For group B, with an average of three people per reefer, the dose would be 3.5 mg (0.2–13 mg). These doses are lower than those used by such workers as Neumeyer and Shagoury[2] (2–9 mg) and Isbell *et al.*[3], who quote 3.5 mg as a threshold dose and 16.2 mg sufficient to produce distinct depersonalisation. On this basis about two-thirds of the reefers, when shared, would produce effects less than that of the threshold value of 3.5 mg THC. Casual smokers may therefore be exposed to extremely small doses and so may falsely assume that cannabis is a relatively harmless substance. Conclusions based on questionnaires to smokers[4], such as students, are probably of little value unless adequate information on the potency of the reefer is also obtained.

Table 1 Components and analytical data on reefers

Reefer No.	Contents (apart from tobacco*)	Weight including tobacco (g)	Cannabinoids (mg) THC	CBN	CBD
Group A					
1	Soft resin: (0.214 g)	0.744	28.39	traces	16.68
2	Soft resin	0.752	24.98	traces	14.65

35	2*	3	0.1
36	2*	3	0.1

* (per week)

All these doses refer to the actual amounts of THC in the reefers; obviously the amount reaching the blood stream will be affected by the manner in which the reefer is made and, more importantly, whether the user inhales and if he does how long he holds the smoke before expelling it[5].

A more important variable is the actual number of reefers smoked by an individual per week. By careful questioning group A was found to consume 3.8 g cannabis per person per d (range 2 g to 6 g); group C 0.3 g (range 0.1 g to 1 g). For group B drug histories were collected using the techniques of participant observation[6] and actual weighing of the amounts used. The average amount was 2.8 g per person per d (range 0.3 g to 8.3 g). As the reefers (Table 1) were collected at the time this information was obtained, it is possible to calculate the daily intake of THC on the assumption that the reefer analysed represented those being smoked at that time. The results (Table 2) show that for group A the average daily dose of THC is 60 mg per person, for group B 26 mg per person and for group C 8 mg. If the first two extremely high values of group A are removed the average for the remainder is 37 mg per person. Although these first two values are high they are not dissimilar from the values of 150 mg THC d^{-1} quoted by Miras for regular users in Greece[7]. Some users evidently compensate for low potency reefers by smoking 10–20 reefers d^{-1} and in these circumstances the reported carcinogenic effects[8,9] may become significant.

Observation of some individuals, recorded before the analytical results were known, confirms a dose-response relationship. For reefer 15 (41 mg THC per dose) the user admitted he could not smoke more than 1 d^{-1}, otherwise he was unable to co-ordinate his movements. Reefer 22 (36 mg THC d) was from two females whose most characteristic feature was a persistent hilarity; neither was in full time employment. The suppliers of reefers 3 and 8 (17 to 111 mg) were all referred for mild cannabis psychoses, and were depressed and paranoid when smoking heavily. These symptoms disappeared within

2 months of giving up the drug. Reefer 27 (1–3 mg THC d) was from two small subgroups; none of their members exhibited noticeable disorganisation of the cognitive processes and all seemed entirely capable of holding full time employment. They seemed similar to the members of group C (casual smokers) who were in full time study or employment. It is significant that students reduced their intake or gave up the drug altogether before examinations. Subjects who used reefer 28 (glass fragments plus incense) made it from what they had bought as Turkish pollen hash at £18 per ounce. Although they obviously expected a good high they experienced no subjective euphoria; most reported serious headaches instead.

We found no evidence of adulteration except in reefer 28. This indicates that there is currently no shortage of genuine cannabis. Since THC decomposes into the inactive CBN due to faulty preparation and prolonged storage, the relatively high proportion of CBN in the group A reefers compared with group C indicates significant breakdown. This may come as a surprise to group A as they claimed to be nearer the sources of supply of cannabis, and therefore assumed they were using fairly fresh and active material.

Reefer 3 was grown out of doors in Brixton, London, and collected in July. Reefer 12 was grown in Dublin from Nigerian seeds and "harvested too early". Reefer 15 was from seeds taken from Zambian 'bush' and grown on a railway embankment near Leeds; the plants were harvested in September. None of the samples contained the relatively potent flowering tops, yet they had quite high THC content (21.8, 19.8 and 23.9 mg g^{-1} air-dried leaf respectively). These results should therefore dispose of the idea that potent material cannot be grown in a cool climate on unobtrusive sites sometimes with poor lighting conditions. We hope to publish soon details of work on plants grown in this country over several years, which confirm this conclusion. We have already pointed out[10] the defect in the present international definition of cannabis as "the flowering or fruiting tops of the cannabis plant (excluding the seeds and leaves when not accompanied by the tops)"[11].

Some of the reefers used by experienced smokers were low in THC content but nevertheless were claimed by the users to be satisfactory. One possible explanation is the higher average CBD figures for group A (7.0 mg) than for group C (2.1 mg). CBD is said to enhance the effect of THC[12]. Furthermore, since this work began, evidence has accumulated that the GLC peak corresponding to CBD sometimes includes small amounts of other cannabinoids[13]. Synergism cannot be ruled out, and another possible explanation is the presence of noncannabinoid active material in cannabis.

We thank those who supplied us with material and students at University College Hospital, Royal Free Hospital and Bedford College, University of London, who helped to make the necessary contacts in London.

Evolutionary divergences between populations of Australian wild rabbits

The first successful introduction of the European wild rabbit, *Oryctolagus cuniculus*, into Australia took place in 1859 when two dozen animals were imported into Geelong, Victoria[1]. Subsequent minor introductions may have occurred but the evidence indicates that existing populations are derived mainly from the Geelong colony[2]. Rabbit populations now occupy varied environments across the southern two-thirds of Australia[3]. These rabbits provide a good opportunity for the study of evolutionary divergences.

Twenty-six measurements were taken on the skulls of adult rabbits collected from five localities in Australia (Fig. 1). The numbers in each sample were: Tero Creek, 22; Manilla, 12; Tidbinbilla, 20; Holt Rock, 20; Wanneroo, 14. The environments of the localities are diverse. This diversity is reflected in the variations in mean annual rainfalls of the

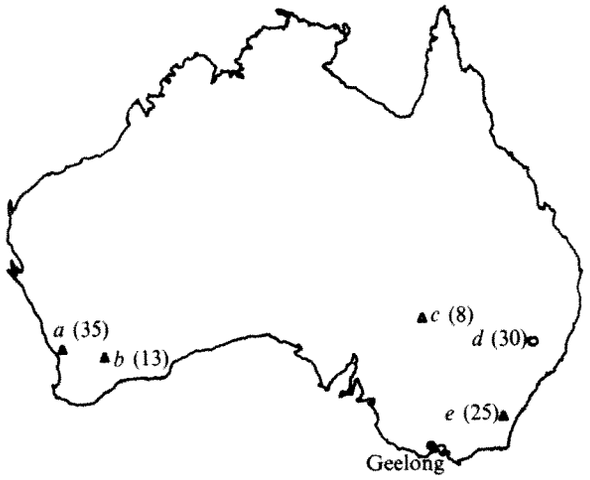

Fig. 1 Locations of collection sites. △ Site of an extant collection; ○, site of the early Manilla sample. The localities are, *a*, Wanneroo, WA; *b*, Holt Rock, WA; *c*, Tero Creek, NSW; *d*, Manilla, NSW; *e*, Tidbinbilla, ACT. The figures in parentheses indicate the approximate mean annual rainfalls (in inches) of the collection sites.

collection sites (Fig. 1). The Manilla sample was collected in 1918 (Australian Museum) and the Tero Creek sample in 1967 (CSIRO). The remainder were captured in 1972 and 1973 using ferrets, traps, spotlights and shooting. We regard all but the Manilla sample as extant.

The metrical parameters consisted largely of standard length, breadth and height measurements of the cranium, mandible and teeth. All parameters were tested for sexual dimorphism using *t* tests but only bizygomatic breadth showed significant sexual dimorphism. This measurement was eliminated from the remaining analyses. Univariate comparisons demonstrated a number of significant differences between all pairs of samples. The number of signifi-

cant t tests (0.05 level) varied from a low of 4 for the Wanneroo-Holt Rock comparison to 16 for the Wanneroo-Tero Creek and Wanneroo-Tidbinbilla comparisons. Over the 10 sample pair comparisons, the mean number of significant t tests was 10 out of 25. The parameters that showed significant differences varied considerably from one pair to the next so that most parameters showed significant heterogeneity in at least one sample pair comparison. Coefficients of variation for all characters in each of the regional samples were calculated. These coefficients generally were low[4], with a mean of 3.8 and range of 1.2–9.6. A preliminary analysis of the same data using Penrose's[5] distance statistics indicates a strong correlation between the geographic and biological distances between sample pairs. This finding is being investigated further.

The appearance of morphological heterogeneity between Australian rabbit populations in such a short time (110 yr) implies a fast rate of evolution. Skulls collected during the early stages of colonisation were not available, but some approximate evolutionary rates were calculated using the two most separated extant samples, Wanneroo and Tidbinbilla. The midpoint between the means of these two samples was taken as the ancestral value of each measurement. Our method requires the working assumption that the extant groups have diverged at the same rate from the hypothetical ancestral population.

Evolutionary rates for all measurements were calculated using Haldane's equation[6], rate $= (\log_e X - \log_e Y)/t$ where $\log_e$ is the natural logarithm, X the mean value of descendants; Y the ancestral mean and t the elapsed time (set at 110 yr). Haldane suggests that the results be expressed in darwins, where one darwin is a change of 1/1,000th part in 1,000 yr. Over all parameters a mean rate of 116 darwins was obtained, with a range of 27–406 darwins. This mean rate of evolution is 5,000–10,000 times the estimated rate in teeth of horses over a period of 5–16 million years (ref. 6). The mean for the rabbit populations however is similar to the rates found for changes in the dental dimensions in a population of the African green monkey (*Cercopithecus aethiops sabaeus*) isolated for 300 yr on the West Indies island of St Kitts[7]. In this case the mean rate was 160 darwins with a range of 10–470 darwins[7]. These rapid rates of evolution would not be expected to continue indefinitely but to slow down as populations approached a genetic equilibrium.

Our results indicate that substantial morphological divergences have developed rapidly between Australian rabbit populations.

Claim that two human linkage groups carry different loci for GPT and LDH withdrawn

CHEN and Giblett[1] have reported the occurrence of genetic polymorphism for human red cell glutamic pyruvic transaminase (GPT; EC 2.6.1.2). The usual phenotypes of red cell GPT (that is, GPT 1, 2-1 and 2) could be identified on cellogel by adapting the starch gel electrophoretic method of Chen and Giblett to cellogel (Fraser *et al.*, unpublished). When a buffer system which separates the human and Chinese hamster forms is used, however, the isozyme patterns formed by fibroblasts were found to be distinctly different from those by red cells. We have employed the fibroblast isozymes as markers in human gene linkage studies using man–Chinese hamster somatic cell hybrids and have reported that the enzyme with GPT activity is probably a tetramer determined by two genes named *GPT B* and *GPT C* located on different chromosomes and linked to *LDH B* and *LDH A* respectively[2].

In a later series of experiments involving further characterisation of the GPT isozymes in the hybrids and their parental cells, we have found strong evidence that the screening procedures used do not score different enzymes (GPT and LDH) but the same gene product (LDH) by different methods.

The principle of staining for GPT is that the enzyme converts alanine and α-ketoglutarate to glutamic acid and pyruvate, and the pyruvate thus formed is detected by coupling it to LDH when NADH is oxidised to NAD[3]. The sites of enzyme activity are seen under long wave ultraviolet light as quenched areas against a fluorescent background. If the appearance of bands was caused by the action of GPT isozymes, an omission of any of the substrates in the reaction mixture should prevent the formation of bands.

It turned out that an omission of alanine alone or alanine and LDH in the reaction mixture did not prevent the appearance of any of the bands seen after staining with the complete GPT reaction mixture. Moreover, a substitution of α-ketoglutarate by pyruvate in the staining mixture resulted in the same electrophoretic pattern. With pyruvate as substrate the bands appeared instantaneously with increased intensity, whereas with α-ketoglutarate the gels had to be incubated at 37°C for at least 30 min for the patterns to become visible.

These observations show that the human and Chinese hamster lactate dehydrogenase isoenzymes are capable of utilising α-ketoglutarate as a substrate analogue in the conditions used and that these conditions are obviously not optimal for the GPT of the species concerned. Therefore, the patterns observed earlier by us[2] on staining for glutamic pyruvic transaminase in the cultured fibroblasts, white blood cells and the hybrids are probably due to lactate dehydrogenase activity, indicating that the GPT-LDH linkages were spurious.

Connective stability of complex ecosystems

In 1970, Garner and Ashby[1] asked an important question: "If a large system is assembled (connected) at random, or has grown haphazardly, should we expect it to be stable or unstable?" They showed on a linear model that probability of stability generally decreases with the increase of the degree of connectedness among the parts of the system. This fact was confirmed by May[2] in a study of large systems in the ecological context.

Here I now report that a wide class of linear and non-linear time-varying large systems have been identified[3,4], which are stable in spite of changes in the degree of connectedness among the parts (subsystems) of the system. A large system is considered connectively stable if it is stable (in the sense of Liapunov) for any degree of connectedness among the subsystems. The connective property of stability can be established in the systems with competitive equilibrium[5], which appear as useful models in such diverse fields as biology[6] and the arms race[7], economics[5,8] and transistor circuits[9].

The development of the connective stability concept can be best illustrated on the linear model used in (refs 1 and 2):

$$\frac{d\mathbf{x}}{dt}=A\mathbf{x}$$

where $\mathbf{x}=<x_1\ x_2\ \ldots\ x_n>$ is an n vector and $A=(a_{ij})$ is an $n\times n$ constant matrix. I assume that A has negative diagonal elements[1], and non-negative off-diagonal elements, that is

$$a_{ij}\ \begin{cases}<0\ , & i=j\\ \geqslant 0\ , & i\neq j\end{cases}$$

The above system is stable if (and only if) the matrix A satisfies the Hicks conditions:

$$a_{11}<0,\ \begin{vmatrix}a_{11} & a_{12}\\ a_{21} & a_{22}\end{vmatrix}>0,\ \ldots,\ (-1)^n\begin{vmatrix}a_{11} & a_{12} & \ldots & a_{1n}\\ a_{21} & a_{22} & \ldots & a_{2n}\\ \ldots & \ldots & \ldots & \ldots\\ a_{n1} & a_{n2} & \ldots & a_{nn}\end{vmatrix}>0$$

I allow off-diagonal elements a_{ij} to be time-varying, and replace them with $e_{ij}a_{ij}$, where $e_{ij}=e_{ij}(t)$ are arbitrary functions such that

$$0\leqslant e_{ij}(t)\leqslant 1$$

Therefore, the elements $e_{ij}(t)$ of the $n\times n$ interconnection matrix $E=(e_{ij})$ measure the coupling from x_i to x_j and represent disconnection when $e_{ij}(t)=0$ at any time t. It has been shown[4,8] that, under Hicks conditions, stability of the system is invariant to changes in any (and all) $e_{ij}(t)$ and that the system is connectively stable.

In an ecological system, $\mathbf{x}$ is the vector of the populations x_i and the elements a_{ij} of the matrix A represent the effect of the jth species on the ith species in the neighbourhood of the equilibrium. Non-negativity of the off-diagonal elements $a_{ij}(i\neq j)$ implies (gross) symbiotic interactions among species. Negativity of the diagonal a_{ii}s means that each species is density dependent or 'stabilized'[2]. Both restrictions on the sign of a_{ij}s can be removed at the expense of more refined analysis. By applying the Hicks conditions to the McKenzie's diagonal form of A, the off-diagonal a_{ij}s can have arbitrary signs and connective stability of the ecosystem with mixed (competitive – predator – symbiotic – saprophytic) interactions among species can still be established. The restriction $a_{ii}<0$ can be removed by considering species in the stable 'blocks' (subsystems) and using the decomposition–aggregation methods[3,4,8] to conclude stability of the overall system by Hicks conditions. The decomposition–aggregation analysis can take advantage of special structural 'block' properties of ecosystems[2]. Furthermore, it is possible to demonstrate[8] wide tolerances to nonlinearities in the interactions of stable ecosystems reflected by non-linear elements $a_{ij}=a_{ij}(t,\ \mathbf{x})$ of the system matrix $A=A(t,\ \mathbf{x})$.

By increasing the magnitude of the off-diagonal elements a_{ij} and thus the interaction complexity of the ecosystem, the Hicks conditions are eventually violated. Since the conditions are both necessary and sufficient for stability, by reaching the critical values of a_{ij}s as determined by the Hicks inequalities, a sharp transition from stability to instability takes place. Therefore, there is an analytical basis[3,4,8] for verification of the important Garner–Ashby conjecture[1] and the equally significant May's experiment[2].

The recursive nature of the Hicks conditions suggests that individual parts of the system can be decomposed from each other and again composed together randomly in various ways without affecting stability. It should be noted, however, that Hicks conditions are valid only for the constant matrix A. Kamke's comparison principle and vector Liapunov functions from the theory of differential inequalities[10] are needed to extend the validity of Hicks conditions to matrices with time varying elements and to give a rigorous proof[4,8] of this intuitive result.

Palatability dynamics of cardenolides in the monarch butterfly

The adaptive strategy of sequestering cardiac glycosides from milkweed plants (Asclepiadaceae and Apocynaceae) has evolved in several taxa of insects[1]. Since these cardenolides elicit vomiting following ingestion, birds learn to avoid the insects on sight after one or more emetic experiences[2]. By a specific assay, we found a spectrum of cardenolide concentrations in adult monarch butterflies (*Danaus plexippus* L., Danainae) collected during the autumnal migration from four areas in eastern North America[3]. In this communication we compare Atlantic with Pacific Coast monarch populations and explore quantitative relationships between cardenolide concentrations and palatability spectra. The latter were measured by our blue jay (*Cyanocitta cristata bromia* Oberholser, Corvidae) emetic dose fifty (ED_{50}) test[4].

Migrating East Coast butterflies were netted in September 1971 in the floodplain of the Connecticut River in Northampton and Hockanum, Massachusetts. Those from the West Coast came from three overwintering colonies in California during November 1971 at Muir Beach, Natural Bridges State Park at Santa Cruz, and at the Academy of Music at Santa Barbara. All butterflies were frozen until oven dried and individually ground for analysis as before[3]. Cardenolide concentrations were measured from February to June 1972. Because there were no significant concentration differences between the California populations, they were combined for statistical analyses.

The spectrophotometric assay[3] was modified as follows: (*a*) a correction in the alignment of the visible light source of the Perkin-Elmer 402 spectrophotometer was made; (*b*) absorbances were read at the peak (626 nm); (*c*) a tendency for opalescence[5] was eliminated by changing the aqueous NaOH solution to 50% EtOH : 50% H_2O. These modifications resulted, respectively, in corrections of 1.08, 1.18 and 1.11, to give a combined correction factor of 1.42. As previously, the *F* peak (536 nm) of a holmium oxide filter was used to monitor machine performance ($n=83$; $\bar{X}$ absorbance $=0.377$; s.d. $=0.003$).

ED_{50} tests were done between March 1972 and February 1973 on blue jays trapped in Hampshire County, Massachusetts between December 1971 and February 1973. They were stored for various times in an outside aviary or inside in a 12 h light: 12 h dark regime. Birds given Massachusetts butterfly material were force fed once. Thirty-three birds given the California 0.250–0.279 and 0.320–0.399 subsample material (Table 2) had been force fed once, at least 5 weeks previously. The mean weight of the 226 birds was 84.25 g ($s^2=41.83$).

After determining cardenolide concentrations in 351 California and 355 Massachusetts butterflies (Table 1, Fig. 1), we combined the residual dry powders of both sexes into nine concentration range subsamples for California and eleven subsamples for Massachusetts (Table 2); as all residual powders were used, larger butterflies contributed more than smaller ones. After mixing, we measured the absorbance per 0.1 g of each subsample.

We then determined the ED_{50} values for most subsamples (Table 2). The lower concentration groups for both coasts either were not emetic or were subemetic so that these ED_{50} values could not be determined. The ED_{50} and subsample absorbance values were run in regression analyses by the method of least squares[7] to fit the exponential equation $y=ax^c$, giving high correlation coefficients (Table 3*D*). Because of the exponential relationship in both samples, the mean values and 95% confidence limits are plotted logarithmically together with regression lines (Fig. 2).

Concentrations are summarised in Tables 1 and 2 and in Fig. 1, which also shows the distribution of total cardiac glycoside per butterfly, obtained as the product of individual absorbance × dry weight. The histograms for the Massachusetts butterflies confirm the earlier study[3] and are essentially normal distributions showing continuous variation in cardenolide content. More than 98% of the Massachusetts monarchs contained substantial amounts of cardenolide. The population of California monarchs, however, was effectively dimorphic, with 47% of the individuals containing little to immeasurable amounts.

As Fig. 1 and Table 1*A* show, California butterflies had a much lower mean cardenolide content than the Massachusetts butterflies, even when values were recalculated after excluding all butterflies with absorbances of less than 0.100 per 0.1 g (Table 1*B*). With this group excluded, the variance of the cardenolide content in both sexes was three to four times greater in the Massachusetts butterflies. In both samples females had higher concentrations than males. The two-way analyses of variance[8] indicate that both geographic and sexual differences in concentration were highly significant.

The size (right forewing length, measured with calipers from base to apex) and dry weight of the butterflies were highly correlated (Table 3*B*)[9]. The males were heavier as well as larger than the females on both coasts (Table 1*C* and *D*). California butterflies, however, although significantly smaller than their Massachusetts counterparts, were substantially heavier, no doubt because of a higher fat content (observed during grinding). Moreover, California butterflies showed greater discrepancy between the sexes for both weight and size (interactions). The differences in cardenolide content between the sexes, exaggerated in the California butterflies (Table 1*A* and *B*), support the idea[3] that there is a significant physiological

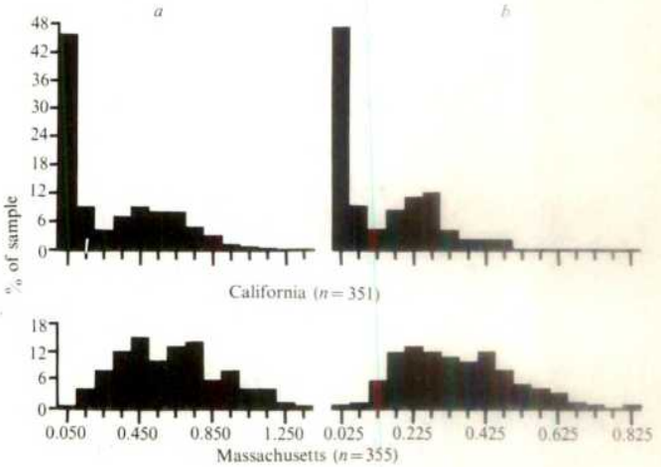

Fig. 1 Variation in cardiac gycoside content of monarch butterflies from California and Massachusetts (data are in Table 1). *a*, Total cardiac glycoside (absorbance per butterfly); *b*, cardiac glycoside concentration (absorbance per 0.1 g butterfly). The West Coast monarchs are bimodal, with nearly half containing little to immeasurable amounts of cardiac glycosides. The East Coast monarchs are unimodal and have a substantially higher mean cardenolide content. An extract of 0.1 g of butterfly in 5 ml of alcohol which gives an absorbance of 0.200 by our standard method is equivalent to a 3.16×10^{-5} M solution of digitoxin, or 241 μg per 0.2 g butterfly.

†† No birds vomited; dosed at 0.287 and 0.350 g.
‡‡ One bird dosed at 0.287 g vomited; two each dosed at 0.287, 0.350 and 0.428 g did not.
§§ Two birds dosed at 0.287 g did not vomit; at 0.350 g two did and one did not; at 0.428 g one did and two did not.
¶¶ Three birds dosed at 0.368 g did not vomit; at 0.407 g, three did and two did not; one bird each at 0.449 and 0.496 g did not vomit.

cost to sequestering these compounds.

The relationships of cardenolide concentrations and ED_{50} values are shown in Fig. 2 and Table 2. Although there seems to be an upper limit for both the California and Massachusetts butterflies, generally the higher the concentration of cardenolide, the lower the dose needed for emesis. However, at all emetic concentrations, the California monarchs were more emetic than their Massachusetts counterparts. Within the range of overlapping absorbances, at 0.250 and 0.475, the Massachusetts ED_{50} values were, respectively, 0.264 g and 0.162 g, compared with California ED_{50} values, respectively, of 0.057 g and 0.025 g. In other words, within this absorbance range the California monarchs were at least 4.6 to 6.5 times as emetic. This no doubt mirrors the separate *Asclepias* floras on the East and West coasts[10], several species of which are known larval food plants of the monarch[11].

Both dry weight and size were negatively correlated with cardiac glycoside concentration in the Massachusetts females, and significance was approached for the Massachusetts males (Table 3*A* and *C*). In contrast, neither sex in California showed these correlations. In order for the Massachusetts butterflies to be sufficiently emetic, they must incorporate

Table 3 Summary of linear regression analyses of cardenolide concentration (absorbance per 0.1 g powdered butterfly), dry weight (g), and right right forewing length (cm)

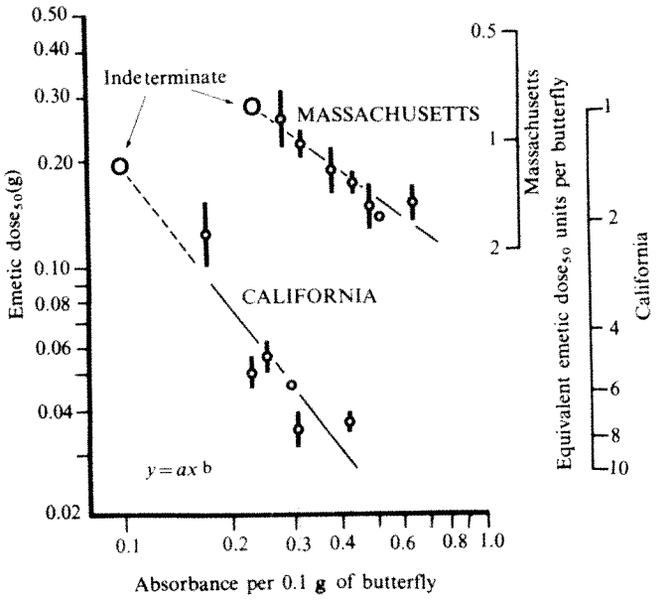

Fig. 2 Relationship of cardiac glycoside concentrations and ED_{50} values (data are in Table 2). The lines extending from the small open circles are the 95% confidence limits of the means; the dotted lines represent indeterminate to nonemetic concentrations. Emetic dose is inversely related to cardiac glycoside concentrations, thereby proving that the palatability spectrum in these wild monarch butterflies is causally related to a spectrum in cardenolide concentration. Cardenolides in the California butterflies, however, are far more emetic than those in the Massachusetts butterflies, no doubt reflecting the completely distinct *Asclepias* species on the two coasts from which the wild larvae sequester the poisons. The ranges in equivalent emetic dose 50 U per blue jay predator per butterfly are shown on the right side of the graph.

more cardiac glycoside than the California butterflies and these higher concentrations may be physiologically detrimental.

In terms of blue jay ED_{50} units, the Massachusetts butterflies ranged from an estimated maximum of 2.0 to less than 0.9, whereas the more toxic California butterflies ranged from 10.6 to 2.8. We did not resolve the number of ED_{50} units below these minima. There is, however, a concentration threshold below which the butterflies are effectively not emetic in terms of the numbers capable of being ingested per bird per unit time. For the California sample, this threshold is certainly not less than an absorbance of 0.050, so that at least 47% of the population is effectively palatable. A small percentage of the population (perhaps 5–10%) contains less than one emetic unit and is therefore of intermediate palatability, while the remaining 43–48% is unsuitable as food. For the Massachusetts sample, the threshold is not as clear-cut, but is probably near an absorbance of 0.150. Thus only about 10% of the Massachusetts population is effectively palatable, with a larger group of intermediate palatability (about 35%), leaving approximately 55% of the population with one to two ED_{50} units.

The mean absorbance per butterfly in Massachusetts reported[3] in 1970 (0.198), when corrected (0.281), was 15% lower than found in 1971, ($t = 3.42$, d.f. $= 475$, $P < 0.001$). However, the corrected absorbance values of one ED_{50} unit for the 2 yr are very similar: 0.327 for 1970 and 0.320 for 1971. In other words, the basic emetic properties per unit of absorbance remained virtually the same, but the mean concentration changed, probably because of a difference in environmental factors affecting cardiac glycoside production in the wild milkweeds during the 2 yr.

The fact that California and Massachusetts populations contain both palatable and unpalatable butterflies verifies the heretofore largely theoretical category of mimicry known as automimicry[12,13]. In this type of mimicry, which is mathematically analgous to a perfect Batesian mimicry system, the palatable individuals of the species derive mimetic protection from the unpalatable portion of the same population from which they cannot be visually distinguished. Automimicry theory predicts that the more noxious the unpalatable individuals are, the higher can be the proportion of palatables in the population. The greater percentage of completely palatable butterflies in the much more noxious California population compared with the Massachusetts population verifies this prediction. Moreover, the high degree of protection that must result from the very emetic California butterflies probably made possible the evolution of the spectacular overwintering clusters which are found on the California coast but not in the East.

The assumption that wild Danaine butterflies are uniformly unpalatable has played a key roll in the development of mimicry theory. This assumption can no longer be made, however, either in attempts to interpret older experiments[14] or in future work. Our study makes it clear that unpalatability is a dynamic situation. We must also question whether all Danaine species are equally adept at sequestering cardenolides, as well as whether they are equally able to eat the various poisonous to nonpoisonous milkweed species available to them. Because of the dynamics of palatability, certain of the inconsistencies in the mimicry literature, such as the colour polymorphism found in some populations of supposedly unpalatable butterfly species[15], now seem amenable to analysis. An interesting case is the widespread African *Danaus chrysippus* L. which is polymorphic in some parts of its range and monomorphic in others[16]. Where monomorphic, a substantial portion of the population is probably unpalatable. But in other areas, *D. chrysippus* may be effectively palatable and a polymorphic Batesian mimic.

The distinct differences in emetic properties of the cardenolides found in the Massachusetts and California butterflies suggests that more *Asclepias* species might profitably be investigated to discover new cardenolides which retain their useful attributes as heart drugs, but which have less noxious emetic side effects[17,18].

The research was supported by grants from the US National Science Foundation. We thank Susan C. Glazier who coordinated the bird experiments, Homer Bessonette for technical help and Dr James Seiber and Carolyn Roeske for valuable comments.

Genetic selection of winner and loser rats in a competitive situation

GENETIC selection of behavioural characteristics has been observed, among others, in the Maudsley, Roman, and Tryon strain of rats[1]. Here we describe an experiment designed to test the hypothesis that rats could be selectively bred to win or lose in a food competition situation of the type reported by Lindzey *et al.*[2] with mice and later used by other authors with rats[3–8].

The apparatus is described in detail elsewhere[5]. Briefly, it consisted of a straight wood runway 100 cm long, connected at the extremities with two identical open-topped chambers; a guillotine door bisected the runway. The animals had food withheld for 20–22 h and were trained individually every 48 h to traverse the runway to be rewarded with food. They were then subjected to the contest situation, in which two rats were simultaneously introduced into the opposite sides of the apparatus. As the rats met in the middle of the runway, one pushed the other and gained the reward.

The offspring of three randomly selected couples of Wistar rats from our own colony, mantained by random breeding, were subjected to the competitive situation when about 80 d old. A stable hierarchy of winners and losers was obtained among seven females and seven males. The two male rats which consistently won were bred with the two females that were winners from their hierarchy. Similarly, the two loser rats of the female and male hierarchy were also bred. The offspring (F1) consisted of 15 rats which were descendants of winner couples (DW) and 14 rats which were descendants of loser couples (DL). At 80 d of age, competitive hierarchies were established independently for DW males, DW females, DL males and DL females. The two DW male rats which occupied the top of the hierarchy were mated with the two DW female rats which also occupied the first and the second positions. Similarly, the two DL males at the bottom of their hierarchy were mated with the two DL females which occupied the last two positions. Only one female and one male were put together for mating.

F2, consisting of 15 DL and 11 DW were tested against random-bred controls, using a fixed pair procedure. Each pair was made up by a DW or DL rat and a random-bred control of the same sex and age. Each pair was subjected to three experimental sessions consisting of five contests each. After that, the rats were selected for mating according to their number of wins (DW that won at least 13 out of the 15 contests and DL that lost at least 13 out of the 15 contests). F3 (31 DW and 31 DL) and F4 (32 DW and 32 DL), were subjected to the same procedure as F2. In the three generations (F2, F3 and F4) tested against randombred controls, the DW rats won about 75% of the contests while the DL rats lost nearly 80% of the contests. Throughout the generations, mating brothers and sisters was avoided when possible. At the F1 and F2 about 50% of the couples which were mated were brother and sisters while this dropped to about 10% in the following generations.

In F5, 60 pairs were formed, each consisting of a DW and a DL rat of similar weight. Thirty-seven pairs were females and the remaining 23 males. Each pair, deprived of food for about 22 h, was tested using the fixed pair procedure. Three experimental sessions were run, consisting of five contests each. The results (Fig. 1) show that DW rats consistently won more than 80% of the 15 contests. In all generations, records of weights were kept and correlations between weight and number of wins were calculated. No significant correlations were found.

These data indicate that genetic selection occurred. DW and DL rats probably have different behavioural or physiological characteristics, which are yet to be detected, that led them either to win or lose in the straight runway. The possibility that the results obtained were not due to genetic selection but to an influence of the mothers during weaning was excluded, as in the F4 and in the F5 generation, all rats were reared by foster mothers.

How winning and losing in the straight runway correlates with other competitive situations remains to be investigated.

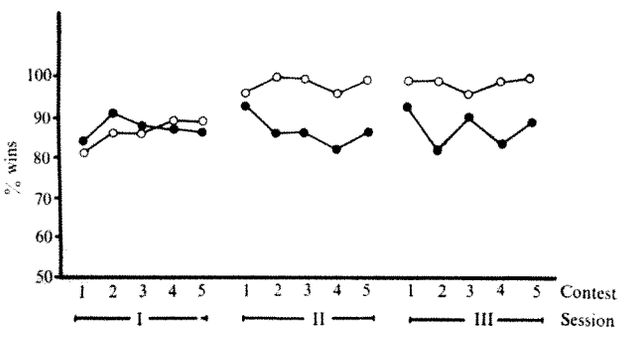

FIG. 1 Percentage of wins obtained by 23 DW males (●) and 37 DW females (○) when competing in a straight runway against 23 DL males and 37 DL females, respectively. The difference between the number of victories obtained and the casual level of 50% was significant in every contest. The statistical analysis was performed for females using the binomial test for large samples ($P \leq 0.001$) and using the binomial test for small samples for males ($P \leq 0.002$).

Infectious particles in a marine ciliate

INFECTIOUS, self-reproducing particles of unknown origin have been demonstrated in various tissues and cells[1,2], notably fresh water protozoa[3], but not in marine protozoa. Advances in the development of culture media for marine ciliates[4] and the need for simple model systems for biochemical study of intracytoplasmic particles have led us to survey marine protozoa. Of 104 isolates made from twenty-one seawater samples taken from tidal pools and brackish backwaters along the South Florida coast, twenty-six were cultivated axenically as described before[4]. Of these, four contained in their cytoplasm infectious, self-reproducing particles, which we have termed 'xenosomes' (*xenos*, alien; *soma*, body).

The xenosomes were found in aceto-orcein-stained preparations[4] under the phase microscope (Fig. 1*a*). They seemed to be distributed randomly throughout the cytoplasm. We

have maintained one xenosome-bearing stock, a small hymenostome ciliate identified as *Parauronema acutum* 110-3, for more than 2 yr, subcultured weekly, without loss of particles. The ciliates were maintained axenically in M medium[4] modified to contain 500 μg ml^{-1} asolectin as the sole source of lipid, at 22°C in the dark. From 10 l of late logarithmic phase culture containing approximately 10^6 animals ml^{-1}, we recovered as many as 8.0×10^{11} highly purified particles per attempt (Fig. 1*d*). The method of isolation and purification of the particles was essentially the same as that used with the mu and pi symbionts of *Paramecium aurelia*[5]. Xenosomes appear as rod-shaped particles, approximately 0.3 μm wide and 1.0 μm long. They occur exclusively in the cytoplasm in numbers reaching 300 per protozoon. When released from the protozoa (ruptured by gentle pressure of a glass coverslip) the particles can be seen spinning (propellor-like) and darting rapidly, suggesting the presence of a motile apparatus, perhaps flagella. Xenosomes are Gram negative and appear to divide within the cytoplasm by transverse fission, as evidenced by a furrow, seen in some particles, in a plane perpendicular to their long axis. The appearance of the particles in the electron microscope (*in situ*) suggests that they are bounded by a double-track membrane (Fig. 1*c*). Dispersed throughout the internal contents of the particle is a network of fibrous strands, which disappears after treatment with DNase and, presumably, consists of DNA. Attempts to culture the particles outside the host in media similar to that used for the ciliates themselves have not been successful. Nor has it been possible to grow particles in media supplemented with biological materials and growth factors.

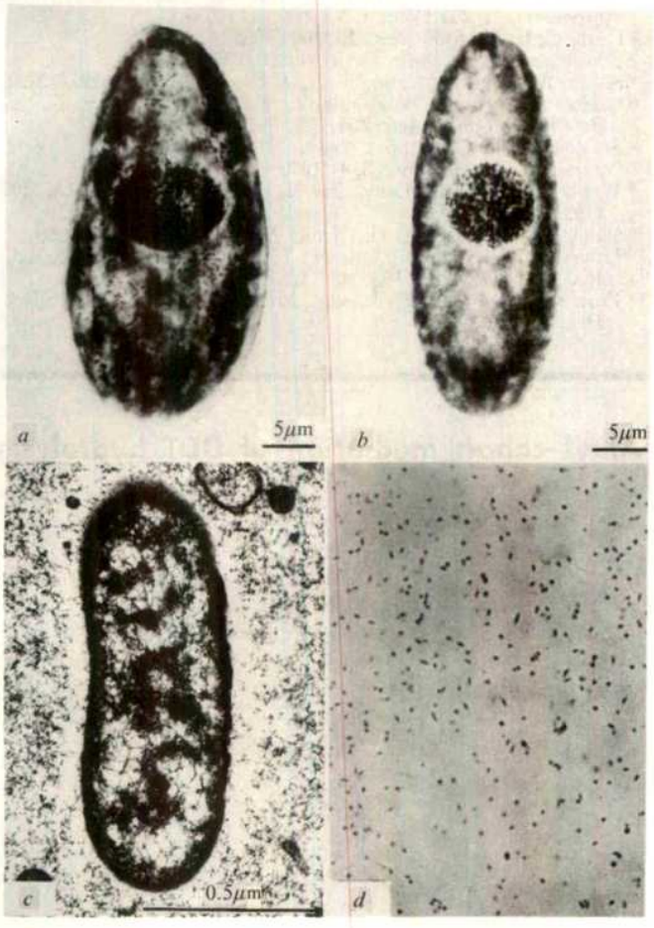

FIG. 1 Phase micrographs of xenosome-bearing (*a*) and xenosome-free (*b*) *Parauronema acutum* stained with aceto-orcein dye. (*c*), Electron micrograph of a xenosome *in situ*. Specimens were fixed in 1.33% OsO_4 buffered with 0.2 M γ-collidine, *p*H 7.4 prepared in seawater of density = 1.015 g cm^{-3} for 30 min at 0°C. Ciliates were left in buffer overnight at 0°C, dehydrated through an alcohol series and embedded in Araldite. Ultrathin sections were cut with a glass knife, doubly stained with alcohol-uranyl acetate and lead acetate and examined in a Phillips EM 300 electron microscope. *d*, Phase micrograph of isolated and purified xenosomes, unstained (×570).

TABLE 1 Comparison of infectivity of whole culture blendates (cell-free) with filtrates of xenosome-bearing *P. acutum* 110-3

Sample tested	Sample dilution: As is	1:2	1:4	1:8	1:16
Whole culture, blended and filtered	76	41	18	0	1
Filtrate only, no blending	80	39	17	3	0
Filtrate only, blended	75	52	28	7	0

Figures represent percentage of animals infected.

Cultures of xenosome-bearing *P. acutum* 110-3 in the exponential phase of growth (population density, $0.5 \times 10^6 - 1.0 \times 10^6$ animals ml^{-1}) were either blended in a sterile Waring blendor to more than 95% cell breakage and filtered through a sterile Millipore filter (8 μm pores) to remove unbroken cells, or filtered directly without blending. Samples of 0.1 ml of the filtrates, or dilutions thereof, were added to 0.9 ml each of fresh modified M culture medium contained in the wells of nine-spot depression slides, inoculated with about 200 particle-free animals, and incubated at 22°C in the dark in humidifying chambers for 7–10d. About 5 μl of the cell suspension from each depression was then placed on a glass slide, exposed to osmium vapours (2% (w/v) OsO_4 in distilled water) for about 5 s and allowed to dry at room temperature. A small drop of aceto-orcein dye was added, followed by a coverslip, and the animals were viewed under oil immersion using phase optics in the Leitz microscope. Fifty animals from each depression were observed and scored for the presence of particles. The number of animals containing particles from triplicate depression slide cultures were averaged and the data expressed as percentage of animals infected. A filtered sample of the culture, blended for the same time as the whole culture, was included as a control.

Purified particle preparations were fractionated by the Schneider procedure[6] and the nucleic acids were extracted from the dry, de-fatted residues with hot trichloroacetic acid (TCA). The extract was analysed for DNA by the diphenylamine procedure[7] or by the method of Webb and Levy[8] and for RNA by the orcinol procedure[9]. Protein was determined by solubilising the TCA-extracted residue in 0.1 N NaOH and assaying the extract by the Lowry procedure[10]. The DNA, RNA and protein content of the isolated particles (pg per particle ($\pm$ s.d.)) was 0.008 $\pm$ 0.002; 0.031 $\pm$ 0.007; and 0.041 $\pm$ 0.007 respectively. The data represent average values of nine duplicate determinations of seven preparations.

When penicillin, tetracycline or chloramphenicol were added to the culture medium at the time of inoculation, the particles within the cells were destroyed and lost irreversibly from the cytoplasm. (Optimum concentrations that eliminated particles from the cytoplasm but did not significantly affect growth or division were 50 U ml^{-1} for pencillin, 0.5 μg ml^{-1} for tetracycline and 0.25 μg ml^{-1} for chloramphenicol.) Cycloheximide, neomycin sulphate and streptomycin had no such selective effect. Xenosomes *in situ* were also destroyed by irradiation with an electron beam (Fig. 2*a*): the effective dose (ED_{50}) was about 30,000 rad, comparable with values reported for X-irradiation of certain bacteria and members of the Mycoplasma[11]. The ED_{50} for the protozoon itself was approximately 260,000 rad. Thus, xenosomes could be removed from the cytoplasm of the ciliates by treatment with the electron beam using doses of about 200,000 rad (see graph in Fig. 2*a*).

The infectious nature of the particles was demonstrated by adding aliquots of cell-free blendates or filtrates of xenosome-bearing cultures to particle-free animals and observing the uptake of the particles into the cytoplasm. The infective agent readily passed through Millipore filters with pores 8 μm

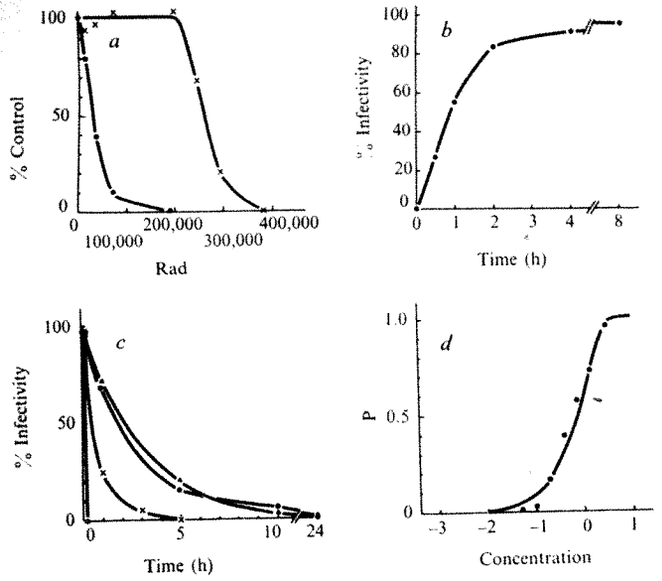

FIG. 2 *a*, Selective effect of electron beam irradiation on xenosomes *in situ*. *Xenosome*-bearing *P. acutum* 110-3 was inoculated into 5 ml of fresh medium in sterile 30-ml tissue culture flasks (No. 3012, Falcon) at a cell density of 10,000 ml^{-1}. The cell suspension was 2 mm deep. Flasks were irradiated in a CLINAC 6 MeV linear accelerator (Varian Associates) with an output of 3.5 MeV at 10,000 rad min^{-1} for doses up to 100,000 rad and 100,000 rad min^{-1} for larger doses. Flasks were then incubated for 7 d at 22° as in the dark. Both protozoon and particle populations were estimated as described previously[5]. Population densities of non-irradiated protozoons averaged 2.3 × 10^6 ml^{-1}; the number of xenosomes per protozoon was estimated at 204 ± 25 (s.d.). Thus, the 'population' of xenosomes calculated per ml of culture was 4.7 × 10^8. x, Protozoan; ●, xenosomes. *b*, Release of infectious agent into ambient culture fluid. Exponential phase xenosome-bearing animals cultured in M medium were washed free of exogenous particles by centrifugation three times at 600 *g* for 1 min each, suspended in M medium at a cell density of 500,000 ml^{-1} and left at 22°C in the dark. Samples were removed at intervals, filtered (Millipore, 8 μm pores) to remove the cells, and filtrates were assayed for infectivity as described in Table 1. *c*, Stability of infectious agent to temperature. Filtrates of exponential phase xenosome-bearing animals cultured in M medium were left at various temperatures. Samples were removed at intervals, brought rapidly to 22°C and assayed for infectivity (see Table 1) ○, 65°C; ×, 37°C; ●, 22°C; ▲, 4°C. *d*, Experimental frequency of positive response (infectivity) to various concentrations of xenosomes in filtrates of xenosome-bearing *P. acutum*. Abscissa: logarithm of concentration (empirical scale). Ordinate: *P*, frequency of infection. Each point represents the average value of four experiments. The solid line was the curve derived from the expression $P_{r,s} = 1 - e^{-s}$ where P_r is the probability of having at least one infective particle per protozoon and *s* is the average number of particles per sample. Infectivity was determined as described in Table 1.

in diameter, but not when the pores were 0.45 μm or less in diameter. We found no significant quantitative difference when whole filtered blendates were compared with cell-free culture filtrates for infectious activity (Table 1). This suggests that infectivity is associated with a particulate agent released from the protozoon into the culture medium. Figure 2*b* shows the release of the infective agent into the ambient culture fluid from particle-bearers washed free of exogenous particles. The infectious agent was relatively unstable to temperature (Fig. 2*c*). Infectious activity was lost almost immediately at 65°C; about half the infectious activity remained after 1 h at 37°C and after 2 h at 22°C or 4°C. Sonication for periods as brief as 20 s completely inactivated particles present in cell-free culture filtrates. Attempts to stabilise the infectious agent by varying conditions of ionic strength, osmotic pressure and *p*H have been unsuccessful. Statistical analysis of the mode of action of the infectious agent present in culture filtrates suggests that a single particle can infect a susceptible particle-free animal (Fig. 2*d*).

Although host range studies were limited by the lack of well-characterised strains of marine ciliates, we have found that the xenosomes of this strain can infect three other particle-free stocks of *Parauronema acutum*, but not *Uronema nigricans* or the related *Parauronema virginianum*.

We thank Arthur C. Borror, University of New Hampshire for identifying *Parauronema acutum*, G. Musil for the phase and electron micrographs and M. Feldman for the radiation study with the electron beam. The work was supported in part by the US National Science Foundation.

Alkyl–cobalt mediation of DDT hydrolysis

A POSSIBLE role for vitamin B_{12} in the detoxification of polyhalogenated hydrocarbon pesticides such as DDT has occasionally been postulated (ref 1 and references therein), and DDT has been shown to inhibit bacterial B_{12}-dependent methanogenesis[2]. Although reduced cobalamins and cobaloximes will react with simpler species such as polyhalomethanes[3,4], no adduct between DDT or related compounds and cobalt has previously been observed[2]. It has been suggested that alkyl–cobalt complexes of the ligand CR (Fig. 1)

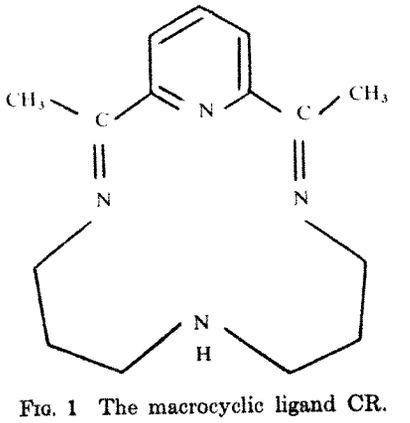

FIG. 1 The macrocyclic ligand CR.

have some chemical similarities to B_{12} (ref. 5) and zinc complexes of CR have yielded results relevant to carbonic anhydrase[6]. We report the use of cobalt–CR to mediate the hydrolysis of DDT, the isolation of an alkyl–cobalt derivative of a hydrolysis product of DDT, and the formation of di(*p*-chlorophenyl)ketone from this compound.

The Co(II) complex of CR was prepared in aqueous ethanol by the standard template method[7], and reduced *in situ* to the nucleophilic Co(I) species using borohydride at *p*H 9. This was allowed to react under nitrogen with pure *p, p'*-DDT, and the solution warmed to 40° C and stirred for 12 h in the dark. A deep red, light-sensitive solution resulted and addition of PF_6^- or ClO_4^- produced a red, tarry product. This was very difficult to purify but a small quantity of the ClO_4^- salt was isolated as a clean, maroon powder by repeated reprecipitation from ethanol/ether.

The infrared spectrum of this compound has an intense band around 1,100 cm^{-1}, confirming the presence of ClO_4^-. A broad area above 3,200 cm^{-1} and around the Nujol absorption at 2,900 cm^{-1} is attributable to a carboxylic acid group hydrogen bonding with water. The region 1,550–1,675 cm^{-1} is dominated by the C=C and C=N vibrations of the aromatic rings and these could well mask the C=O stretching vibration if this group displays some resonant single-bond character. The presence of ionic chloride in the compound was demonstrated by silver nitrate titration and the resulting solution was left in sunlight for a few days. Extraction of the solution with toluene yielded a white powder—shown to be pure by thin-layer chromatography—with a mass spectrum identical to that of an authentic sample of di(*p*-chlorophenyl)ketone. These results lead us to suggest that the complex is as shown in Fig. 2; this is supported by microanalysis (required percentages for $CoC_{29}H_{35}N_4O_9Cl_4$: C, 45.3; H, 4.6; N, 7.3; total Cl, 18.5: percentages found: C, 44.8; H, 4.5; N, 7.7; total Cl 18.1) and by mass spectrometry. Thermolysis of the compound on the mass spectrometer probe at 200° C produced many fragments but, considering only those displaying peaks at the highest values of *m/e*, groups are observed at *m/e* = 248, 250, 252 (intensities 9:6:1) and 235, 237, 239 (9:6:1). The isotopic distribution of ^{35}Cl and ^{37}Cl implies that these peaks are due to species each containing two chlorine atoms. Since the aromatic chlorines will be stable under the reaction conditions used, in contrast to the aliphatic chlorines, we assign these peaks to $(p\text{-}ClC_6H_4)_2C_2H_2^+$ and $(p\text{-}ClC_6H_4)_2CH^+$. The latter is expected from cobalt–carbon bond cleavage and loss of CO_2, and peaks attributable to $(p\text{-}ClC_6H_4)_2CH.C(OH)_2^+$ are present in the region *m/e* 281–285 but the relative intensities are obscured by the presence of other fragments. It has been pointed out to us that the former set of peaks may be due to hydrogen transfer from the CR ligand during thermolysis.

The formation of the isolated compound from Co(I)CR and DDT may be readily rationalised. Nucleophilic attack by Co(I) will displace Cl^- and the resulting complex can then eliminate H^+ and Co(I) to form 1,1-di(*p*-ClC_6H_4)-2,2-dichloroethylene; further attack on Cl by Co(I) and hydrolysis of the chlorines on C2 gives the aldehyde hydrate which is easily oxidised to the acid during workup. The type of reactions involved here have been fully documented by Schrauzer[4,8]. The production of di(*p*-chlorophenyl)ketone is explained by photolysis of the cobalt–carbon bond to form a radical, which in aqueous solution gives rise to the α-hydroxy-carboxylic acid. In the presence of Ag(I) and a radical species such as Co(II) or O_2 this will readily decarboxylate to the ketone (Fig. 3) (J. Staunton, personal communication).

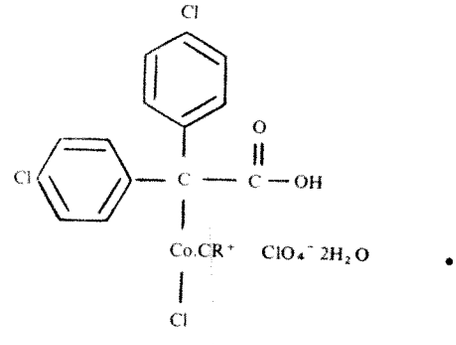

FIG. 2 Suggested structure of the isolated alkyl-cobalt intermediate.

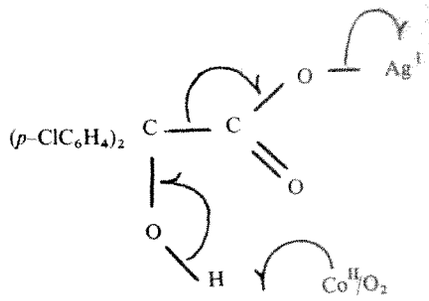

FIG. 3 Suggested decarboxylation mechanism.

These results indicate that the involvement of alkyl–cobalt species in the hydrolytic detoxification of DDT is chemically feasible. They also show that hydrolysis and partial degradation of DDT by this route requires far less vigorous conditions than the strong base and oxidising agents usually used to bring about these reactions. There are evidently many possible reaction pathways for the dechlorination of DDT in complex biological systems such as anaerobic sewage sludge[9]. The presence of microorganisms in these wastes means that B_{12}-mediated routes are available—several such routes have also been implicated in the biological fixation of mercury[10,11]—and it is thus of great interest to note that di(*p*-chlorophenyl)ketone is formed among other products from DDT in sewage sludge[12]. The possible involvement of B_{12} in the formation of this compound, rather than its being a degradation produce of di(*p*-chlorophenyl)acetonitrile[12], is open to consideration.

We thank the staff of the undergraduate laboratories for samples, the staff of the microanalytical department, and the Science Research Council for a grant to D.A.S.

GENERAL

Genetics and the development of social attitudes

WHATEVER the current norms might be with regard to public opinion about various issues, and whatever factors contribute to their change with time, attitudes are far from uniform. Eysenck[1] has shown how responses to a public opinion questionnaire could be resolved into two main factors: 'radicalism' (R) against 'conservatism' and 'toughmindedness' (T) against 'tendermindedness'. Individual differences in opinion are, to some degree, the social manifestation of individual differences in personality. Significant covariation has been detected between various measures of extraversion (E) and T. Wilson[2] has suggested personality correlates of R. Such relationships, together with available evidence for the genetic determination of personality differences (see, for example, ref. 3), justify a more penetrating analysis of the extent to which variation in opinion and personality share a common genetic basis.

We consider the causes of trait covariation within and between pairs of monozygotic (MZ) and dizygotic (DZ) twins. From the responses of 708 volunteer pairs of like-sexed twins to an 80-item Personality Inventory and to a 60-item Public Opinion Inventory, scores were derived on scales of psychoticism (P), extraversion (E), neuroticism (N), R and T, together with an emphasis (Em) score which indicated any tendency of subjects to adopt more extreme opinions. The questionnaires and the scoring keys used have been published elsewhere[1,4].

On the basis of replies to questions concerning childhood similarity, the twins were diagnosed as MZ or DZ (ref. 5). The pairs differed in their ages and in the time for which they had lived apart. Our analysis is based on the raw scores and the absence of an age correction will not severely affect the conclusions from a study which can only detect gross effects.

The MZ intrapair differences in personality were not related to the duration of separation, so we have pooled separated and unseparated twins. The composition of the sample by zygosity and sex is shown in Table 1, and it can be seen that it is not representative of zygosity or sex, although the twins are representative of the population with respect to variation for the traits in question. The data were summarised by the mean squares and mean products within and between pairs for every trait and group of twins.

Twin data alone are inadequate for a detailed genetic analysis, particularly when the twins were not properly separated[6], so the structure of our data limited us to tests of comparatively simple hypotheses. We had to accept estimates of components which may be biased and tests which are not very powerful.

We wished to test, and hoped to choose between, two hypotheses of equal rank about the causes of variation and covariation for our six scales of personality and attitude. The hypotheses are: (1) that all the observed trait variation and covariation is attributable either to differences between the environmental influences shared by members of the same pair (E_2), or to differences in the environmental influences specific to individuals within the family (E_1); and (2) that all the variation and covariation is attributable either to the cumulative and additive effects of many loci for which the population is polymorphic (D_R), or to specific (E_1) environmental influences. We refer to the first hypothsis as the 'simple environmental hypothesis' and the second as the 'simple genetic hypothesis'.

For a particular pair of traits, i and j, we can write expectations for the mean products, in terms of the genetic and environmental covariance components for that pair of traits.

TABLE 1 Composition of the sample of twins (number of pairs)

		Sex		Total
		Male	Female	
Zygosity	MZ	120	331	451
	DZ	59	198	257
Total		179	529	708

These components are D_{Rij}, E_{1ij} and E_{2ij}, and they have been defined in detail and the restrictions on their interpretation discussed elsewhere[1]. The expectations derived for both simple hypotheses are given in Table 2.

The coefficients of D_R are applicable to randomly mating populations. The slight assortative mating observed for personality variables is insufficient to cause a serious departure from these expectations, since the heritability of the traits is quite low. Insel[8] reported correlations between spouses for the Wilson Conservatism Scale, finding values between 0.59 and 0.66. If this correlation had a large genetic component, its effect in our case, would be inseparable from E_2 and would contribute to failure of our simple genetic model. It is possible to obtain weighted least squares estimates of the parameters of either model[7]. A detailed analysis suggested that the genetic and environmental parameters might be inconsistent over sexes. At the risk of introducing some redundancy into our model, therefore, we allowed different values for our estimates in the two sexes and subsequently compared them. There are 168 raw statistics altogether, and we fit 84 parameters, leaving 84 d.f. for testing either model.

When the simple environmental hypothesis was tested we found that the residual $\chi_{84}^2 = 167.31$ ($P < 10^{-6}$) so we concluded that a model invoking only environmental factors fails to provide an adequate description of the variation and covariation of the six traits. For the simple genetic hypothesis, we found that the residual chi square is smaller ($\chi_{84}^2 = 111.60$, $P \simeq 0.025$) and just significant. A model in which D_R E_1 and E_2 were fitted jointly gave a very satisfactory fit ($\chi_{42}^2 = 47.98$, $P \simeq 0.24$), suggesting that some E_2 parameters might be added to our simple genetic model. By this stage, however, there were many redundant parameters in the model and in the absence of any theory about which parameters could be deleted from the more complex model, we present the results of the simple genetic model, bearing in mind that some modification might still be appropriate (Table 3). The results were obtained by pooling estimates over sexes.

The estimates for the components of variance can be used to calculate heritabilities for the six traits from

$$\hat{h}t = \tfrac{1}{2}\hat{D}_R/(\tfrac{1}{2}\hat{D}_R + \hat{E}_1)$$

and provided we are justified in accepting our model, these estimates refer to the proportion of the population variance which is genetic in origin (Table 4).

The simple environmental model is insufficient to explain the observed variation and covariation of the traits in this study. We are, however, restricted by the structure of the data available. A larger or better designed study might identify common environmental influences in the departures from expectation which, in our study, appear as error. We

TABLE 2 Expectations of mean squares (mean products) on two simple models

Model	Expectation: Environmental		Genetic	
Parameter	E_{1ij}	E_{2ij}	D_{Rij}	E_{1ij}
Mean square/product				
Between MZ pairs	1	2	1	1
Within MZ pairs	1			1
Between DZ pairs	1	2	$\frac{3}{4}$	1
Within DZ pairs	1		$\frac{1}{4}$	1

¶ Significant at the 0.001 level.

can, however, be reasonably confident that some kind of genetic mechanism has to be invoked to account for the observations so far. That such a mechanism might involve the correlation of developmentally significant environmental factors with genetic variation should not be discounted. About half the variation between individuals for the six traits has a genetic basis (Table 4).

There are also some predictable significant covariance terms. Our study confirms the correlation between *E* and *T*, showing that it has a genetic, rather than an environmental basis, since only the D_R component is significant. There is also a significant genetic correlation between *P* and *Em*. This suggests that individuals who achieve high *P* scores share the strong conviction of being right, which is characteristic of some psychotic behaviour. The more significant tendency, for high *P* scores to be associated with 'toughmindedness' scores, is perhaps indicative of psychopathic tendencies which are known to be related genetically to psychosis and hence to *P* (ref. 9).

Although we claim to show some common basis for differences in personality and attitude, we stress that, for the scales in question, the greater part of the genetic and environmental variation is specific to particular traits. 'Radicalism' scores, for example, are totally independent of the measured personality variables, although they have significant associations with the other attitude measures.

Genotype–environmental interaction could inflate our estimates of both D_R and E_1. Some kinds of correlation between *G* and *E* may be discounted because the fit of the D_R, E_1, E_2 model implies that the total dispersions are homogeneous for the different kinds of twins. In many cases, however, genotype–environment correlation, if present, remains as a source of bias in our estimated genetic components.

Our model assumed that gene action is purely additive. Even without the complication of E_2 it would have been virtually impossible to identify any non-additive variation in our study. The bias in parameters estimated from twin studies in the presence of dominance is discussed elsewhere[7].

Extrapolation from these results to other populations and cultures is likely to be misleading because they are almost certain to differ with respect to the relative importance of different determinants of variation.

If we restrict ourselves to the British population and contemporary culture, we expect, on the basis of our simple genetic model, that attitudes in parents would be relatively poor predictors of attitudes in offspring. Parent–offspring correlations would be about $\frac{1}{2}ht$, given random mating, and thus to be roughly between 0.2 and 0.3. Many of the available familial correlations for attitudes (see for example, ref. 10) come from pre-war studies and show parent–child and sibling correlations which are much higher. The difference, if real, could reflect the consequences of cultural change during the last 30–40 yr. If individuality and mobility were not encouraged, common environmental (E_2) influences might play a significant part in maintaining the pattern of variation in attitude. In such a situation, parent–offspring correlations would resemble those for siblings and MZ twins. A culture which promotes individuality and mobility, however, may reveal a pattern of similariy between relatives which depends more obviously on genetic components and give greater significance to the environmental experiences which are unique to the individual, irrespective of his family environment. More recently, Insel[8] has obtained correlations between parents and offspring for the Wilson Conservatism Scale which are still too large to be consistent with a simple genetic model, so we cannot regard the issue as settled. The sensitivity of attitudes to cultural change may, however, make them a useful indication of the interdependence of gene expression and culture and encourage further research in this subject.

Persistence of traditional beliefs among undergraduates

JAHODA[1], Pasachoff *et al.*[2], and Salter and Routledge[3] have investigated the hypothesis that university education leads to the decline of supernatural beliefs, arriving at strikingly similar results that contradict the hypothesis. We carried out an extension of these studies at our institution. Our investigations were aimed at an evaluation of the persistence of traditional, Eastern beliefs among undergraduates.

One hundred and forty science undergraduates (100 male and 40 female), chosen at random, answered 14 questions on astronomy, astrology, superstitions, evil spirits, auspicious time, pilgrimage and sacred animals (Table 1).

The returned questionnaires were first processed by the year of study and then by sex. The options to each question—certainly believe, sometimes yes, sometimes no and certainly do not—were allotted scores of 20, 11, 9 and 0 respectively (as in ref. 1 where 0 denoted 'total unqualified disbelief' and 20, 'total unqualified belief'). For each question these scores were summed and then the sum was divided by the number of respondents, giving a 'mean belief score'. There are two questions for each topic so by averaging the two mean scores an 'average belief score' for that topic is obtained.

TABLE 1 The questionnaire

This study seeks to evaluate the degree of traditional beliefs held by the students of our college. The answers shall be treated as confidential and it does not seek to evaluate individual students. Each of the questions below are provided with four options. Please indicate clearly by an 'X' the option most relevant to you.

Personal data:

(i) Year of graduate study: 1 yr, 2 yr or 3 yr.
(ii) Sex: male or female.

The respondents were then asked to answer certainly believe, sometimes yes, sometimes no or certainly do not to the following questions.

Astronomy:

1. Do you believe that the stars and planets have any influence over your daily routine?
2. Do you believe that the appearance of a comet or an eclipse brings bad luck?

Astrology:

3. Do you believe in consulting your partner's horoscope before settling for marriage?
4. Do you believe in palmistry and numerology?

Superstitions:

5. Do you believe that Friday, the 13th, is an unlucky day?
6. Do you believe that treading on one's nails would bring misfortune?

Evil spirits:

7. Do you believe that evil spirits dwell in the grave yard?
8. Do you believe in the power of witchcraft and charms?

Auspicious time:

9. Do you believe in an "auspicious time" before setting off on important ventures?
10. Do you believe that a child must be born at an "auspicious time" to be successful in life?

Pilgrimage:

11. Do you believe that the River Ganges has the ability to wash away your sins?
12. Do you believe that shaving your head fulfills your vow to God?

Sacred animals:

13. Do you believe that the peacock (bird) is a vehicle of God?
14. Do you hold snakes and cows to be sacred animals?

TABLE 2 Average belief scores by the year of graduate study

Question	First year	Second year	Third year	All years
Astrology	7.67	7.43	7.37	7.49
Astronomy	6.05	5.96	5.85	5.96
Superstitions	8.48	8.16	8.11	8.25
Evil spirits	7.77	7.75	7.73	7.75
Auspicious time	9.99	9.72	9.42	9.71
Pilgrimage	7.01	6.95	6.83	6.93
Sacred animals	7.07	6.95	6.62	6.88
Mean	7.72	7.56	7.42	7.567
No. of subjects	42	41	57	140

A score of 5 or above was taken to indicate a persistence of beliefs. For example, with the students overall, we found an average belief score of 5.96 for the traditions in astronomy and 9.71 for auspicious time (Table 2), indicating a greater persistence of the belief in auspicious time over the astronomical traditions.

The mean score for all students and for all the questions is 7.567, indicating the prevalence of traditional, Eastern beliefs to a marked degree among science undergraduates (Table 2). But, unlike the study at the University of Pennsylvania[3], there seems to be a difference in attitude between the sexes (Table 3). This may be attributable to both the environment and sociology of Indian society. Table 2 also shows a very gradual decline in beliefs with increasing time spent at the university.

TABLE 3 Average belief scores by sex

Question	Male	Female	Total
Astrology	6.77	8.21	7.46
Astronomy	5.81	6.11	5.96
Superstitions	8.16	8.34	8.25
Evil spirits	7.21	8.29	7.75
Auspicious time	9.36	10.06	9.71
Pilgrimage	6.84	7.02	6.93
Sacred animals	5.23	8.53	6.88
Mean	7.054	8.08	7.567
No. of subjects	100	40	140

High scores of 9.71 and 8.25 for auspicious time and superstitions, respectively, may reflect the deep-rooted nature of these beliefs. It was surprising that a mean score of 5.96 was recorded for astronomy, despite it being a finite science. The vast difference in scores for sacred animals between the sexes seems to be an example of the sex-differentiated attitude towards these beliefs.

In conclusion, although our study was limited to science undergraduates, the results are similar to earlier studies[1–3]. If traditional beliefs hinder scientific training, a way must be sought for their eradication to improve our activites in science.

We thank Dr George Abraham for support.

book reviews

Indian view of research

Economics of Research and Development. By P. M. Chowdhury. Pp. xii+163. (People's Publishing House: New Delhi, (1973.) Rs18.

AT a time when national expenditure on research in the United Kingdom has declined from the vigorous growth rates of the past two decades to the current provision which barely maintains the present level of activities there is a great deal of thought about the "economics of R and D". Mr Chowdhury's subject is therefore timely.

The publication, in one volume, of eleven essays chosen by the author from a decade of his writing "about the science of science" does not have the cohesion and logical development of thought which this difficult subject undoubtedly needs. Readers will wish that the author had found the time to condense some of the more generalised essays and to link to them more coherently. He does not communicate ideas very easily and has a rather irritating habit of generalising in the conditional tense, often using technical slang unnecessarily, but the persevering reader is rewarded with nuggets of down-to-earth commonsense and useful ideas.

Those who seek methods for the evaluation of any wide-ranging national programme of research will readily agree that there are "woeful gaps in the data system" and will confirm the difficulties of quantifying research output in terms of the production of scientific papers or of the registration of patents. Few of Mr Chowdhury's scientific readers are likely to share his confident assertion that the economist is nonetheless able to select research priorities and to assess research programmes.

In the early essays it becomes clear that the author is concerned mainly with industrial research, that is with product and process studies, which are more amenable to short-range planning and assessment than are the endless surprises of the biological world in agricultural research. The part which the author considers chance to play in research is revealing in this context, and most experienced research workers will be startled to read that "it is difficult to obviate the chance factor in research" and that "it has been assumed that the impact of the chance factor in R and D sector is more or less on par with that originating in the production process in other sectors". Emphasising the greater role of state involvement in R and D in developing, as compared with developed countries, the author concentrates heavily on the industrial sector and pays too little attention to the predominantly agricultural occupations of his fellow-countrymen. In both the United States and the United Kingdom the state involvement in agricultural R and D outweighs that of the private sector.

Mr Chowdhury takes a somewhat unflattering view of scientific research workers. The image of a research manager as one who "assumes the role of an erudite scientist, an efficient organiser or a smart salesman" would startle many senior scientific administrators, but it is uncomfortably near to the truth.

These essays show that India has encountered very much the same underlying problems in the organisation of science as have the more intensively developed countries, for example that "public sector research is structurally separated from industry". Indeed the major part of the reorganisation of British public research on the basis of Lord Rothschild's advice, in three major aspects of biology, those of medicine, agriculture and the natural environment, was to overcome this separation in a highly developed economy. Mr Chowdhury's solutions are similar to those of other countries: of technically efficient scientific advisory committees, with a large measure of independence and a long and stable lease of life. The British Industrial Research Associations would be in full agreement with the author's conclusion that "sponsorship of projects by industries may make them more conscious about programming aspect of the project".

The author concludes that in many developing countries research projects of national importance have failed to receive sufficient momentum for want of really capable personnel for managing them, which summarises effectively some two decades of premature campaigns for "localisation".

The eleven essays offer comments on planning, investment and programming in R and D, balance of payments and conservation of foreign exchange, employment of scientific and technical personnel and the perspectives of development.

In a brief but illuminating foreword by Dr B. D. Nag Chaudhuri, Director General of R and D in the Ministry of Defence, there is set out very clearly the dilemma of Indian scientists, cut off by their higher standard of living from the largely agricultural problems of the population, but uneasy in their uncertain relationships with the all-powerful administration.

These essays will interest all those concerned with developing countries and should be particularly valuable for those who strive to understand the vast complexities of the modern Indian scene. H. C. PEREIRA

The poetical chemist

The Wild Uncharted Country. By Deric Bolton. Pp. 48. (Outposts: Walton-on-Thames, Surrey, 1973.) 75p.

SCIENTIFIC autobiography in blank verse is a literary genre not often attempted, but this little book shows that it can be done successfully. Although the author's note tells us that the events described are imaginary, the links with real life are close. The protagonist of the poem (he is too unheroic to be called the hero) struggles to qualify at night school; then he has a spell of chemical research at South Kensington; enters industry in the 1930s; engages in "vital war work"; returns to the chemical industry after the war; retires in the 60s; and is now concerned with environmental and ecological issues, after a lifetime as

> An ignorant chemist whose ways of life had run
> Within deep narrow channels.

His life has flowed like a river, carrying him he knows not where; his career proceeded without self-guidance, seemingly by blind chance. After he retired, the stream broadened out into a flat expanse, letting him see at last the lie of the land around. The poem gains strength from our familiarity with this Neoplatonic imagery of the individual being borne as in a boat down the turbulent stream of life, used directly in Shelley's *Alastor* and obliquely in Coleridge's *Ancient Mariner*.

A poem on so mundane a topic depends crucially on the quality of the wording, a challenge which the author meets with a fair degree of success. The writing is careful and, although there are some dull patches, the narrative flows easily and has enough imaginative moments to hold the attention. The chief flaw is that the chemist himself is too much of a puppet, with

little will of his own and no private life (or none that is mentioned). But his 'discovery' of ecology at the end brings a touch of strong, almost Wordsworthian feeling:

So, finally I chiselled out this goal:
To learn to live with nature,
not oppose it,
Exploit, burn up and devastate:
To change from miners into
farmers . . .
. . . crashing down those barriers
which divide
Science from man and man from
natural
Things and man from man and all
that is
Of simple panoramic love and
permanence.

D. G. KING-HELE

Dangerous insects

Insects and Other Arthropods of Medical Importance. Edited by Kenneth G. V. Smith. Pp. xiv+561. +12 plates. (British Museum (Natural History): London, 1973.) £6.50.

THIS is a revised and expanded edition of an earlier book by Dr J. Smart, published in 1944, which dealt mainly with the fauna of the Old World and included little biological information. The present work is much larger, covers the whole world and is by 16 authors. The primary purpose of the book is still to enable non-specialists to identify to generic or subgeneric level arthropods, especially insects, of medical importance. Many species which are essentially parasites of animals are also included because many of them also attack man, if only on rare occasions. It will probably come as a surprise to the non-specialist to learn that several moths feed on eye liquids of vertebrates and that one is even capable of piercing the skin and sucking blood.

Three hundred of the 523 pages are devoted to the order Diptera whose importance has been greatly increased by the recognition of many new viruses. Of the 553 different combinations of vector and disease listed in their tables summarising the records, 10 involve bacteria, 47 nematodes, 90 protozoa, 11 rickettsias, 9 spirochaetes and 386 viruses (mostly carried by mosquitoes and recognised in the past 30 years). Many of these viruses are, of course, very localised and often quite unimportant and the long known diseases such as malaria, plague and typhus are much more serious. Nevertheless, the only arthropod groups of much importance in disease transmission besides the Diptera are the Siphonaptera (fleas) and the Acari (ticks and mites). Though disease transmission is the chief way in which insects are medically important, they may also be troublesome by biting or stinging, or by fragmenting into particles which are irritating or to which man may become allergic. Even scorpions which are relatively rare may kill 1,000 people, mostly young children, each year in Mexico.

The illustrated keys for the identification of all the more important groups are excellent and will be very useful to anyone with some knowledge of entomology. In most groups, there are also keys for the identification of the early stages (larvae and pupae). The information about the biology of the various groups and of the kind of trouble they cause is concise but sufficient, together with the long lists of references, to give a useful introduction to the subject.

Readers should note that a short mimeographed list of errata has been inserted in each copy. It is chiefly concerned with some errors in the names of groups of Acari in the table of disease vectors.

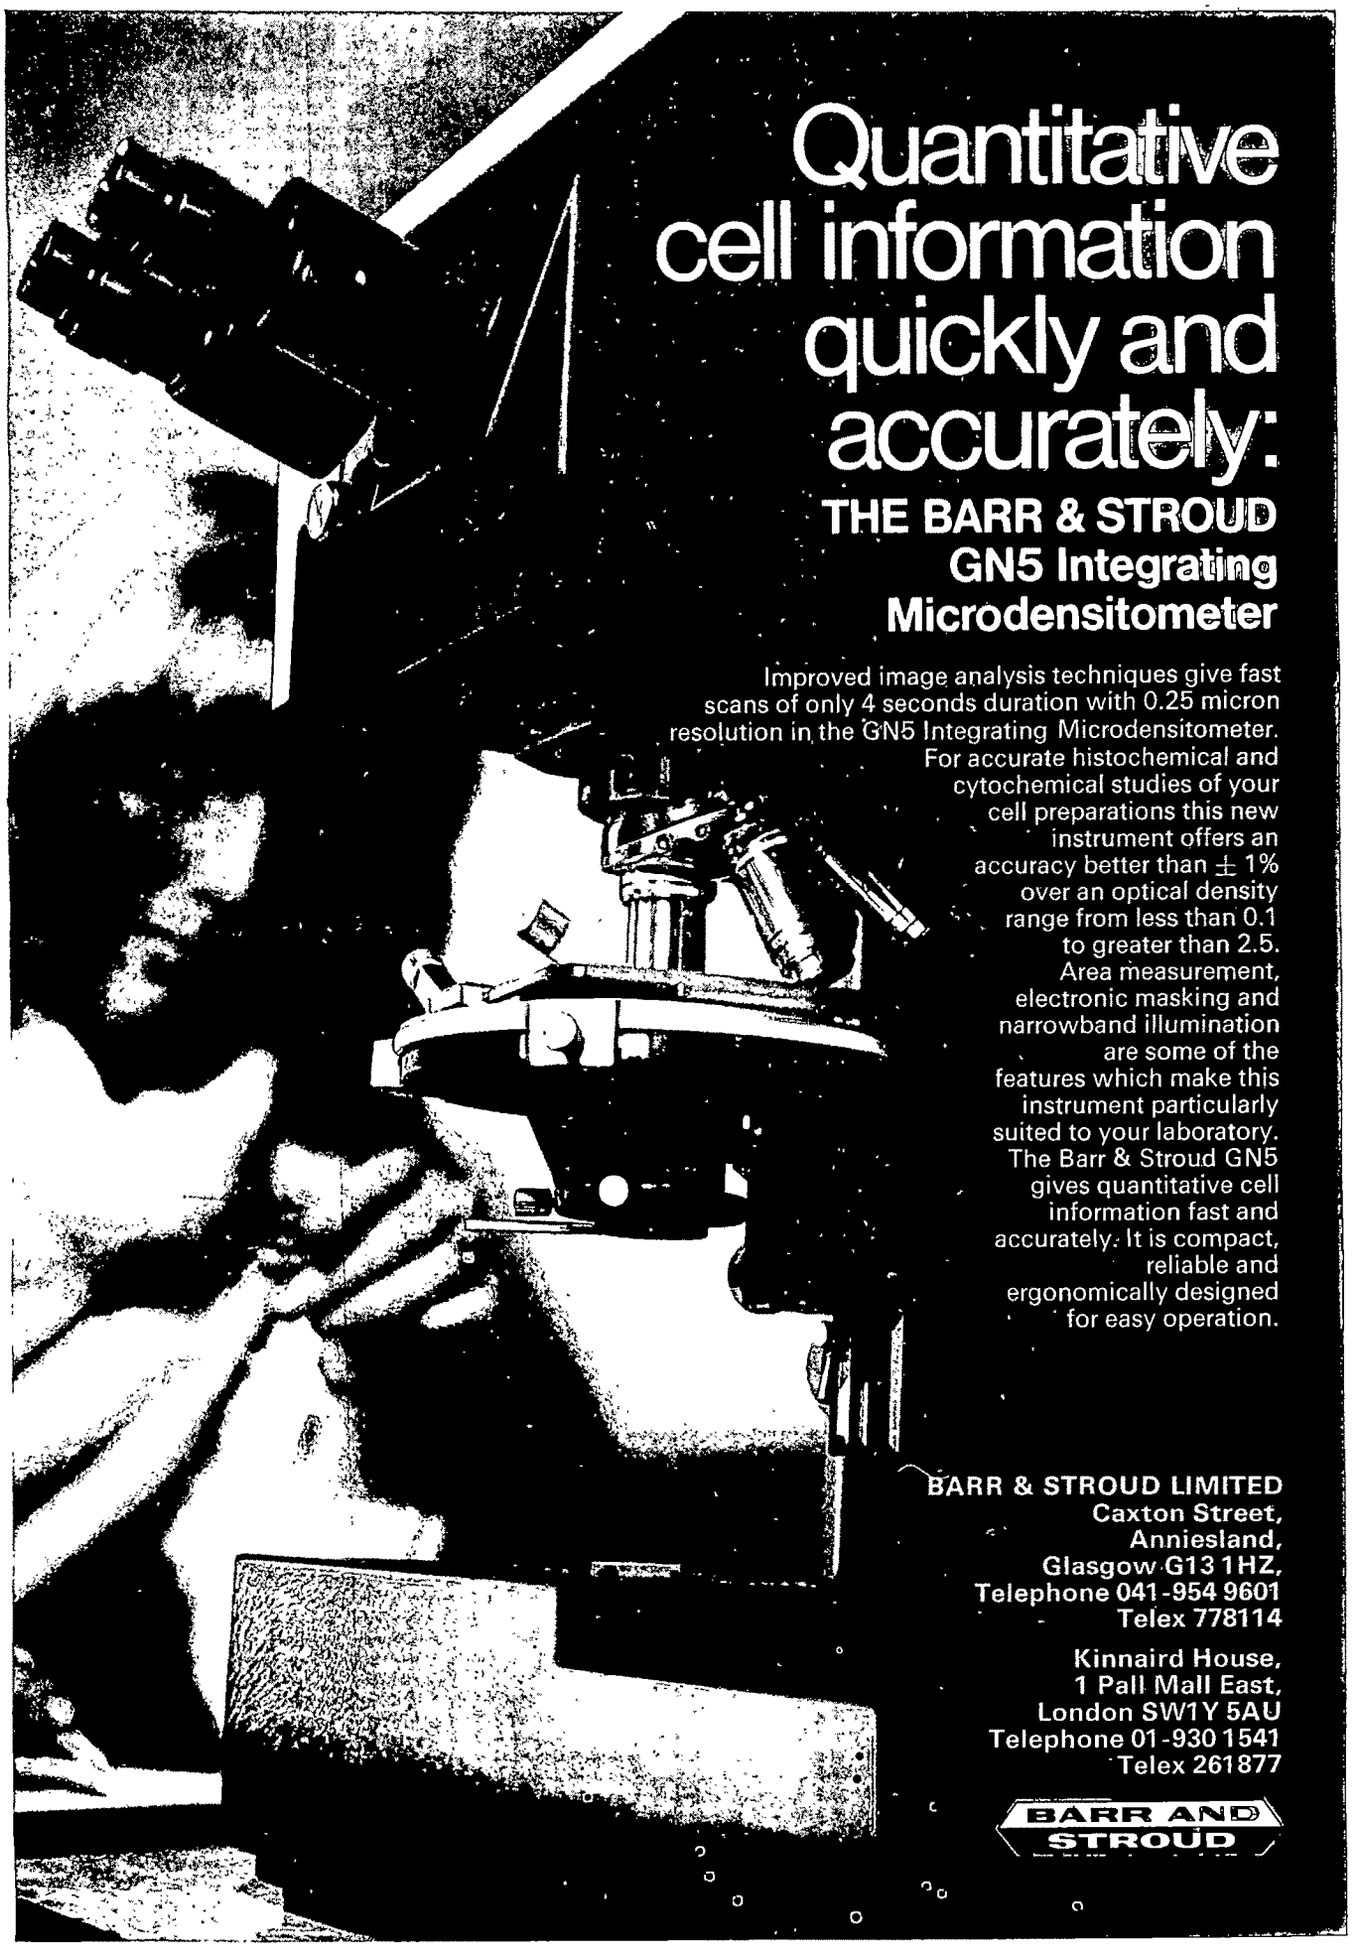
O. W. RICHARDS

Halides galore

The Chemistry of the Carbon-Halogen Bond. Edited by Saul Patai. Part 1: Pp. xiii+1-608; part 2: Pp. xiii+609-1215. (Wiley-Interscience: London and New York, December 1973.) £22 (two volumes).

Fluorine in Organic Chemistry. By R. D. Chambers. Pp. xv+391. (Interscience Morographs on Organic Chemistry.) (Wiley-Interscience: New York and London, January 1974.) £10.75.

THE first monograph deals with the thirteenth functional group to appear in Professor Saul Patai's monumental series, now within sight of completion. As with previous volumes, editorial policy has been to go to press without promised chapters that had not been received by a deadline. This time there are five casualties: formation of C–X bond; modern synthetic uses of organic halides; synthesis and uses of isotopically labelled halides; fluorocarbons (see below); and, finally, optical rotatory dispersion and circular dichroism of organic halides. Of these the first two are losses indeed.



There are, however, plenty of interesting and valuable articles in what remains. Among them are: heterolytic mechanisms of substitution involving carbon-halogen bonds (P. B. D. de la Mare and B. E. Swedlund, 141 pages); directing, activating and deactivating effects (G. Modena and G. Scorrano, 106 pages); elimination reactions in solution (R. A. More O'Ferrall, 68 pages)—three excellent reviews on major aspects of the subject that are of general interest. There is also an interesting chapter on homolytic mechanisms of substitution (E. S. Huyser, 60 pages), but as this deals entirely with C–H→C–X, it seems to belong more appropriately under alkanes. Then there is a series of chapters dealing with more specialist aspects of the C–X linkage: mass spectrometry (A. G. Loudon, 42 pages), pyrolysis (K. W. Egger and A. T. Cocks, 70 pages), photochemistry (P. G. Sammes, 48 pages), radiation chemistry (R. E. Bühler, 70 pages), biochemistry (S. Doonan, 52 pages), electrochemistry (J. Casanova and L. Eberson, 70 pages) and thermochemistry (R. Shaw, 23 pages).

There is a very long chapter on analysis of organic halogen compounds (J. Zabicky and S. Ehrlich-Rogozinski, 160 pages) which, though interesting, seems to be overweight compared with space devoted to other topics. There are the usual introductory chapters on general and theoretical aspects of the carbon–halogen bond (G. H. Wagnière, 48 pages) and structural chemistry of the C–X bond (J. Trotter, 14 pages); and also one on hydrogen bonding and complex-forming properties (J. W. Smith, 36 pages). Then there are the topics that don't quite fit in anywhere else; perchloro-, perbromo- and periodo-compounds (T. Chivers, 62 pages), and, last of all, rearrangements involving halides (C. Raape, 44 pages—an interesting chapter with a good account of Favorskii and Ramberg–Bäcklund rearrangements.

All in all a good volume, though as with previous volumes one is often puzzled at the way in which space is allocated between the various topics. The reproduction of structural formulae is in general fairly good, and the layout relatively clear. Literature coverage seems to be very thorough, but to extend only into 1971 (the end?), with some citations extending into 1972 in a few articles.

The non-delivery of the fluorocarbon chapter in Professor Patai's collection is more than compensated for by the appearance of Dr Chambers' book. This does not set out to provide synoptic coverage of the subject, but seeks to place selective aspects in a general mechanistic framework, for example, total, and selected, fluorination; replacement of OH by F; nucleophilic displacement of F; eliminations; polyfluoroaliphatics and aromatics; organometallic compounds. It is an interesting, useful and well documented survey, but the author is ill served by bad layout and by poor unattractive representation of reaction schemes. Literature coverage is essentially till the end of 1971.

PETER SYKES

Quantitative cell information quickly and accurately:

THE BARR & STROUD GN5 Integrating Microdensitometer

Improved image analysis techniques give fast scans of only 4 seconds duration with 0.25 micron resolution in the GN5 Integrating Microdensitometer. For accurate histochemical and cytochemical studies of your cell preparations this new instrument offers an accuracy better than ± 1% over an optical density range from less than 0.1 to greater than 2.5. Area measurement, electronic masking and narrowband illumination are some of the features which make this instrument particularly suited to your laboratory. The Barr & Stroud GN5 gives quantitative cell information fast and accurately. It is compact, reliable and ergonomically designed for easy operation.

Electrophoresis and Isoelectric Focusing in Polyacrylamide Gel

Advances of Methods and Theories, Biochemical and Clinical Applications

Editors: R. C. Allen and H. R. Maurer

1974. Large-octavo. 316 pages. With 115 illustrations and 19 charts. Cloth DM 105,–
ISBN 3 11 004344 0

This book presents theory along with its practical application of electrophoresis and isoelectric focusing in polyacrylamide gel as applied to present day biology and medicine. Papers dealing with the theory and techniques of separation, quantification and preparation methods for proteins, lipoproteins, protein inhibitors isozymes, polypeptides and nucleic acids are included.

Molecular Biology comes of age

This special **Nature** Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, **'Molecular Biology Comes of Age'** looks back on the circumstances surrounding the original appearance in **Nature** of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development of Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'Molecular Biology Comes of Age' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of **'Molecular Biology Comes of Age'** are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 pro rata). Please order copies by completing the form below and returning it with the appropriate fee.

Circulation Department, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

THE ALGAE
Second Edition
V. J. Chapman and D. J. Chapman

A completely rewritten and updated second edition of this successful student text. Information included ranges from a taxonomic survey of the principal divisions, classes and orders of the algae to a discussion of such topics as Ecology, Physiology and Bio-geography. Although the overlying approach of the book is general rather than specific few student texts are so comprehensive in their coverage.
£6.95

EVOLUTION AND PLANTS OF THE PAST
Harlan P. Banks

A wide-ranging discussion of a number of important aspects of palaeobotany. The basis of the approach is an examination of the way in which plants have developed from the earliest times, but in contrast with the more traditional approach, in which each group of plants is examined separately, this book looks at each geological period and treats its fossilflora as a whole.
'Dr. Banks' successful blend of scholarship and zest is manifest, and this book can be thoroughly recommended to students of palaeobotany'

Crystal defects

Computed Electron Micrographs and Defect Identification. By A. K. Head, P. Humble, L. M. Clarebrough, A. J. Morton, and C. T. Forwood. Pp. x+400. Defects in Crystalline Solids, vol. 7. (North-Holland: Amsterdam and London; American Elsevier, New York, 1973.) DFl 100; $35.10.

THE interpretation of electron micrographs of thin foils of crystalline material involves two radically different aspects: first, the morphology and orientation relationships of features such as precipitates, transition phases (for example, Guinier-Preston zones) and twins; second, the geometrical characteristics of crystal defects such as dislocations, stacking faults and point-defect aggregates. The first task involves simple examination of micrographs and matching of the diffraction patterns of selected areas, and offers no particular challenges to the experienced microscopist; the second is far more difficult, since the image (for instance) of a dislocation is really the image of a local distortion in the crystal lattice, and to identify the geometrical characteristics of the defect (Burgers vector, stacking parameters, and so on) requires the investigator to deduce the details of the lattice distortion from the appearance of the image under different imaging conditions. In fact, several images of the same defect are needed to interpret it securely.

The established way of identifying the Burgers vector of a dislocation is to find an imaging mode which causes the dislocation to disappear, but this method has limitations, especially with elastically anisotropic materials. The other method involves generating a theoretical image, with the aid of a computer program and pictorial print-out, for a particular set of imaging conditions, and comparing the theoretical image critically with that photographed in the electron microscope.

This book is the first detailed presentation of this computer technique, by a team of Australian authors led by A. K. Head, who originated the technique seven years ago. The book includes an outline of the two-beam dynamical theory which is the theoretical basis of the method; a full account, with many examples, of the practical steps involved in orienting a crystal, identifying the diffraction vector, dislocation line direction, and so on; the principles and details of the several computer programs, for both cubic and non-cubic crystals; and the methods for matching experimental and theoretical images. Finally the uses and limitations of the method are outlined.

The book is very much a practical operator's handbook; while its main use of course is to show the reader how to compute images, it will also be useful for the beginner who is learning how to orient foils and features in foils. Altogether, this is an impressive compilation by a group of pioneers who have stayed the course and finished the job.

R. W. CAHN

Quaternary fossil plants

Quaternary Plant Ecology. Edited by B. J. B. Birks and R. G. West. (The 14th Symposium of The British Ecological Society, University of Cambridge, 28–30 March, 1972.) Pp. ix+326. (Blackwell Scientific: Oxford and London, 1973.) £13.

THE relation between the ecology of plants, as seen today, and the study of fossil assemblages of plant remains from the Quaternary period has always been an exchange of information and ideas in both directions. It is generally realised that any attempt to interpret what an assemblage of fossil remains really represents, must depend on a knowledge and understanding of modern vegetation and the ecology of the constituent species. In return, the study of fossil assemblages leads to a much better appreciation of the extent to which the composition of present day vegetation depends on its history, both directly and indirectly through concurrent changes in the soil. The papers presented at this symposium are primarily concerned with the first relationship, that is, the ecology of the past but quite clearly a better knowledge of the past helps understanding of the present.

The first four sections, containing eleven papers, are directly concerned with methodology and the process of matching assemblages of pollen, or in one paper, other fossilised parts of plants, with modern vegetation. It is at once clear that a technological revolution has taken place as a consequence of the use of the proportions of carbon isotopes to give an independent estimate of the absolute age of a deposit. This allows the rate of deposition of a sediment to be calculated and thus pollen contents can be measured in absolute, rather than relative terms. This has stimulated a much more fundamental approach to the problem of relating the quantity of pollen deposited on unit area in unit time to the actual representation of species in the surrounding vegetation. Studies of the production of pollen, its dispersal in the air, its redistribution in water and its preservation are all included. These sections provide a fund of information and ideas which should be read by all palynologists.

The fifth section contains four papers concerned with the evidence from quaternary studies of the rates of change in vegetation over long periods, including both natural processes and changes for which man is largely responsible. The sixth section is devoted to limnological studies which demonstrate the value of interdisciplinary studies using palynology and stratigraphic analysis of a variety of aquatic organisms.

Symposia tend to be rather uneven in their coverage and often include papers of relatively light weight. The very opposite seems to be true in this case. Those who planned, organised and reported the meeting are to be congratulated on bringing together so many stars each of such magnitude into a single constellation and on producing an outstanding contribution to the literature of palaeoecology.

C. D. PIGOTT

Eccentric extracts

Strange Phenomena: A Sourcebook of Unusual Natural Phenomena, Vol. G-1. Compiled by William R. Corliss. Pp. 277. (Corliss: Glen Arm, Md 21057, 1974.) $6.95.

As the flow of letters we receive whenever *Nature* publishes anything about ball lightning testifies many of our readers are interested in bizarre phenomena at the fringe of scientific understanding. That is as it should be; only by such interest can any of these phenomena be brought within the fold of science proper, just as continental drift has gained respectability during this century. So the publication of this sourcebook is likely to meet with a warm response.

Corliss has collected what he calls "homeless facts" and given them a home, in the form of a collection of brief reports (some no more than 200 words) culled from the scientific, pseudoscientific and unscientific literature. The task is far from complete, and we are promised further volumes as the work progresses; the present edition is in the form of a ring-binder, so that necessary additions or deletions can be made conveniently.

Some examples culled from a random search of the pages suffice to give an impression of the book's scope: ball lightning, flames from the sky, earthquakes and lightning, strange detonations (barisal guns and the like), sunspots and rainfall, and so on. The march of science is such that the last of these phenomena has already been received into the bosom of 'serious' science, and most of the oddities which are mentioned are far from the lunatic fringe of flying saucers and little green men.

The net cast by Corliss has gathered a harvest from many sources, and *Nature* is lavishly represented. But it is a curious feature of the extracts from this journal in particular that they are clustered distinctly in time about two peaks, the first about 100 years ago and

the second in the past few years. This may reveal something about the collection technique used by Corliss, or about this journal, or about the general awareness of such phenomena and 'things that go bump in the night'; I doubt if it reflects a genuine distribution of such oddities. But the discovery of such a pattern shows just one example of the way in which the book can provide hours of harmless fun. At the price, it is excellent value for entertainment alone; there is also the added bonus that such a collection must inevitably include something which will become 'reputable' in the near future. Owners of the volume will then be able to say "Of course, I knew all about that back in 1974".

JOHN GRIBBIN

Plan the countryside

Rural Resource Development. By M. C. Whitby, D. L. J. Robins, A. W. Tansey and K. G. Willis. Pp. 243 (Methuen: London, January 1974.) £2.50 cloth; £1.30 paper.

THE main concern of the authors is to present ways of analysis which will lead to more effective public decision making and lead to the better use of rural resources. At present many of the decisions affecting the countryside are reached in an illogical way; because recommendations at officer level concentrate on only a selected scheme, because of political considerations, because of the influence and pressure of organisations such as the Country Landowners' Association, the National Farmers' Union, and strong amenity bodies.

This book gives the elements of the economic theory of resource allocation to provide a framework for understanding the economic processes at work in the countryside; private rural economy is well documented whereas public issues have received less attention. The authors explore in some detail the factors which do, as well as those which should, lead to decisions. They contend that most public agencies seem to pursue inappropriate objectives under incorrectly specified constraints, and that suboptimal decisions are taken because cash revenue and expenditure are used instead of the assessment of social costs and benefits.

There is a chapter on recreation, conservation and amenity which explores the general question of allocating land to physically non-productive uses and of measuring the less tangible consequences of such allocation decisions. There is discussion of the very difficult subject of estimating the amenity value of land.

There are useful chapters on the statutory British planning system and on population trends and transport in rural areas. A better understanding of all these matters would enable judgments to be made which used resources more efficiently, not only in cash terms, for society.

It can certainly be justly claimed that this is a useful source book for planners, landscape designers, students of environmental studies, agricultural economics and rural geography. There is an excellent list of references and a good index.

GEOFFREY BERRY

Free radicals

Free-radical Chemistry: Structure and Mechanism. D. C. Nonhebel and J. C. Walton. Pp. xv+572. (Cambridge University: London, January 1974.) £15; $35.

RAPIDLY growing scientific subjects periodically need exposition in comprehensive textbooks and it is many years since this subject has received an adequate broad survey that meets the requirements of both senior undergraduates and research workers. Recent quantitative measurements, mainly by gas chromatography and ESR spectroscopy, have so greatly enhanced knowledge of chemical reactions that publications of only 10 years ago are no longer factually correct and contain some theoretical deductions that are no longer fully valid.

This book from Scotland, which is now a very active region for research in free radical chemistry, meets a real need. It is a collaboration between a physical (Dr Walton) and an organic chemist (Dr Nonhebel) who have surveyed harmoniously physical measurements, gas reactions, reactions of atoms and simple alkyl radicals, as well as a wide range of more complex reactions in solution. They have paid particular attention to recent work and theories.

Polymer chemistry has been omitted for lack of space. But though polymerisation technology is still expanding its theoretical basis is changing but little and has been covered reasonably well in a long chapter on reactions of alkyl radicals.

A particularly long chapter is accorded to radical oxidations and reductions. This, a rapidly expanding sector of free radical chemistry, certainly merits its detailed treatment, but the text gives far too much space to phenol oxidation in comparison with autoxidation or possibly to reactions involving transition metal ions which, for students, deserved particular attention since they bridge the deleterious scholastic gap between inorganic and organic chemistry.

Only the price should detract from the wide use of this excellently produced book.

W. A. WATERS

Life in the sea

Biological Oceanographic Processes. By Timothy R. Parsons and Masayuki Takahashi. Pp. x+186. (Pergamon: Oxford and New York, October 1973.) £4.

THIS reads like the summary of an excellent four- or five-volume treatise that, unfortunately, has never been written. The authors insist that it is no more than an introduction to biological oceanography. A reader with no previous knowledge of the subject could, indeed, start from first principles. By page 10 he would reach the mathematics of diversity indices; four or five pages later he would cope with the application of statistics to the interpretation of samples; by page 21 he would have polished off biogeography and started on time-series variability.

The authors maintain this pace throughout. No new term is introduced without an excellent definition. One cannot even quarrel with their one non-definition: of detritus, they say that "while the word lacks definition it should not be regarded as lacking in importance" and then, having paused, off they go again and deal with the physics and chemistry of detritus in great depth—in four pages.

The book deals, almost exclusively, with near-surface pelagic populations, their environment and their ecological processes. Benthic, littoral and bathypelagic systems are excluded. Indeed, almost everything is excluded that cannot be expressed in quantitative terms—and preferably summarised as an equation.

Some sections are superficial but what else can one expect in a book of such breadth? There are chapters dealing with the distribution and chemical composition of plankton, nutrients and seawater, heterotrophic and autotrophic processes, plankton feeding and production, organic and inorganic cycles and the transfer of energy and materials in the food chain. The authors claim that it is not a literature review but nearly 700 well-chosen references, alone, justify the purchase price of the book.

The last chapter, "some practical problems in biological oceanography", is trivial and unnecessary. Otherwise, this is an excellent book for professional oceanographers, biologists or, indeed, as the authors put it, "scientists in other professions who may require some quantitative expressions of biological oceanographic phenomena".

R. S. GLOVER

obituary

O. M. B. Bulman

PROFESSOR OLIVER MEREDITH BOONE BULMAN, FRS, who died at the age of 71 on February 18 was generally recognised as the leading authority on the graptolites, the group of colonial organisms which came into being, flourished and died out in the Lower Palaeozoic.

Bulman was trained as a geologist at Imperial College where he remained to carry out research under the direction of W. W. Watts. Among fellow students investigating various aspects of the Palaeozoic rocks of Britain at that time were Stubblefield, Whittard, Mitchell, Howell and David Williams all of whom were to hold posts of distinction.

Bulman has recorded that he was first attracted to the graptolites by beautifully preserved specimens of *Dictyonema* in the Sineton shales, on which he and Stubblefield were working; and he took this as the subject for his first palaeontological investigations. From the first, he concentrated on well preserved material which he prepared and figured with great skill. In this way he was able to establish details of the external form, and in many instances, of the internal structure. With this new information he was particularly sucessful in elucidating the early stages of the growth of graptolites. When he completed his tenure of a Senior Studentship of the Royal Commission for the Exhibition of 1851, it was said that only a man of exceptional talent could have produced the results he had by then achieved.

After holding demonstratorships in the Zoology and Geology Departments at Imperial College, Bulman was appointed in 1931 to a post in the Sedgwick Museum where he remained for the rest of his academic life. In 1945 he became Reader in Palaeontology and in 1955 was appointed Woodwardian Professor of Geology. In 1945 he was elected a Fellow of Sydney Sussex College. He was President of Section C of the British Association in 1959 and received in succession the Lyell Fund and the Lyell Medal from the Geological Society of which he was President from 1962–64. He was connected with the *Geological Magazine* either as Editor or its advisor for 40 years.

Throughout his career the study of graptolites remained his principle scientific concern. He continued as he had begun with a series of meticulous accounts which covered graptolites not only from Britain, but from North America, Scandinavia and Asia. He acquired an immense knowledge of their worldwide distribution which he put to use in his discussions of their mode of life and of the steps by which the graptolites evolved. He expressed his conclusions cautiously leaving the reader in no doubt where uncertainty existed.

Whatever the future may hold Bulman's part in the elucidation of the graptolites is likely to remain as a landmark in studies of Palaeozoic life.

Awards

The **Wellcome Prize** for 1974 has been presented to **J. H. Wilkinson.**

The **National Academy of Sciences** has presented the **Henry Draper Medal** to **L. Spitzer, Jr;** the **United States Steel Foundation Award in Molecular Biology** to **D. Baltimore;** the **Gibbs Brothers Medal** to **P. Eisenberg;** the **Selman A. Waksman Award** to **R. Dulbecco;** and the **NAS Award in Environmental Quality** to **G. E. Hutchinson.**

The **1974 Lenin Prizes** for science and technology have been awarded to: **L. V. Keldysh, Y. G. Abov, P. A. Krupchitskii, V. M. Lobashev, V. A. Nazarenko, A. V. Kirsanov, N. V. Belov, A. I. Opanrin, I. I. Mints, V. D. Timakov, G. Ya. Kagan, A. I. Nesterov, E. M. Tareev** and **A. I. Strukov.**

Miscellaneous

The **George Von Hevesy Prize** will be awarded for papers on the subject of Nuclear Medicine at the First World Congress of Nuclear Medicine in Tokyo (Professor W. Horst, Clinic of Nuclear Medicine, University of Zurich, Ramistrasse 100, 8006 Zurich, Switzerland).

The **Edna McConnell Clark Foundation** of New York announces a programme of support for research projects on schistosomiasis (Dr Donald B. Hoffman, Jr, Vice President, The Edna McConnell Clark Foundation, 250 Park Avenue, Suite 904, New York, New York 10017).

Erratum

In the article "Additional location of metalliferous sediments in the Red Sea" by R. D. Bignell *et al.*, (*Nature* **248,** 127; 1974), as the result of a printer's error, the following corrections should be made. Page 128, line 15 should read "possibility exists of further deposits at depth. Analysis of . . ." and line 29 should read "possibility that they formed as a result of the oxidation of . . .".

International Meetings

May 22, **Herbal Remedies in Europe** (Professor J. M. Rowson, Pro-Vice-Chancellor, University of Bradford, Bradford, UK).

APPOINTMENTS VACANT

UNIVERSITY OF LEICESTER

The Department of Physiology has a vacancy for a Laboratory Technician Grade III (salary scale £1,650 to £1,920) for research and teaching practical duties. Applicants should have ONC/OND or equivalent qualifications and have had 3 to 5 years laboratory experience. The work will largely consist of electrophysiological techniques and a good knowledge of electronics is essential.

Applications with full curriculum vitae together with the names and addresses of 2 referees should be sent to the Chief Technician, Department of Physiology, University of Leicester, Leicester, LE1 7RH, as soon as possible. (1814)

SENIOR TECHNICIAN

required to assist and supervise research haematology laboratory. Whitley Council Scales and Conditions. Applications in writing enclosing curriculum vitae and the names of two referees to the Secretary, University College Hospital Medical School, University Street, London WC1E 6JJ quoting reference ERH/ST. (1816)

ST. MARY'S HOSPITAL MEDICAL SCHOOL
RESEARCH TECHNICIAN

required in Department of Experimental Pathology to form one of team studying effects of drugs in cancer and organ transplantation. Commencing salary within scale £1,440 to £1,664 plus £126 London Weighting p.a. Apply, The Secretary, St. Mary's Hospital Medical School, Paddington, London W2 1PG quoting Ref. EPN2. (1830)

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF PHYSICS

Applications are invited for two postdoctoral Research Assistants, sponsored by the Science Research Council. The first is for theoretical work, under Dr. C. A. Bates, on Spin-Phonon Interactions, and the second is for theoretical work, under Professor K. W. H. Stevens, on Many-Electron Theory of Magnetic Materials. Experience in related fields is desirable. Salary, according to age and experience, on the Lecturer scale.

Applications in writing giving full details of qualifications and experience to Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD as soon as possible. Names of two referees should be given. (1818)

UNIVERSITY OF BERN
Switzerland
INSTITUTE OF GENERAL MICROBIOLOGY

A Post-doctoral Research Assistant is required to work on the analysis of yeast-tRNA as studied in mutants defective in the structural and modificator genes of suppressor tRNA. Previous experience in the field is necessary. The post is for up to two years with a minimal salary of Swiss Fr 2500 monthly and possibilities of renewing, commencing on or after May 1974. Write with a curriculum vitae and the names of two referees to Dr. R. Fluri, Institute of General Microbiology, Altenbergrain 21, CH-3013 Bern, Switzerland. (1836)

UNIVERSITY OF BIRMINGHAM
WEST MIDLAND REGIONAL HEALTH AUTHORITY

M.Sc., Course in Clinical Biochemistry

Applications are invited for the appointment of twelve basic grade biochemists for a two-year course for the M.Sc. Degree in Clinical Biochemistry commencing on October 1, 1974, and based on the following hospitals:

Coventry and Warwickshire Hospital, Coventry
Dudley Road Hospital, Birmingham
East Birmingham Hospital, Birmingham
General Hospital, Burton-on-Trent
Good Hope Hospital, Sutton Coldfield
Guest Hospital, Dudley
Royal Salop Infirmary, Shrewsbury
North Staffordshire Royal Infirmary, Stoke-on-Trent
Royal Hospital, Wolverhampton
Selly Oak Hospital, Birmingham
Warwick Hospital
Worcester Royal Infirmary

The course is organised by the Departments of Clinical Chemistry and Biochemistry. The course is open to probationary basic grade biochemists in the National Health Service and other selected candidates who must possess a 1st or 2nd Class Honours Degree in Chemistry or Biochemistry or hold an equivalent qualification.

The object of the course is to provide a thorough training in all aspects of clinical biochemistry than is possible in the usual two years probationary period.

Initial selection will be by the University and successful candidates will then be interviewed by the area Health Authority concerned of whose staff the candidate will be a member. The University course fee of £45 will be paid by individual candidates, otherwise salary paid in accordance with approved N.H.S. scale.

Application forms from the Assistant Registrar (Science), University of Birmingham, Edgbaston, Birmingham B15 2TT, to be returned by May 31, 1974. (1825)

At the

DEPARTMENT of PHYSICS and ASTRONOMY

a position is vacant for a

full Professor of Technical Physics

who will undertake **research** and **education** in fields related to the **energy problem,** including its **environmental aspects.**

Applicants should have conducted research of outstanding quality in physics or an allied discipline and should have shown actual interest, and preferably have participated in the above fields. Industrial or comparable experience would be an advantage. Candidates should be interested in interdisciplinary studies and have a capacity for, and preferably experience with teaching. Knowledge of the Dutch language is not a prerequisite.

Resources are available to develop an adequate research programme to be carried out by Ph.D. candidates.

Details of the salary, of the conditions of service, and of the method of application, may be obtained by writing to Professor C. Th. J. Alkemade, Physical Laboratory, Sorbonnelaan 4, University, Utrecht, The Netherlands. (Tel. No. 030-533302). (1846)

UNIVERSITY OF BRISTOL
Long Ashton Research Station

HEAD OF HOME FOOD PRESERVATION SECTION

Applications are invited for the appointment of a graduate to Head a small team, financed by the Ministry of Agriculture, Fisheries and Food, that is concerned with improving methods of home food preservation, particularly freezing, and other aspects of the domestic handling and storage of foodstuffs.

The work includes analysis, investigations and experiments leading to recommendations and advice to users, and the dissemination of information by publications, lectures and short courses.

Applicants should have had experience in the food field and hold a good science degree, preferably in Biochemistry, Food Science or Nutrition or equivalent qualifications. Lecturing and contact with the public will be the special responsibility of the successful candidate.

Appointment will be made in the Principal Scientific Officer grade (salary at present under review—£3,715 to £4,895 per annum). Superannuation under F.S.S.U. with allowance to offset contributions.

Applications to the Secretary, Research Station, Long Ashton, Bristol BS18 9AF, by June 11, 1974. (1822)

IRELAND

Biochemist Principal Grade

South Eastern Health Board

Salary: £3,039 to £4,051.

Essential: M.Sc. in Biochemistry or Physiological Chemistry or equivalent and five years experience in Clinical Biochemistry and/or Chemical Pathology in the laboratory of a hospital or allied institution.

For application forms and further particulars write to: **Secretary, Local Appointments Commission, 45 Upper O'Connell Street, Dublin 1.**

Latest date for receiving completed application forms:

30th May 1974

(1839)

UNIVERSITY OF DUBLIN
Trinity College

CHAIR OF OBSTETRICS AND GYNAECOLOGY

Applications are invited for the above full-time appointment. The Professorial Unit is situated in the Rotunda Hospital and the Professor also has facilities for Gynaecology at the Adelaide Hospital.

Further details concerning this appointment may be obtained from:

Mr. G. H. H. Giltrap,
Secretary to the College,
Trinity College,
Dublin 2.

to whom completed applications should be returned if possible, by the 5th June, 1974. (1843)

UNIVERSITY OF ABERDEEN
Research Assistant in Genetics

Applications are invited for the above post. The work involves electrophoresis, ultracentrifugal analysis and quantitative estimation of plasma lipoproteins. Appropriate experience and qualifications in Biochemistry or Chemistry are desirable.

Salary on scale: £1,662 to £2,304 with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by May 25, 1974. (1837)

UNIVERSITY OF ST. ANDREWS
DEPARTMENT OF ZOOLOGY

Applications are invited for a post of RESEARCH ASSISTANT to work on the genetic control of the expression of cell-surface antigens in protozoa. Candidates should have a good honours degree in Biology. Experience in cell culturing, microbiology or immunology would be an advantage. The post is financed by the Medical Research Council and is tenable for three years from September 1, 1974; salary scale £1,500 by £150 to £1,800 (under review).

Applications, giving details of education and qualifications together with the names of two referees, should be lodged with the Establishments Officer of the University, College Gate, St. Andrews, Fife KY16 9AJ by May 31, 1974. (1832)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for the following:

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH
RESEARCH FELLOW IN MICROBIOLOGY

Groups in the Department of Microbiology work on different aspects of animal virology and immunology. The Department is well equipped for all types of biochemical and biological studies in these fields. Preference will be given to candidates with experience in work on the nucleic acids of viruses, particularly by electron microscopic techniques. Applicants should have a Ph.D. degree and some postdoctoral experience.

Enquiries on academic aspects of this position should be addressed to Professor G. L. Ada, F.A.A., Head of the Department of Microbiology in the University. Closing date: **June 7, 1974.**

SENIOR RESEARCH FELLOW IN PHYSIOLOGY

Appointment will be in the Department of Physiology (Head: Professor P. O. Bishop, F.A.A.). The successful applicant will be expected to work in the general field of comparative neurophysiology of vision. Closing date: **June 7, 1974.**

FACULTY OF SCIENCE
POSTS IN THE DEPARTMENT OF FORESTRY

Two posts are available in the Department. (Head: Professor J. D. Ovington), one at the level of **Lesturer** and the other at the level of **Tutor.** The appointees will be required to take up duty as soon as possible. Applicants should be graduates in science or forestry having appropriate experience in one of the following topics: Dendrology, Fire, Soils and some aspect of Tropical Forestry. Closing date: **June 10, 1974.**

SALARIES: Salary on appointment will be in accordance with qualifications and experience within the ranges: Senior Research Fellow $A12,778 to $A15,116 p.a.; Research Fellow $A8,698 to $A11,901 p.a.; Lecturer $A8,698 to $A11,982 p.a.; Tutor $A5,740 to $A7,015 pa.; current exchange rates are approximately $A1: 67p; $US1.49.

OTHER CONDITIONS: Tenure—Senior Research Fellow and Research Fellow normally for three years in the first instance with the possibility of extension to a maximum of five years; Lecturer for three years in the first instance with provision for reappointment to retiring age; Tutor normally for twelve months in the first instance with normal expectation of yearly renewal up to five years.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation is on the F.S.S.U. pattern with supplementary benefits.

Travel expenses from overseas (except New Zealand) are not provided for posts at the level of tutor but assisted passage can be considered for a person offered appointment from the United Kingdom who intends to settle permanently in Australia.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF for further particulars before applying. (1828)

Senior Microbiologist

Chemotherapeutic Research from £4000

This is a research management appointment for a graduate who has several years' chemotherapeutic experience in an industrial environment, and who now feels ready and able to take on a more senior position.

Our client is a large and well-known pharmaceutical company with a firmly established reputation in the field of antibiotics research. The present appointment is a completely new one, and it arises at a time when the Company is committed to a substantial research expenditure programme over the next few years.

The laboratories are extensive and well-equipped, and are located in a pleasant country area of Southern England.

The man (or woman) appointed will manage a team of about four people who are responsible for the detailed evaluation of potential new human antimicrobial agents – after they have successfully passed the Company's primary screening programme. His group will progress promising compounds to the stage where the Project Committee, of which he will be a member, can decide whether or not human trials are justified. When they are, he will play an important role in coordinating laboratory studies with the human volunteer and patient studies.

The work will involve extensive interdisciplinary cooperation with chemists, clinicians and other research teams, and may necessitate some travel within Europe.

Applicants should be graduates within the approximate age range 30–40 and with several years' experience of antimicrobial research in the pharmaceutical industry. A higher degree is not essential, but evidence of good research ability will certainly be sought. A wide knowledge of *in vivo* as well as *in vitro* test systems is called for, together with the capacity to develop new models and procedures.

Starting salary is likely to be at least £4000, but could be substantially higher for a particularly suitable candidate. Other benefits include a bonus scheme, contributory pension, free life assurance, four weeks' holiday and generous removal and relocation expenses.

If you meet our requirements, please write or 'phone in complete confidence for additional information and an application form:

A. E. F. Chandler, M.A., Ph.D., D.I.C., M.I.Biol.,
Talentmark Limited, King House,
5/11 Westbourne Grove, London W2 4UA.

Biomedical and Scientific Consultants

1823

RESEARCH TECHNICIAN

required for research haematology laboratory. B.Sc., or equivalent. Whitley Council Scales and Conditions. Applications in writing enclosing curriculum vitae to the Secretary, University College Hospital Medical School, University Street, London WC1E 6JJ quoting reference HAEM/R.T. (1817)

UNIVERSITY OF OXFORD
INORGANIC CHEMISTRY LABORATORY
Post-doctoral Research Assistantship

Applications are invited for an S.R.C.-supported post from physical or inorganic chemists with an interest in biochemistry or biochemists with a strong physical bias to work with Dr. H. A. O. Hill (in collaboration with Dr. R. Ambler) on the structure and function of some metalloproteins, initially the plastocyanins, by n.m.r. spectroscopy and allied techniques.

The appointment would be for one year in the first instance, renewable for a second year, beginning on October 1, 1974. Starting salary according to age within the range £1,821, age 24, to £2,058, age 26, with F.S.S.U. membership.

Applications, with a **curriculum vitae** and the names of two referees, should be sent as soon as possible to the Administrator, Inorganic Chemistry Laboratory, South Parks Road, Oxford. Preliminary enquiries should be sent to Dr. Hill at the same address. (1861)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF PLANT SCIENCES

Applications are invited for a post of RESEARCH ASSISTANT in PLANT PHYSIOLOGY which is sponsored by the A.R.C. for work on the potential of C4 photosynthesis in crops of maritime temperate regions. The appointment will be made for one year in the first instance with possible renewal for a further period of two years. Salary on the scale £1,449 to £1,692 plus superannuation.

Applications together with the names of two referees should be sent to Professor H. W. Woolhouse, Department of Plant Sciences (Baines Wing), University of Leeds, Leeds LS2 9JT, by May 24, 1974. (1862)

AGRICULTURAL RESEARCH INSTITUTE OF NORTHERN IRELAND
HILLSBOROUGH CO DOWN

Assistant Experimental Officer

Applications are invited for the post of Assistant Experimental Officer to assist with experimental work with beef animals.

Salary scale:- £1,435 – £2,329 plus Superannuation Allowance.

Candidates should possess—a pass degree; H.N.D.; or O.N.D. in Agriculture, or equivalent.

Previous experience of supervisory duties and working with animals would be an advantage.

Application forms and further particulars may be obtained from the Secretary to whom applications should be submitted by Wednesday, 5th June, 1974.

Canvassing will disqualify. (1847)

LIVERPOOL POLYTECHNIC

Department of Chemistry

LECTURER II in CHEMICAL PROCESSING/ or INDUSTRIAL CHEMISTRY

Applications are invited for the appointment of a chemical engineer or chemist to join a team involved in the teaching and development of Industrial Chemistry to honours degree level. The successful candidate will have a first or higher degree in chemical engineering or chemistry and the necessary experience of semi-technical scale plant to exploit fully the extensive facilities in the recently completed Industrial Chemistry Block. Research and consultancy will be encouraged.

SALARY: £2700 — £3474 per annum

Application forms available from Staff Officer, E.C.N. Dept., Liverpool Polytechnic, Richmond House, Rumford Place, Liverpool L3 9RH. (1905)

FLINDERS UNIVERSITY OF SOUTH AUSTRALIA

School of Medicine

LECTURERS IN CLINICAL BIOCHEMISTRY, HUMAN MORPHOLOGY AND HUMAN PHYSIOLOGY

Applications are invited for lectureships in the new School of Medicine currently being established in Adelaide at the Flinders University of South Australia in each of the following fields:

Clinical Biochemistry, Human Morphology and Human Physiology.

The School of Medicine will form an integral part of the Flinders Medical Centre, a 710 bed teaching hospital located on campus. The first medical students began their course this year and will enter the Centre in February 1975. It is anticipated that appointees will take up their positions by October 1974 in order to help plan the integrated curriculum.

Suitably qualified appointees will have responsibility in the areas of teaching, research and clinical service. Lecturers with medical qualifications registrable in South Australia will receive a clinical loading, the amount depending on their qualifications and the degree of clinical responsibility undertaken.

Salary Scales: $A8,698 — $A11,982

Further information about the positions, including conditions of appointment and details required of applicants, may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications should be lodged, **in duplicate,** with the Registrar, The Flinders University of South Australia, Bedford Park, South Australia, 5042 by **June 7, 1974.** (1868)

CHAIRMAN DEPARTMENT OF APPLIED PHARMACOLOGY

Applications are invited for this position at the School of Pharmacy, Hebrew University of Jerusalem, Israel.

The Chairman will be responsible for all administrative and academic activities of the department in its new facility, a part of the Hebrew University Hadassah Medical Center.

Applications giving a complete curriculum vitae should be sent by August 1 to A. Kreiser, Associate Dean, School of Pharmacy, Hebrew University, P.O.B. 12065, Jerusalem, Israel. (1879)

SHEFFIELD AREA
HEALTH AUTHORITY (TEACHING)
CENTRAL DISTRICT (TEACHING)
Group Department of Haematology

NON-MEDICAL SCIENTIFIC OFFICER (BASIC GRADE)

Applications are invited for the above post from candidates possessing an appropriate 1st or 2nd Class Honours Degree. The successful applicant will be required to work in the hospital's Blood Transfusion Laboratories. Previous experience in Blood Transfusion work is not required.

Candidates wishing to view the laboratories should telephone Mrs. M. S. Lepp, Principal Non-Medical Scientific Officer, Royal Infirmary, Sheffield S6 3DA (Telephone 0742-20977 Ext. 258).

Whitley Council Terms and Conditions of Service apply—Salary Scale: £1,953-£2,694 p.a.

Applications stating age, qualifications, experience and the names and addresses of two referees to the District Administrator, Sheffield Area Health Authority (Teaching), Central District (Teaching), 10 Beech Hill Road, Sheffield S10 2RZ by 25th May 1974. (1859)

UNIVERSITY OF SASKATCHEWAN
Saskatoon, Canada
DEPARTMENT OF MECHANICAL ENGINEERING
ASSISTANT OR ASSOCIATE PROFESSOR: MATERIALS AND METALLURGY

A vacancy exists for an Assistant or Associate Professor to teach and conduct research in the area of materials and metallurgy within the Department of Mechanical Engineering. The appointee would be expected to work as a member of the group headed by Professor I. Le May and involved in the study of aspects of mechanical metallurgy. The successful applicant should have specific interests in the mechanisms and mechanics of fracture, and in relationships between mechanical properties and microstructure. Experience in fractography and transmission electron microscopy is desirable.

Applicants, having a Ph.D. Degree and experience as outlined above, should submit applications together with the names of three referees to Dr. P. N. Nikiforuk, Dean, College of Engineering, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 0W0.

The present salary scales, which are under review, are $12,000 to $15,600 for an Assistant Professor, and $15,750 to $20,300 for an Associate Professor. (1835)

TEXAS A & M UNIVERSITY
GRADUATE RESEARCH ASSISTANT

sought to assist in the study of the crystallographic phase problem through
BINARY INTEGER LINEAR PROGRAMMING TECHNIQUES

Applicants must intend to pursue graduate study in the fields of Computing Science or Operations Research. Interactive graphics display experience a plus. Stipend $350 to $375 monthly (half time)—resident rates on tuition available. Apply to Dr. Edgar F. Meyer, Dept. of Biochemistry & Biophysics, Texas A & M University, College Station, Texas 77843 USA or telephone (713) 845-1744. (1840)

UNIVERSITY OF GLASGOW
DEPARTMENTS OF BIOCHEMISTRY AND VIROLOGY
RESEARCH ASSISTANT

Applications are invited for a Research Assistant to work with Dr. C. A. Fewson and Dr. D. A. Ritchie on the genetic analysis of the bacterium **Acinetobacter calcoaceticus.** This study is part of an overall project on the regulation of metabolism in this organism.

Applicants must have an Honours degree with a suitable background in genetics, microbiology or molecular biology. The appointment, starting October 1, 1974, will be for one year initially and at a starting salary of up to £1,400 per annum. F.S.S.U.

Applications, with the names of two referees, should be sent to Dr. C. A. Fewson, Institute of Biochemistry, University of Glasgow, Glasgow G12 8QQ, as soon as possible. (1841)

MONASH UNIVERSITY
Melbourne, Australia
DEPARTMENT OF CHEMISTRY
SENIOR TEACHING FELLOW

Applications are invited from graduates whose previous experience and qualifications are appropriate to teaching organic chemistry and who should normally have completed a Ph.D. degree. The appointee will be expected to undertake research in addition to his teaching duties.

Salary Range: $A7,270 to $A8,698 per annum with superannuation based on an endowment assurance scheme, the employee and employer contributing 5% and 10% respectively.

Benefits: Travelling expenses for appointee and family, removal allowance, temporary housing for an initial period, repatriation after three years' service if desired.

Further general information and details of application procedure are available from the Academic Registrar, Monash University, Wellington Road, Clayton, Victoria 3168, Australia or the Secretary-General, Association of Commonwealth Universities (Apots), 36 Gordon Square, London WC1H 0PF. Enquiries about the Department to the Chairman, Professor R. D. Brown in the University.

Closing date: **June 11, 1974.**

The University reserves the right to make no appointment or to appoint by invitation. (1850)

TECHNICIAN
(QUALIFIED)

required for work in immunology in relation to renal disease. Experience in this field is not essential. Apply in writing, stating age and giving details of education and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. R.U.2. (1854)

UNIVERSITY COLLEGE OF WALES
WELSH PLANT BREEDING STATION

APPOINTMENT OF BIOCHEMIST

Applications are invited for a Biochemist to join a team working on the regulation of photosynthesis and utilisation of photosynthetic products in forage plants with particular reference to their potential for genetic improvement.

Initially the post would be concerned with investigations on the pool sizes and metabolic fates of photosynthetic intermediates, but would also be linked to current studies on enzyme regulation in leaves.

Applicants should have post-graduate research experience in the general area of carbohydrate metabolism.

The appointment will be made at the Higher Scientific Officer/Senior Scientific Officer level in the salary range £2,221 to £3,895. The post is superannuable under F.S.S.U.

Applications should be made by letter, together with the names of two referees, and should be sent to the Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Nr. Aberystwyth, Cards. SY23 3EB, on or before May 24, 1974. (1853)

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF CHEMISTRY

Post-doctoral Research Appointments

BIO-ORGANIC CHEMIST

Applications are invited for an S.R.C. Post-doctoral award to work with Dr. B. W. Bycroft on the Chemistry and bio-chemistry of Peptide Antibiotics.

Candidates should have an interest in, and preferably experience of, biological chemistry. The appointment is tenable for two years, commencing October 1, 1974 with a salary in the range of £2,118 to £2,412 with F.S.S.U.

Application forms and further details from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham. Closing date: May 27, 1974. Ref. No. 368. (1857)

THE EDINBURGH SCHOOL
OF AGRICULTURE

RESEARCH ASSISTANT

Applications are invited for a research assistantship for work on animal behaviour under the direction of Dr. D. G. M. Wood-Gush. The work will be exclusively with pigs.

Salary: £1,500.

Further particulars and application form from the Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (1786)

DEPARTMENT OF KINESIOLOGY
SIMON FRASER UNIVERSITY

ACADEMIC PHYSICIAN

An appointment of a physician with a well-developed research interest in any aspect of human physiology, bioengineering, prosthetics or human factors is offered in the Department of Kinesiology. The appointee will be required to work in an interdisciplinary environment with biochemists, engineers, work physiologists or biomechanics faculty, in a department which has growing graduate and undergraduate degree programmes.

Although the University itself does not have a medical faculty, the appointee will be encouraged to maintain and develop his clinical interests with the Faculty of Medicine at a nearby university and local hospitals. For suitably qualified applicants the possibility exists of a joint appointment with the Computing Science Department. The appointment will be made at either the assistant or associate professor level, depending upon qualifications. Salary negotiable.

Applications, together with three references, to:

Dr. E. W. Banister
Department of Kinesiology
Simon Fraser University.
BURNABY V5A1S6 British Columbia
(from whom further details can be obtained).
(1864)

CENTRAL PUBLIC HEALTH LABORATORY

TECHNICIAN

required by the Salmonella and Shigella Reference Laboratory. Suitable qualifications would be a relevant scientific degree; A.I.M.L.T. or H.N.C. in Medical Laboratory Sciences. This is the National Salmonella and Shigella Centre for Great Britain and the Commonwealth and offers training in the most advanced methods of Salmonella and Shigella identification.

Written applications with full details of age, experience and qualifications to the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (1730)

UNIVERSITY HOSPITAL OF WALES, HEATH PARK, CARDIFF
DEPARTMENT OF MEDICAL BIOCHEMISTRY

BIOCHEMIST OR SENIOR BIOCHEMIST

Applications are invited from suitably qualified candidates for this position in the Supra Regional Assay Laboratory for Polypeptide. The laboratory provides in association with other laboratories a diagnostic service using the technique of radioimmunoassay for centres throughout England and Wales.

The successful applicant will be expected to set up a computer based data handling and record system. He will also be responsible for the development and introduction of new assays. Opportunities exist for further training in hospital biochemistry leading to the qualification of Master of **Clinical Biochemistry**. Whitley Council conditions apply

Application forms available from the Personnel Department at the above hospital, to be returned by 7th June 1974, and further details may be obtained from Dr. G M Addison (0222 755944 Ext. 2811/2196) (1924)

Glaxo

HNC or HND in Chemistry

Ulverston

We have vacancies for Technical Officers or Laboratory Assistants with laboratory experience of organic chemistry at our plant at Ulverston, which is situated on the shores of Morecambe Bay and on the southern fringe of the Lake District National Park.

You will join an established group in the Chemical Process Development department working on a variety of problems connected with antibiotics manufacture. This work will include plant troubleshooting, pilot plant operations, process development, and applied research, and will be particularly suitable to practically-oriented people who have recently gained an HNC or HND qualification, or are engaged upon such courses. Every encouragement will be given to those wishing to continue their studies.

The starting salary will be according to experience, age and qualifications. The company offers good conditions of service including bonus, pension and sick pay schemes.

Please apply in writing, quoting reference U.530, to:
Personnel Officer (JE),
Glaxo Laboratories Limited,
North Lonsdale Road,
Ulverston. (1921)

SHEFFIELD AREA
HEALTH AUTHORITY (TEACHING)
CENTRAL DISTRICT (TEACHING)

SENIOR SCIENTIFIC OFFICER
SCIENTIFIC OFFICER

A vacancy exists within the Sheffield Supra-Regional Endocrine Investigation Centre for a Senior or Basic Grade non-medical Scientific Officer, to commence as soon as possible after 14th June 1974.

The post will be of great interest to graduates with a first or second class honours degree or higher qualification with a background of medical physics and/ or biochemistry.

The person appointed will be expected to aid the development of automated techniques and to help in the every-day maintenance of complex electronic equipment including a 16 K-store computer. The ability to write programmes and/or the will to learn would be advantageous.

Whitley Council Terms and Conditions of Service apply.

Salary Scales:
Basic Grade—£1,953 to £2,694 p.a.
Senior Scientific Officer—£2,964 to £3,843 p.a.

Candidates wishing to view the laboratories should telephone Mr. B. Bevan, Principal Non-Medical Biochemist, Jessop Hospital for Women, Sheffield. (Telephone 0742 29291 ext. 269)

Applications stating age, qualifications, experience and the names and addresses of 2 referees to the District Administrator, Central District (Teaching), Sheffield Area Health Authority (Teaching), 10 Beech Hill Road, Sheffield S10 2RZ, by 25th May 1974. (1860)

A.S.P. BIOLOGICAL AND MEDICAL PRESS (Elsevier division)

(Publishers of the International Biochemical Journal **Biochimica et Biophysica Acta**) has immediate openings in AMSTERDAM for full-time

editorial assistants

Description

- Preparation of manuscripts for printing
- Correction of proofs
- Language correction of contributions written by non-English speaking authors
- Supervision of free-lance workers
- Responsible and variable work

Requirements

- Degree, or equivalent, in chemistry, biochemistry or biomedicine preferred
- English mother tongue

A good salary, according to qualifications and experience, work in a congenial atmosphere and excellent social security arrangements are offered.

Handwritten applications, giving details of education and previous experience and an indication of salary expected, should be addressed to:

The Personnel Department
Associated Scientific Publishers
P.O. Box 2400, Amsterdam, The Netherlands.

(1944)

UWIST CARDIFF
University of Wales Institute of Science and Technology

RESEARCH ASSOCIATE APPLIED PHYSICS

with good Honours degree in relevant subject and Ph.D. or equivalent—required to work on the transport theory of tunnelling and its application to semiconductor devices problems.

Salary:
1st year, £1,929: 2nd year, £2,058 (under review), with FSSU

Requests (quoting Ref. N) for details and application form (returnable by June 7, 1974) to Personnel Section, UWIST, Cardiff CF1 3NU. (1855)

McGILL UNIVERSITY
MONTREAL, QUEBEC, CANADA

Applications are invited for a two year appointment at the Assistant or Associate Professor level for a biologist-physiologist with strong BIO-MATHEMATICAL interests in the Department of PHYSIOLOGY starting September 1, 1974. The department hopes to be able to extend the appointment. Responsibilities include teaching undergraduate and graduate level Science courses. Send applications with curriculum vitae and names of 3 references to:

Ms. Maria Olejar
Dept. of Physiology
3655 Drummond Street
McGill University
Montreal, Quebec, H3G 1Y6, Canada (1779)

UNIVERSITY OF BIRMINGHAM
BRITISH HEART FOUNDATION CHAIR OF CARDIOLOGY

Applications are invited for the British Heart Foundation Chair of Cardiology in the Department of Medicine. Appointment from a date to be arranged.

Salary in the clinical professorial range, maximum £7,599.

Further particulars obtainable from the Registrar, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (12 copies: one from overseas applicants) naming 3 referees, should be sent by June 17, 1974. (1742)

UNIVERSITY OF BIRMINGHAM
CHARLES HAYWARD CHAIR OF GERIATRIC MEDICINE

Applications are invited for the newly established Charles Hayward Chair of Geriatric Medicine in the Department of Medicine. Appointment from a date to be arranged.

Salary in the clinical professorial range, maximum £7,599.

Further particulars obtainable from the Registrar, University of Birmingham P.O. Box 363, Birmingham B15 2TT, to whom applications (12 copies: one from overseas applicants) naming 3 referees, should be sent by June 17, 1974. (1741)

UNIVERSITY OF SYDNEY
DEPARTMENT OF THEORETICAL CHEMISTRY

Professional Officer Grade I (Electron Spectroscopist)

Applications are invited from candidates with Ph.D. or equivalent qualification in Chemistry or Physics.

Salary up to $A7,857 per annum.

The appointment is initially for one year, renewable annually subject to mutual agreement for a period of three years.

Experience in experimental photoelectron spectroscopy or in a closely related field is essential. The appointee will take overall responsibility for maintaining and organizing the use of the equipment (at present, a Perkin-Elmer PS-18 spectrometer) and will take an active part in the design of new instrumentation. A suitable candidate will be encouraged to participate in the research programme of the Department.

Applications, including details of qualifications and experience and names of two referees, to the Registrar, University of Sydney, N.S.W., 2006, Australia. Further information from Professor N. S. Hush, School of Chemistry, University of Sydney. (1930)

university of wales

university college of swansea

Applications are invited for the following:

Postdoctoral Research Assistant

A Postdoctoral Research Assistant is required in the Department of Biochemistry to work on an S.R.C. sponsored research programme concerned with enzymic mechanisms involved in the formation of uracilyl amino acids. Preference will be given to applicants with experience in the separation and purification of enzymes, especially those of plants.

The commencing salary will be on the scale £2,118 to £2,412 per annum plus F.S.S.U. benefits, and the appointment will be for one year in the first instance from August 1, 1974, renewable annually up to December 31, 1976.

The closing date is **Friday, June 14, 1974.**

Department of Genetics

Research Studentship

The Medical Research Council is prepared this year to offer to a suitable candidate a research studentship tenable at the above University College. The Research will involve the study of mechanisms of genetic change and effects of environmental mutagens in yeast under the supervision of Dr. J. M. Parry. Applicants should have a first or upper second class degree in a biological subject.

The closing date is **Friday, June 7, 1974.**

Further particulars and application forms may be obtained from the Registrar/Secretary, University College of Swansea, Singleton Park, Swansea, SA2 8PP, to whom they should be returned by the appropriate date. (1884)

UNIVERSITY OF ABERDEEN
Senior Lectureship in Medical Physics

Applications are invited from experienced radioisotope hospital physicists to be responsible for team of physicists, technicians and ancillary staff engaged in wide range of research activities and providing nuclear medicine service to the Hospital Region. The successful candidate will also be responsible for team providing D.M.R.I physics course, and join in M.Sc. (Medical Physics) teaching. Salary on scale £4,368 to £5,496 rising to £4,707 to £5,844 at October 1, 1974, with initial placing according to qualifications and experience.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by May 31, 1974. (1880)

UNIVERSITY OF ABERDEEN
Research Assistant in Zoology

Applications are invited for above post for work on social behaviour and population ecology of shelduck at Culterty Field Station. Applicants should have a good degree in Zoology including courses in behaviour and ecology. Post is financed by N.E.R.C. for three years from October 1, 1974. Salary within range £1,305 by 87 to £1,659.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by May 25, 1974. (1877)

Microbiologist

A vacancy has arisen within our expanding organisation at Havant, Hants, for a Microbiologist to join a small team involved in the microbiological quality control of pharmaceutical nutritional products

The candidate should have a degree or equivalent qualifications in microbiology, age 25/45 and have at least two years experience.

A competitive salary will be paid depending upon age and experience.

The Company offers a non-contributory Pension and Life Assurance Scheme. Assistance with re-location expenses will be considered.

Please apply in writing to:-

Cameron Wolstenholme,
Director of Personnel & Industrial Relations,
John Wyeth & Brother Limited,
Huntercombe Lane South,
Taplow,
Maidenhead,
Berks, SL6 0PH. (1886)

Wyeth

ICI

CORPORATE LABORATORY-RUNCORN

The Corporate Laboratory at Runcorn has a vacancy for a

CELL PHYSIOLOGIST

with research experience in the culture **in vitro** of animal cells and in the study of the characteristic properties and functions of such cells. Applicants should be under 30 and hold a PhD in this field.

The successful applicant would join a multidisciplinary team engaged in long-term research in the Biosciences. While the team has a defined need for specialist skills in cell physiology, the successful applicant would be given every encouragement to initiate original research projects.

Runcorn, conveniently situated for Manchester, Liverpool and Chester, is within easy reach of the Lake District, North Wales and the Peak District, yet is only 2½ hours by train from London.

If you are interested, please write for an application form to:

Mr J. A. Hurst, Personnel Officer,
ICI Limited, Corporate Laboratory,
P.O. Box 11,
The Heath, Runcorn, Cheshire. WA7 4QE.

(1939)

GRASSLAND RESEARCH INSTITUTE
Hurley, Maidenhead, Berkshire

An opportunity exists for a HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER to join a small group of scientists engaged in operational research on grassland farming enterprises with special reference to permanent grassland. Applicants should have a knowledge of farming systems and preference will be given to candidates with experience, or a special interest in developing methods of analysing the physical and socio-economic data being collected by the group.

Candidates should have a good honours degree in an appropriate subject, with at least two years post qualifying experience for appointment at H.S.O. (£2,221 to £2,854), and four years for S.S.O. (£2,798 to £3,895). Commencing salary according to qualifications and experience.

Superannuation under F.S.S.U. with a non-pensionable allowance to offset personal contributions.

Applications to the Secretary by June 7, 1974 giving curriculum vitae and the names of three referees and quoting Reference 10/G/16. (1934)

BIO-RESEARCH LABORATORIES LTD.
CANADA

Applications are invited from qualified Veterinary Pathologists interested in joining the Department of Toxicology in the capacity of Staff Pathologist. Responsibilities will include technical supervision of Autopsy Room and Histology Laboratory personnel and activities. Principally, however, the successful candidate will be responsible for the evaluation of histological specimen material arising out of toxicological research in a variety of laboratory animal species and for the preparation of reports appropriate to the research in question. Salary will be commensurate with qualifications and experience.

Bio-Research Laboratories Ltd is a Canadian research company operating in the life sciences field. Applications, curricula vitarum and requests for further details may be directed to Dr. C. I. Chappel, Director, Bio-Research Laboratories Ltd., 265 Hymus Blvd, Pointe Claire, Quebec, Canada H9R 1G6. (1799)

Theoretical Nuclear Physicists

are required to join a newly formed group at the Daresbury Laboratory. Theoreticians will be expected to collaborate with University Physicists in developing research programmes for the large tandem Van de Graaff accelerator (terminal potential 30 MV) being built at the Laboratory. Preference will be given to theoreticians interested in heavy ion reactions and the structure of heavy nuclei. Posts are normally available for a fixed term of three years.

The successful applicants will be appointed as Research Associates at salaries between £2,096 and £4,898. The level at which an Associate is appointed is dependent on age, ability and experience.
Applicants should possess a Ph.D or its equivalent, or expect to obtain their Ph.D during 1974. Superannuation is contributory under the Federated Superannuation System for Universities. Closing date: 24 May 1974.

Please write or telephone Warrington 65000, Ext 467, for an applicotion quoting reference DL/508/T to:

(1848)

SCIENCE RESEARCH COUNCIL — DARESBURY LABORATORY

**Personnel Officer,
Science Research Council
Daresbury Laboratory,
Daresbury,
Warrington WA4 4AD.**

WESSEX WATER AUTHORITY
Somerset Rivers Division

Assistant Biologist

With the agreement of the Water Services Staff Commission, applications are invited for the above post from persons at present employed in the Water Industry as defined by Circular 5/73 as amended by 8/73. First consideration will be given to applicants from within the Authority's Region.

This post is suitable for a young qualified limnologist wishing to gain experience.

The successful candidate will work under the direction of the Water Quality Officer. He will be involved in the sampling of Rivers, both chemically and biologically. An interest in instrumentation is desirable.

Commencing salary for the post will be within the range £1,353 to £1,926 per annum.

Job specification and application forms (which should be returned not later than 3rd June) may be obtained by writing to:-

Wessex Water

**Divisional Manager,
Somerset Rivers Division,
Wessex Water Authority,
The Watergate,
West Quay,
Bridgwater, Somerset TA6 3HN.**

(1918)

The Hatfield Polytechnic

DEPARTMENT OF BIOLOGICAL SCIENCES

Laboratory Superintendent

Applications are invited from suitably qualified and experienced technicians for this new post in the Department of Biological Sciences.

A high level of technical skills is required together with proven supervisory and organisational ability.

Salary scale T6 £2,235–£2,535 per annum.

Application forms may be obtained from the Staffing Officer, The Hatfield Polytechnic, PO Box 109, Hatfield, Herts. Telephone 68100, ext. 309. For further information please contact Mr K. Thomas, Head of Department, ext. 247. This advertisement appears with the approval of the Local Government Staff Commission. Please quote ref: 472.

(1920)

UNIVERSITY COLLEGE CARDIFF
DEPARTMENT OF BIOCHEMISTRY

Two 3-year research assistantships are available for stulies on:

(1) Control of protein catabolism (with Dr. J. Kay) starting from July 1 or as soon as possible thereafter. Experience in peptides and enzyme chemistry and in the operation of amino acid analysers would be advantageous but not essential.

(2) Lipid synthesis and its control in plants (with Dr. J. Harwood) starting on October 1. Experience in enzymology would be advantageous.

Applicants should possess a B.Sc. or similar qualification and have a good knowledge of basic biochemical techniques. Starting salaries in range £1,416 to £1,563 per annum (under review).

Further particulars available from Dr. Kay and Dr. Harwood, c/o Biochemistry Department.

Applications including a curriculum vitae and the names and addresses of 2 referees should be sent to: The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL, no later than May 31, 1974. Please quote 0556. (1876)

ST. HELIER HOSPITAL
Carshalton, Surrey

A BASIC GRADE BIOCHEMIST

is required for a busy Clinical Chemistry department in the above hospital. The Department is highly automated with an SMA 12.60, etc., and undertakes a wide variety of work.

Previous experience in radioimmunoassay techniques desirable but not essential.

Applications, giving details of qualifications, experience and the names and addresses of two referees, should be sent to Dr. L. Chapman immediately. (1874)

LAURENTIAN UNIVERSITY
Sudbury, Ontario, Canada

Applications are invited for a faculty position at the rank of Assistant Professor in the Department of Biology. This is a temporary (sessional) appointment, for one year in the first instance.

Candidates should possess a doctorate and preferably be bilingual (English and French). A Zoologist is being sought to teach vertebrate biology-systematics and embryology to undergraduates.

Availability for appointment: September 1, 1974.

Closing date for receipt of applications: When a suitable candidate is selected.

Replies containing curriculum vitae, list of publications and the names of three referees should be forwarded to:

Chairman,
Department of Biology,
Laurentian University,
Sudbury, Ontario,
Canada P3E 2C6. (1878)

UNIVERSITY OF LIVERPOOL
Chair of Clinical Pharmacology

Applications are invited for the Chair of Clinical Pharmacology which will become vacant on September 30, 1974, following the retirement of Professor A. Wilson.

The salary of the Professor will be within the range approved for clinical Professorial salaries and initially will depend on the qualifications and experience of the successful candidate.

Applications (16 copies), together with the names of three referees, should be received not later than June 3, 1974 by the undersigned, from whom further particulars may be obtained. (Candidates overseas may send one copy only, by airmail). Quote ref. RV/N/276015.

H. H. Burchnall,
Registrar,
The University,
P.O. Box 147,
Liverpool L69 3BX. (1872)

WYE COLLEGE
(University of London)
DEPARTMENT OF PHYSICAL SCIENCES

POST-GRADUATE ASSISTANTSHIP

Applications are invited for an Agricultural Research Council three-year Post-graduate Assistantship to study the biophysical action of plant growth-regulating substances on roots and root membranes.

Applicants should be graduates with special interests in physical chemistry and those expecting to graduate this summer may apply. The Assistant may be allowed to register for a higher degree.

Applications with the names of two referees should be sent to the Secretary (N), Wye College, Wye, Ashford, Kent, from whom further particulars can be obtained. (1870)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF ELECTRONIC AND ELECTRICAL ENGINEERING

RESEARCH IN UNDERWATER ACOUSTICS

Applications are invited for the following posts:

Senior Research Associate

The Department has been awarded a three-year contract by the Ministry of Defence (Navy) to investigate various means of detecting acoustically objects buried in sediments. Applicants should be graduate electronic engineers with suitable post-graduate experience. An appointment can be made immediately.

Senior Research Associate/ Research Associate

The Science Research Council has awarded the Department a three-year research grant to study and optimise high frequency underwater acoustic transducer performance. Applicants should be graduates in either electronic engineering, electrical engineering, physics or mechanical engineering.

The appointment may be at the level of Research Associate or Senior Research Associate, depending upon qualifications and experience, and can commence on July 1, 1974, or as soon after as is possible.

Salary scales: (under review).

Senior Research Associate £2,223 to £3,048 (exceptionally £4,548)

Research Associate £1,569 to £2,223 (exceptionally £2,718)

Plus F.S.S.U.

Appointees wil join an active research team working in Underwater Acoustics and Underwater Technology. Previous experience in Underwater Acoustics is not essential.

Applications (3 copies) with names of 3 referees to Assistant Registrar (S), University of Birmingham, P.O. Box 363, Birmingham B15 2TT by May 31, 1974. Please quote reference: NR5. (1873)

ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH

Graduate as Technician required for Cytogenetics Unit. Previous experience in cytogenetics and tissue culture an advantage but not essential as full training can be given.

Post would be suitable for new graduate wishing to make a career in cytogenetics. A suitable qualified appointee may be eligible for promotion to full graduate status should such a vacancy occur within the Unit.

Applications, giving the names of two referees, to the Sector Administrator, Royal Hospital for Sick Children, 1 Rillbank Terrace, Edinburgh EH9 1LN. (1867)

UNIVERSITY OF RHODESIA
DEPARTMENT OF GEOGRAPHY

SENIOR LECTURESHIPS/ LECTURESHIPS IN GEOGRAPHY
(TWO VACANCIES)

Following on recent additions to staff establishment, the Department will consider applications from geographers with a variety of topical interests, both human and physical. Applicants should indicate in their applications the full range of their interests and abilities as well as their special field of study.

Salary scales (approximate Sterling equivalents): Senior Lecturer £5,346 by £214 to £7,058; Lecturer Grade I £4,857 by £180 to £5,577; Lecturer Grade II £2,994 by £154 to £3,456 by £171 to £3,798 by £180 to £4,518 by £170 to £4,688.

Family passage and allowance for transport of effects on appointment. Assistance with accommodation for up to three years for persons recruited from outside Rhodesia. Sabbatical and triennial visits with travel allowance. Superannuation and medical aid scheme.

Applications (six copies) giving full personal particulars (including full names, place and date of birth, etc.), qualifications, experience and publications and naming three referees, should be submitted by **June 15, 1974** to the Registrar, University of Rhodesia, P.O. Box 2702, Salisbury, Rhodesia. An additional copy should be sent to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London, W.C.1, from whom further particulars may be obtained.

The Head of Dept. Professor G. Kay is at present in the United Kingdom and can be contacted through the Association of Commonwealth Universities. (1869)

Universiteit van Amsterdam

Applications are invited for a teaching and research post (lecturer) in the Department of Structural Geology. Duties will include instruction in structural geology and in fieldwork. Applicants should have considerable experience in structural geology. Experience in petrology or mineralisation problems would be favourable. Salary in accordance with background and experience.

Send curriculum vitae, precise research interests and names of at least two referees to: Dr. O. J. Simon, Geological Institute, 130 Nieuwe Prinsengracht, Amsterdam, The Netherlands.

(1871)

UNIVERSITY OF OXFORD
DEPARTMENT OF BIOCHEMISTRY

M.R.C. IMMUNOCHEMISTRY UNIT

A vacancy exists for a Junior Technical Officer/ Technical Officer in the above unit. Applicants should be qualified to Higher National Certificate standard and have several years' experience in biochemical/analytical techniques, including spectrophotometry, chromatography and radiochemistry. Some knowledge of protein chemistry and an ability to work with small animals is desirable, but not essential.

Salary, according to age and experience, on the scale £1,854 to £2,073 (bar) £2,184 to £3,057 (under review. Applications, including full details of education and career to date, and the names of two referees, to: The Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU. (1891)

SENIOR BIOCHEMIST
WESTERN INFIRMARY AND GARTNAVEL GENERAL HOSPITAL
Glasgow
(DEPARTMENT OF BIOCHEMISTRY)

The successful applicant for the above position will have the opportunity to gain extensive experience of automation or, alternatively, take part in specialist developments with this expanding department.

The Laboratories are a part of the Department of Pathological Biochemistry of the University of Glasgow, and therefore experience gained in an academic environment will be regarded as advantageous. The main Laboratories are situated in the recently opened Gartnavel General Hospital, and deal with the majority of the biochemical analyses for the Western District of Glasgow.

Potential applicants are invited to visit the Laboratories by appointment (Tel: 041-334 8122).

Applications stating age, experience, qualifications etc., together with the names of two referees should be sent to Dr. J. T. Robson, Department of Biochemistry, Gartnavel General Hospital, Great Western Road, Glasgow G12 0YN. (1916)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE
(University of London)
KEPPEL STREET, WC1E 7HT

RESEARCH ASSISTANT experienced in Biochemistry is required for the Hepatitis Reesarch Unit (Professor A. J. Zuckerman). Salary up to £2,073 per annum plus £126 London Weighting. Written applications to Secretary (A1), London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT. (1889)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF ORGANIC CHEMISTRY

Applications are invited from suitably qualified organic and biochemists for a Senior Research Assistantship. The person appointed would be expected to work on the biosynthesis of fungal metabolites from ^{13}C-precursors. The appointment will date from October 1, 1974 and the salary will be in the range £1,959 to £2,178 per annum (under review) plus F.S.S.U. Applications giving full academic qualifications, details of research experience and names of two referees should be sent as soon as possible to the Registrar, The University of Liverpool, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/N/276019. (1910)

UNIVERSITY OF READING

The Ministry of Agriculture, Fisheries and Food is prepared this year to offer to a suitable candidate a Studentship tenable in the Department of Physiology and Biochemistry in the University of Reading. The value of the MAFF award in 1974 will normally be £695 per annum. The subject for research leading to a Higher Degree will be either, protein and amino acids in the growing rabbit or citrate and malate metabolism in the pregnant ewe. Work should start in October 1974 and applicants should hold at least an Upper Second Class degree in a suitable subject or hope to qualify this summer. Further particulars may be obtained from Professor C. Tyler, Department of Physiology and Biochemistry, The University, Whiteknights, Reading RG6 2AJ. Ref. M.N.18. (1890)

DALHOUSIE UNIVERSITY
Nova Scotia, Canada
DEPARTMENT OF ANATOMY

TWO ASSOCIATE OR ASSISTANT PROFESSORS

Applications are invited from persons with a Ph.D. or a professional qualification for the above positions. Duties may include the teaching of Anatomy to Medical, Dental or Paramedical students. An ability to teach gross anatomy and a research interest in the nervous system would be an advantage. Salary (minimum $15,000) and rank commensurate with experience. Applications together with curriculum vitae and the names of two referees should be addressed to Dr. D. G. Gwyn, Department of Anatomy, Dalhousie University, Halifax, Nova Scotia, Canada by June 20, 1974 (1881)

COMMONWEALTH AGRICULTURAL BUREAUX
Vacancy for
SCIENTIFIC INFORMATION OFFICER
at the
COMMONWEALTH BUREAU OF SOILS
Rothamsted Experimental Station
Harpenden, Hertfordshire

Duties: Preparing abstracts for the abstracting journal "Soils and Fertilizers", which covers world scientific literature on soils and soil-plant relationships, and dealing with scientific enquiries within these fields.

Qualifications: A degree in soils or in agricultural science, or in sciences basic to these. Ability to write good and concise English essential. The successful candidate may be required to learn a foreign language. Experience or training in information work, including subject indexing, would be an advantage.

Salary: In scale £1,435 to £2,592 (bar) £2,798 to £3,478 (bar) £3,756 to £4,004, plus a compensatory allowance (taxable but not superannuable) of 4½% to offset personal contribution to F.S.S.U. Starting salary according to qualifications, experience and age.

Application forms: and full particulars from the Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN

Closing date for applications: June 14, 1974. (1888)

CSIRO

DIVISION OF APPLIED ORGANIC CHEMISTRY

MELBOURNE VIC

RESEARCH FELLOWSHIP

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD ORGANIC CHEMISTRY

GENERAL: The Division undertakes research into a wide spectrum of applied chemical problems including problems associated with the chemistry of natural problems.

DUTIES: Research study of biologically active compounds from plant or animal sources and possibly on the metabolism of biologically active compounds in animals. The research background of the appointee may be taken into account in selecting the research project.

QUALIFICATIONS: A Ph.D. in organic chemistry or equivalent qualifications, together with demonstrable research ability.

SALARY: Appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: $A9,380 — $A14,290 p.a.

TENURE: This position is available for a fixed term of three years.

Applications stating full personal and professional details, the names of at least two professional referees and quoting Reference Number 586/181 should reach:-

The Personnel Officer,
Australian Scientific Liaison Office,
64–78 Kingsway,
LONDON WC2B 6BD.

by the 14th June, 1974.

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.

(1896)

SITUATION REQUIRED

Indian Agricultural Executive M.Sc. (Agriculture), forty years, with wide experience of Planning, Organising and Administration of Agricultural Projects, Sales and Sales promotion of Agricultural inputs, Farm Management, Agricultural Extension and research both in India and abroad seeks immediate assignment of two to four years residential tour. (1906)

RESEARCH UNIT requires an assistant who is interested in human genetics, to organise date and research projects relating to various aspects of the subject. Applicants should have experience in biomedical and/or secretarial work and be able to work on her own initiative. Please apply to the Administrative Secretary, Paediatric Research Unit, Guy's Hospital Medical School, London, SE1 9RT. (1927)

THE UNIVERSITY OF ASTON IN BIRMINGHAM

DEPARTMENT OF BIOLOGICAL SCIENCES

GENETICIST

Applications are invited from suitably qualified persons for a Lectureship. The responsibilities of the post will include the teaching of genetics and biometry to students of biological sciences and the biology of man and his environment. Appointment to commence from August 1, 1974.

Salary scale: Commencing salary in the range £1,929 to £2,388 per annum on a scale rising to £4,548 per annum (to be increased from October 1, 1974).

Requests for further details and application forms (which should be returned within 14 days of the appearance of this advertisement) should be sent, preferably on a postcard, quoting Ref. No. 972/6, to: Staff Officer, University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET. (1911)

COMMONWEALTH AGRICULTURAL BUREAUX

Vacancy for

SCIENTIFIC INFORMATION OFFICER

at the

COMMONWEALTH BUREAU OF ANIMAL BREEDING AND GENETICS, EDINBURGH

Duties include preparation and editing of abstracts for the journal "Animal Breeding Abstracts", indexing, information retrieval and dealing with enquiries.

Applicants must have a degree in the biological sciences or a degree in another subject plus experience of information work in a suitable animal science field, and a reading knowledge of one or more foreign languages.

Salary in scale £1,435 to £2,592 (bar) to £2,798 to £3,478 (bar) to £3,756 to £4,004 plus a compensatory allowance (taxable but not superannuable) of 4½% to offset personal contribution to F.S.S.U. Starting salary will be in the lower sector of the scale.

Application forms and full particulars from the Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN. Closing date for applications: June 15, 1974. (1887)

GREENWICH & BEXLEY AREA HEALTH AUTHORITY

BROOK GENERAL HOSPITAL

Senior Technician—Neuropathology

A vacancy exists in a new department which will deal with routine material from Neurosurgical and Neurological Units and research projects.

The person appointed will be jointly responsible for implementing the services of the department.

Applications giving age, experience and 2 referees to:

Senior Chief Technician,
Brook General Hospital,
Shooters Hill Road,
Woolwich, London SE18 4LW. (1885)

POST-DOCTORAL RESEARCH

Two-year Post-doctoral Research position available immediately to study biochemical aspects of growth control in normal and leukemic lymphocytes. Experience in isolation and characterisation of nuclear proteins or general training in biochemistry preferred.

Further inquiries and a curriculum vitae with the names of two references should be sent to:

Dr. William I. Waithe
Service d'immunologie
Centre hospitalier de l'Université Laval
2705 boulevard Laurier
Québec G1V 4G2
Canada. (1883)

UNIVERSITY OF SURREY

Guildford, Surrey GU2 5XH

DEPARTMENT OF CHEMISTRY

Applications are invited for a Science Research Council Postdoctoral Assistantship for work with Professor J. A. Elvidge and Dr. J. R. Jones on a study of tritium exchange in heterocyclic compounds. The appointment is available from 1/10/74 and will be for either one or two years. Salary £2,058 by £165 plus F.S.S.U. Applications together with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to one of the above-named persons. (1882)

CHELSEA COLLEGE
University of London

RESEARCH ASSISTANT—
ACTIVATION ANALYSIS—
GEOCHEMISTRY

Applications are invited from candidates with a first degree in Chemistry or Chemistry/Geology for a temporary RESEARCH ASSISTANTSHIP with a project (sponsored by N.E.R.C.) concerning the geochemistry of silicate melts. Work will entail activation analysis of rock and mineral samples and will be carried out at London University Reactor Centre, Ascot. Salary scale: £1,584 to £1,758 to £1,929 per annum. Superannuable. Further particulars and application forms from the Personnel Officer (N), Chelsea College, Manresa Road, London SW3 6LX. Closing date May 29, 1974.
(1907)

UNIVERSITY OF READING
Plant Science Laboratories
DEPARTMENT OF BOTANY

S.R.C./C.A.S.E. STUDENTSHIP
IN PHYTOCHEMISTRY

Applications are invited from Honours Graduates in Organic Chemistry, Biochemistry or Botany to work on "Comparative Aspects of Phytoalexin production in the family Leguminosae" in association with I.C.I. Plant Protection Ltd., Jealott's Hill Research Station, Bracknell, Berkshire.

The studentship is available from October 1, 1974 for a period of up to three years.

Application with a curriculum vitae and the names of two referees should be sent to:

Dr. J. B. Harborne,
Phytochemical Unit,
Plant Science Laboratories,
Whiteknights,
Reading RG6 2AS.

Closing date is June 15, 1974. (1897)

THEORISTS AT TRIUMF

Applications are invited for two positions to be filled on or after April 1, 1975. TRIUMF, a 500 MeV high intensity cyclotron, is operated on the University of British Columbia campus by a consortium of four universities.

Theoretical physicists will work closely with experimenters on problems of intermediate energy physics. Appointments initially for one year, will be renewable subject to availability of funds. Depending on experience, salary and rank will correspond to Assistant or Associate Professor.

Closing date is September 30, 1974. Send resume and references to:

Dr. J. R. Richardson, Director,
TRIUMF, University of British Columbia,
Vancouver V6T 1W5, B.C., Canada.
(1895)

UNIVERSITY OF KENTUCKY

ASSISTANT PROFESSOR
BIOCHEMISTRY

Several full-time faculty positions are available immediately for candidates committed to pursue fundamental research programmes in membrane biochemistry or molecular biology. Participation is expected in biochemistry courses for medical students, graduate students and undergraduates. Only candidates with post-doctoral experience will be considered. The University of Kentucky is an equal opportunity/affirmative action employer.

Send vita and three letters of reference to Chairman, Department of Biochemistry, College of Medicine, University of Kentucky, Lexington, Kentucky 40506. (1894)

UNIVERSITY OF BRISTOL
LONG ASHTON RESEARCH STATION

Applications are invited for a RESEARCH ASSISTANT to work on the promotion of flowering in Sitka Spruce. The work would be under the general direction of Dr. L. C. Luckwill and be carried out in collaboration with the Forestry Commission Northern Research Station at Roslin, near Edinburgh. Although based at Long Ashton the successful candidate would also be required to carry out field work in Scotland.

The assistantship is for a period of three years commencing in July 1974. Applicants should possess a good Honours degree in Botany, Applied Biology, Horticulture or Forestry and show a marked aptitude for applied research. Salary would be in the range £1,707 to £1,846 per annum. A current driving licence is essential.

Applications to: The Secretary, Research Station, Long Ashton, Bristol BS18 9AF, before June 14, from whom further particulars can be obtained.
(1893)

Scottish Health Service

COMMON SERVICES AGENCY

SCOTTISH BLOOD TRANSFUSION CENTRE

Applications are invited for the post of **PRINCIPAL SCIENTIFIC OFFICER** in the above Department. The successful applicant will be responsible to the Regional Director for the day to day management of the scientific, logistic and technical aspects of the Blood Bank and Blood Component Divisions in which 35 technical and scientific staff are employed.

The post is on the Principal Biochemist salary scale, and NHS terms and conditions of service will apply. Further particulars may be obtained from the National Administrator, Scottish Blood Transfusion Service, 17 Rothesay Terrace, Edinburgh EH3 7SF. Applications with the names of 2 referees should be forwarded to the Secretary, Common Services Agency for the Scottish Health Service, 17/18 Rothesay Terrace, Edinburgh EH3 7SF not later than 8th June, 1974.

(1935)

Reckitt & Colman

Dietician

To join the Medical Department of a well established and expanding Pharmaceutical Division of this major British Company.

The successful applicant will join a highly qualified team of experienced professionals and will provide his or her professional contribution on all subjects relating to nutrition. Initial work will be in the field of infant nutrition, particularly premature infants and neonates, and will involve liaison with clinical research workers in centres throughout the U.K.

The demands of this job will require the successful applicant to be well qualified and experienced, preferably with a research orientated career background which will enable him or her to function effectively in an atmosphere of new ideas and creative work.

The appointment is located in Hull and the salary will be attractive. Please write quoting ref U.75 for an application form to:

R. A. Sandow,
Divisional Personnel Manager,
Reckitt & Colman,
Pharmaceutical Division,
Dansom Lane, Hull HU8 7DS

(1940)

British Museum (Natural History)
Sub-department of Anthropology

Physical Anthropologist

■ **Develop and co-ordinate research on fossil and recent populations, in collaboration with Museum's Serological Unit ■ Curatorial responsibilities.**

☐ 1st/2nd hons degree in appropriate subject ☐ At least 2 years' postgraduate experience ☐ Age under 32 ☐ Appointment as Senior Scientific Officer (£2973-£4070) or Higher Scientific Officer (£2396-£3029) according to age and experience ☐ Salaries under review ☐ Ref: SB/23/DK.

☐ Application forms (for return by 10 June 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Department of Agriculture and Fisheries for Scotland
Agricultural Scientific Services, East Craigs, Edinburgh

Analytical Chemist

■ **Join small team analysing residues of pesticides and heavy metals in relation to agriculture, food storage, wildlife and environment generally ■ Development of new analytical methods involved ■ Chemotaxonomy of plants using modern analytical techniques.**

☐ Hons degree, or equivalent, in Chemistry ☐ Experience of gas chromatography and other microanalytical methods an advantage ☐ Age under 30 ☐ Appointment as Higher Scientific Officer (£2221-£2854) or Scientific Officer (£1435-£2329) according to age and experience ☐ Salaries under review ☐ Ref: SA/4/DLA.

☐ Application forms (for return by 10 June 1974) from Scottish Office, Personnel Division, Room 214, 22/25 Queen Street, Edinburgh, EH2 1LY, telephone 031-556 9222 ext. 762.

Department of Agriculture and Fisheries for Scotland
Marine Laboratory, Aberdeen

Research Fellow – Mathematician

■ **To study theory of population structure in marine ecosystems ■ Problems include, interaction of physical processes with community dynamics, factors determining population stability and effects of pollution on marine life ■ Computer simulation modelling involved.**

☐ 1st/2nd hons degree, or equivalent, in Mathematics ☐ Experience in numerical analysis and interest in ecological problems an advantage ☐ At least 3 years' postgraduate experience ☐ Appointment for 3 years as Senior Research Fellow (£2794-£3480 under review) ☐ Ref: SC/1/DLC.

Biologist

■ **Join team engaged on study of pollutants in marine ecosystems ■ Investigate effect of pollutants on food chains, leading to particular species of commercial fish ■ Design and operate field experiments to determine distribution of selected pollutants ■ Field and laboratory work involved.**

☐ Degree, or equivalent, in Biology – preferably good hons ☐ At least 2 years' postgraduate experience ☐ Interest in chemistry desirable ☐ Experience of experimental work, particularly with large-scale tank systems an advantage ☐ Age under 32 ☐ Appointment as Senior Scientific Officer (£2798-£3895) or Higher Scientific Officer (£2221-£2854) according to age, qualifications and experience ☐ Salaries under review ☐ Ref: SA/6/DLC.

☐ Application forms (for return by 12 June 1974) from Scottish Office, Personnel Management (PTS) 1, Room 214, 22/25 Queen Street, Edinburgh EH2 1LY, telephone 031-556 9222 ext. 762.

Science group
CIVIL SERVICE

(1900)

THE UNIVERSITY OF ASTON IN BIRMINGHAM
DEPARTMENT OF MATHEMATICS
LECTURERS

Vacancies exist for well qualified mathematicians/Statisticians in the Department of Mathematics. The Department is directly responsible for a first degree in Mathematics/Statistics, an M.Sc. course in Industrial Mathematics and Statistics and for research. In addition it offers a service to the University in the teaching of Mathematics and Statistics. The duties of those appointed will be in this service area. Preference will be given to those applicants whose research interests are in the application of mathematics/statistics to science and technology.

Commencing salary within the range £2,118 to £2,580 per annum on a scale rising to £4,896 per annum (payable with effect from October 1, 1974).

Requests for further details and application forms (which should be returned not later than June 3) should be sent, preferably on a postcard, quoting Ref. No. 974/6, to the Staff Officer, The University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET. (1912)

M.R.C. CLINICAL RESEARCH CENTRE
(Northwick Park Hospital)
Watford Road, Harrow, Middlesex HA1 3UJ
RESEARCH ON THE FUNCTIONAL PSYCHOSES

Applications are invited from suitably qualified candidates for a full-time research post in the recently established Division of Psychiatry at this Centre. The Division has been established to study physiological and biochemical correlates of mental illness and the successful candidate wil contribute to the psychological and behavioural aspect of these investigations.

The appointee will work on the psychological deficit in schizophrenia and some knowledge of biochemical or pharmacological aspects of psychiatric disease would be an advantage but is not essential.

Salary according to age and experience.

Further details and application forms may be obtained from Mrs. J. Tucker-Bull.

Please quote ref. 125/1. Closing date: Jun 29. (1914)

EAST BIRMINGHAM HOSPITAL
DEPARTMENT OF CLINICAL CHEMISTRY
BASIC GRADE BIOCHEMISTS

Due to expansion of the department and extended facilities vacancies have arisen for Basic Grade Biochemists. One post is available now, the other will be available in September. These posts are most suitable for those in, or about to qualify for, the post-probationary grade, for example with an M.Sc. in Clinical Chemistry, but other Honours Graduates would be considered.

The laboratories are well equipped and offer a wide range of activities giving full training for M.C.B. Automation is by single channel systems and reaction rate analysers, thus offering ample opportunities for development. Off line computer facilities are about to be installed. Several research programmes is collaboration with clinical staff are also being pursued.

Further details may be obtained from D. H. G. Sammons, Department of Clinical Chemistry, East Birmingham Hospital, Bordesley Green East, Birmingham B9 5ST, to whom all applications naming two referees should be made. (1915)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
DEPARTMENT OF BOTANY AND PLANT TECHNOLOGY
LECTURESHIP IN TIMBER TECHNOLOGY

A Lecturer is required from October 1, 1974, to undertake teaching and research in association with the Timber Technology section of the Botany Department, and to assist also in general departmental teaching preferably in the field of plant anatomy and morphology. The work of the section is concerned with the anatomy and fine structure, the processes of fungal decay, and the methods of preservation of timber. Postdoctoral or equivalent experience is desirable, and, given a knowledge of plant anatomy, could be in fungal physiology, enzymology, or plant biochemistry.

Initial salary in the range £2,118 to £3,636 plus £162 London Allowance, according to experience.

Further information can be obtained from Professor A. J. Rutter, Department of Botany, Imperial College of Science, Prince Consort Road, London, S.W.7, to whom applications, giving details of education and experience, and the names of two referees, should be made by June 14. (1919)

GUY'S HOSPITAL MEDICAL SCHOOL

JUNIOR TECHNICIAN OR TECHNICIAN

required for Gastroenterology Research Unit. For Junior Technician O.N.C. or Science A levels essential; for Technician H.N.C. Junior Technician salary scale rises to £1,395 plus £126 London Weighting; Technician scale £1,440 to £2,292 plus London Weighting.

Apply in writing to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. G.R. (1917)

The Open University

Research Assistant in Earth Sciences

Applications are invited for a Research Assistantship in Earth Sciences tenable from September 1, 1974, or as soon as possible thereafter. The person appointed will work with Professor I. G. Gass on Petrochemistry and genesis of volcanic rocks. Applicants should possess a good honours degree in Earth Sciences and post-graduate qualifications/experience in geochemistry. Commencing salary based on age, qualifications and experience, will be within the scale: £1,323 to £2,058 per annum (under review).

Details are obtainable from the Personnel Manager (RE1), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL. (Telephone Milton Keynes 74066, extension 3068).

Closing date: Monday June 3, 1974.

(1931)

MASSEY UNIVERSITY
Palmerston North, New Zealand

LECTURER/SENIOR LECTURER IN FOOD PROCESSING/PROCESS DEVELOPMENT

Applications are invited for the abovementioned position in the Department of Food Technology. Applicants should be suitably qualified in Food Technology, Chemical or Biochemical Engineering and have subsequently gained experience in food processing or applied food research. It is essential that the applicant have a strong quantitative approach to processing.

The major commitment of the appointee will be in teaching Food Processing and Process Development to undergraduate and postgraduate students taking the Food Technology option of the Technology Degree. He will be encouraged to develop liaison with one or more sectors of the food processing industry, and to develop an appropriate research area.

Appointment will be on the Lecturer-Senior Lecturer scale according to qualifications and experience.

Salary: Senior Lecturer NZ$8,718 to NZ$10,232 (bar) NZ$11,139; Lecturer NZ$6,753 to NZ$8,568. NZ$1=62p (approx.).

Further details of the position and of the University together with general conditions of appointment, may be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on **June 28, 1974.** (1953)

UNIVERSITY OF ABERDEEN
RESEARCH ASSISTANT IN BIOCHEMISTRY

Applications are invited for above post to work with Dr. S. B. Wilson, on aspects of ion uptake by potato mitochondria. The post is tenable for up to 3 years from October 1, 1974. Candidates should have an honours degree in biochemistry or a related subject or be graduating this summer. Suitably qualified candidates may be permitted to register for a higher degree. Salary within scale £1,305 by £87 to £1,479.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by June 22, 1974.

(1948)

Haematologist

This vacancy is within our new Toxicology and Drug Safety Unit and involves responsibility for the section studying the effects of drugs on the Blood Picture during the assessment of drug safety.

Applicants should possess a degree in Physiology or Biochemistry and have a sound knowledge of haematological techniques. An interest in, or experience of, Immunology would be advantageous but is not essential.

The Medicinal Research Centre is located close to Harlow New Town and combines easy access to London with proximity to pleasant countryside. Development Corporation housing may be available to suitable applicants at economic rent.

A competitive starting salary will be paid and there are the usual fringe benefits which one associates with a major British-based company.

If you would like to be considered for this post, please write, outlining your career to date, to:

BRL

John Atkinson,
Site Personnel Officer,
Beecham Research Laboratories,
The Pinnacles.
Harlow, Essex

1972

(1899)

The Hatfield Polytechnic
Principal Lecturer in Psychology
and
Senior Lecturer in Psychology

Immediate application is invited for these two appointments to begin in September, 1974.

Applicants must be specially well qualified either in experimental or physiological psychology. Both posts imply taking a significant role in teaching on an existing Honours BSc degree and on an MSc degree which is being planned. Staff are expected to develop their own research interests for which there are good facilities.

Salary scale: Principal Lecturer, £3,831 to £4,269 bar £4,815 per annum; Senior Lecturer, £3,522 to £3,912 bar £4,209 per annum.

Further details and application form may be obtained from The Staffing Officer. The Hatfield Polytechnic, PO Box 109, Hatfield, Herts AL10 9AB, or ring Hatfield 68100, Ext 309. Completed applications should be returned by 31 May, 1974.

Please quote reference 498. (1947)

UNIVERSITY OF EDINBURGH
FACULTY OF MEDICINE

Department of Biochemistry
University Demonstrator

The University Court invites applications for the post of Demonstrator which is tenable from 1st October, 1974. The appointment will be for one year in the first instance and subject to renewal annually up to a maximum of five years.

The major duties of the Demonstrator will be to participate in teaching programmes for medical, dental or science students. The initial salary will be at a suitable point on the scale £1659 - £2346 (under review).

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL, with whom applications (5 copies) together with the names of two referees should be lodged not later than 10th June, 1974. Please quote reference 1023.

(1941)

DUNSTAFFNAGE MARINE RESEARCH LABORATORY
Oban, Argyll

PHYSICAL OCEANGRAPHER

A Physical Oceanographer is required at the above laboratory to join a small group studying the circulation and mixing processes in the waters between the west coast of Scotland and Rockall Bank. The work will involve both hydrographic surveys from ships and measurements from moored buoys. Applicants should have at least a good honours degree; the appointment being at a level commensurate with age and experience. Application forms may be obtained from the Secretary, Scottish Marine Biological Association, P.O. Box 3, Oban, Argyll. (1951)

THE EDINBURGH SCHOOL OF AGRICULTURE
RESEARCH ASSISTANT

Applications are invited for a research assistantship tenable for 3-4 years to work on **Plasmodiophora brassicae** under the direction of Professor N. F. Robertson.

Applicants should possess a good honours degree and post-graduate experience in plant pathology.

Salary according to qualifications and experience: Grade III £2233 - £3895, or Grade IVa £1616 - £2060.

Further details and application form from the Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh, EH9 3JG. (1942)

UNIVERSITY OF LIVERPOOL

Department of Biochemistry

Applications are invited for the post of Research Assistant, financed by the Medical Research Council, to work on the role and regulation of bacterial ethanolamine kinase. The post is open to honours graduates in biochemistry. The appointment, which will be for three years, could be taken up as soon as possible. The post is available under the normal conditions for M.R.C. postgraduate awards. Applicants should indicate whether or not they would wish to work for a higher degree.

Applications, giving details of age, qualifications and experience and the names of two academic referees, should be received as soon as possible by the Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote ref RV/N/276022.

(1937)

NATIONAL INSTITUTE FOR MEDICAL RESEARCH
MILL HILL, LONDON

JUNIOR TECHNICIAN/TECHNICIAN required to assist in research on the metabolism of plasma proteins in the Division of Biophysics. Candidates should have a minimum of 4 GCE 'O' levels including biology and chemistry and preference will be given to those with GCE 'A' levels which should include chemistry. Experience of immunological methods would be an advantage. Those with GCE qualifications will be appointed as Junior Technicians on scale £834 (at 16) to £1,531 p.a. while HNC holders will be considered for appointment as Technicians £1,566 to £2,418 p.a. Please apply quoting ref: JT/BP.

JUNIOR TECHNICIANS/TECHNICIANS required to work in the Laboratory for Leprosy and Mycobacterial Research. Candidates with 'O' levels, 'A' levels or ONC will be considered for appointment as Junior Technicians £834 (at 16) to £1,461 p.a., while HNC holders will be appointed to the Technician grade £1,566 to £2,418 p.a. Two posts are available:

(a) To work using tissue culture techniques. Experience of sterile techniques would be a distinct advantage. (Quote ref: Lep/A).

(b) To work using bacteriological techniques particularly involving clinical trial material from overseas research units. Experience in bacteriology would be an advantage. (Quote ref: Lep/B).

ELECTRON MICROSCOPY TECHNICIAN familiar with thin tissue sectioning is required to assist in the examination of cells and sub-cellular components during animal development. Experience in electron microscopy would be an advantage. Initial salary, according to age, qualifications and experience, will be on scales £1,566 to £2,418 p.a. or £2,202 to £2,949 p.a. Please quote ref: EM/DB.

Applicants for these positions should write to J. H. Woodcock, N.I.M.R., The Ridgeway, Mill Hill, NW7 1AA. Tel: 01-959 3666 with details of age, qualifications and experience. (1952)

SCIENCE RESEARCH COUNCIL

DIRECTOR

ROYAL GREENWICH OBSERVATORY

Herstmonceux Castle, Hailsham, Sussex

The Science Research Council wish to appoint a successor to the present Director, Dr. A. Hunter, who is retiring on December 31, 1975.

The Observatory has a staff of about 220 and a budget of approximately one million pounds a year. Its programme of work is in three main areas: astronomical research; astronomical instrumentation; and the provision of national and international services for astronomy and navigation, including the National Time Service.

The Council intend that the Observatory shall become increasingly involved in the provision of national ground-based astronomy facilities for use by astronomers in universities and polytechnics as well as in the Royal Observatories. It will be a major task of the new Director to complete the restructuring of the Observatory that will be necessary to effect this change of work.

The post is pensionable either under the Council's own non-contributory Superannuation Scheme or under the F.S.S.U. Scheme. The Salary of £8,500 a year is under review.

Applications should be sent to Professor S. F. Edwards, F.R.S., Chairman, Science Research Council, State House, High Holborn, London WC1, to arrive before June 30, 1974.

Further information about the work and conditions of service may be obtained from the Chairman's Office. (1955)

University of London

CHAIR OF PHYSIOLOGY AT QUEEN ELIZABETH COLLEGE

The Senate invite applications for the above Chair which includes Headship of the Department of Physiology at the College. Initial salary to be agreed but not less than £5973 a year plus £162 London Allowance. Applications (10 copies) should be received not later than 20 June 1974 by the Academic Registrar, (N) University of London, Senate House, WC1E 7HU, from whom further particulars should first be obtained. (1945)

THE INSTITUTE OF PHYSICS

requires an

EDITORIAL ASSISTANT

to join its permanent staff in Bristol.

The Publishing Division of the Institute has a staff of about 60, many of whom are professionally qualified. The main activity is the publication of a range of international physics journals, and there are plans for expansion in this and related areas.

Applicants should be prepared to work steadily in a small editorial team. Working conditions are pleasant, in a modern office.

Candidates should have an honours degree or equivalent in physics, mathematics or chemistry. Starting salary (under review) between £1440 p.a. (minimum for a recent graduate) and £1800 p.a. with regular increases to £2340 p.a. and promotion prospects to £2940 p.a. No previous editorial experience is required. Training will be given in the basic techniques of sub-editing and proof reading, with the possibility of further training in wider aspects of publishing.

Further information and application form from: Managing Editor, Institute of Physics, Techno House, Redcliffe Way, Bristol BS1 6NX. (1936)

TEMPORARY RESEARCH OFFICER
(for nine months)

Psychophysiologist/Physiologist required as Temporary Research Officer on an EEG and Language Project in the Department of Linguistic and Regional Studies, University of Surrey. Candidates should be psychology or physiology graduates with research experience and should have knowledge of signal averaging and frequency analysis.

Salary: £166 per month.

Applications should be sent to: Professor H. P. Walz, Department of Linguistic & Regional Studies, University of Surrey, Guildford, Surrey GU2 5XH. (1925)

NATIONAL VEGETABLE RESEARCH STATION

SCIENTIFIC OFFICER required by Chemistry Section to take charge of a programme of fertiliser experiments on commercial vegetable farms. A degree, HND, HNC, or equiv. in horticulture or agriculture is required, and some training in field experimentation desirable. Driving licence essential. Starting salary in scale £1,435 - £2,329 p.a. according to qualifications and experience. Superannuation with allowance to offset contributions. Full particulars and application form (to be returned by 13th June 1974) from the Secretary, NVRS, Wellesbourne, Warwick CV35 9EF. (1928)

UNIVERSITY OF SYDNEY

The Henry Bertie and Florence Mabel Gritton Post-Graduate Research Scholarship

Applications are invited for the above-mentioned Scholarship from graduates of any university within the Commonwealth, or from graduates of any university who are British subjects. The Scholarship is tenable in the University of Sydney for up to three years.

The scholar will be expected to undertake post-graduate research in Chemistry as it is related to Industry or Agriculture.

Depending on the applicant's qualifications, the Scholarship will be awarded in either the senior grade (in the range of $A7,270 to $A8,413 per annum) or the junior grade (stipend $A3,550 per annum), plus other allowances, where appropriate, including a travel allowance.

Applications, which should include a certified copy of the applicant's academic record and the names of two referees, close with the Registrar, University of Sydney, N.S.W. 2006, Australia on **17 June 1974.**

Further information and application forms may be obtained from the Registrar's (1929)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
ROYAL SCHOOL OF MINES

LECTURESHIP IN MINERAL PROCESSING CHEMISTRY

Applications are invited for the post of Lecturer in Mineral Processing Chemistry in the Department of Mining and Mineral Technology. Applicants should have a good first degree, preferably in Chemistry (Physical), and several years of research or industrial experience in a field relevant to mineral processing, e.g. hydrometallurgy.

The successful candidate will be required to teach basic physical chemistry and its applications to mineral processing to undergraduate and postgraduate students, to take laboratory and tutorial classes, and to develop research work within the Department's area of activity.

The appointment will date from 1st October, 1974, or as soon as possible thereafter.

Initial salary, depending on age, qualifications and experience, will be within the Lecturer scale £2,118-£4,896 plus £162 p.a. London Allowance. F.S.S.U. superannuation benefits apply.

Further information and an application form can be obtained from Professor M. G. Fleming, Department of Mining and Mineral Technology, Royal School of Mines, Imperial College of Science and Technology, London SW7 2BP.

(1922)

The University College of Wales
Aberystwyth

DEPARTMENT OF BIOCHEMISTRY

Applications invited for a postdoctoral appointment as RESEARCH ASSOCIATE to work with a group studying the microbial metabolism of alicyclic compounds.

Experience of microbial biochemistry, the metabolism of cyclic structures or of mixed function oxygenase systems and enzyme purification an advantage.

Two years from 1 October. Initial salary: £2,058 per annum.

Enquiries to Dr. P. W. Trudgill, Department of Biochemistry, U.C.W. Aberystwyth. (Tel. 0970 3111 Ext. 100). Application forms available from the Registrar. (1926)

THE QUEEN'S UNIVERSITY OF BELFAST

Department of Pure and Applied Physics

Research Associate

Applications are invited for the post of Research Associate tenable from 1st October 1974. The successful applicant will be expected to carry out research within large well equipped research groups in one of the following fields:

(a) Atomic and molecular collision physics.

(b) Laser physics, non-linear optics and opto-electronics.

(c) Thin film optics.

Candidates should possess a Ph.D. degree and relevant research experience. Salary wil be dependent on qualifications and experience within the range £2,118 to £2,412, normally plus F.S.S.U.

The appointment will initially be for one year but is renewable annually thereafter. Applications giving full details of academic record and experience together with the names of two referees should be sent to the Personnel Department, The Queen's University of Belfast BT7 1NN, Northern Ireland, before May 29th.

(1923)

FELLOWSHIPS AND STUDENTSHIPS

MINISTRY OF AGRICULTURE, FISHERIES AND FOOD

Research Fellowship Myopathy in Farm Animals

Applications are invited for a Research Fellow to work on morphological aspects of muscle disorders in farm animals. The Fellow will be attached to the Department of Pathology of the Central Veterinary Laboratory, Weybridge, and will join a multidisciplinary group concerned mainly with developmental myopathies in pigs, cattle and sheep.

QUALIFICATIONS. Candidates should have a basic degree in veterinary science or in biology with PhD (or equivalent) and considerable post graduate experience in either muscle biology or pathology.

Appointment would be at the level of Junior or Senior Research Fellow, though appointment at Principal Research Fellow level might be considered in the case of an exceptionally well qualified candidate.

REMUNERATION. The value of the Fellowship will be determined by the interview but will lie within the following ranges:-

Principal Research Fellowship	£3,713 - 4,898
Senior Research Fellowship	£2,794 - 3,480
Junior Research Fellowship	£1,914 - 2,498

Application forms may be obtained from Mr. J. S. Barnes, Ministry of Agriculture, Fisheries and Food, Room 6/11, Victory House, 30-34 Kingsway, London WC2B 6TU. Telephone 01-405 4310, Ext 308.

Closing date for completed forms 14th June 1974.

(1858)

Post Doctoral Research Fellow

required in Department of Applied Biology and Food Science. (Head: Dr. P. Wix).
to work in one of the following fields:—

Invertebrate toxicology or physiology
Helminthology
Fresh water microbiology or ecology
Physiology of fresh water plants
Microbial biochemistry
Fermentation technology
Food volatiles
Food additives
Food product development

The successful applicant will be expected to initiate and develop research and may be required to arrange an annual programme of Seminars.

Salary: £2,151—£2,421

Apply by letter, stating full personal and career details, to the Clerk to the Council (Room 665), Polytechnic of the South Bank, Borough Road, London SE1 0AA.

Polytechnic of the South Bank

(1956)

AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF EARTH SCIENCES

PROFESSOR/PROFESSORIAL FELLOWSHIP (2 Posts)

The Research School of Earth Sciences, under the direction of Professor A. L. Hales, proposes to develop research in three areas, Economic Geology, Environmental Geochemistry and Geophysical Fluid Dynamics. It is proposed to make senior appointments in two of these three fields initially.

Economic Geology: The successful appointee will be expected to lead a group or Department conducting basic research directed towards the scientific study of mineral deposits, including their petrology, geochemistry, geological environment and genesis. Fundamental investigations of the chemistry of ore-forming solutions and the entire range of physico-chemical processes occurring between the ultimate source and depositional locale are also envisaged. Experimental and laboratory investigations devoted to these topics will constitute an important aspect of the activities of the Department or group and applicants should have appropriate backgrounds in these areas.

Environmental Geochemistry: The successful applicant will be expected to lead the researchers of a group or of a department working in broadly-based and fundamental aspects of the field of environmental geochemistry. It is intended that researches in this area will be directed towards the large-scale chemical interactions between the atmosphere, oceans, solid earth and biosphere. The geochemical cycling of elements between these reservoirs (including specialised interface studies) and the chemistry of these reservoirs (particularly the atmosphere and oceans) will also be investigated. The use of physicochemical tracer techniques to study the dynamical circulations of the oceans and atmosphere is also envisaged. Another field of concern to the research group or department will be palaeoclimatology. The approach to be adopted towards these problems will have a strong experimental bias with intensive application of sophisticated isotopic, radiometric and trace element analytical techniques.

Geophysical Fluid Dynamics: The successful appointee will be expected to lead a group or Department conducting basic research in fluid dynamics as applied to geophysical processes. Studies of the large scale motions of the sea and/or atmosphere will be emphasised in the initial stages of the development. Although the group may not be involved initially in data collection it is envisaged that the analysis of data, both physical and chemical, relevant to the problems of the large scale motions of the sea and atmosphere and their interactions will form an important part of its activities.

Salaries: Salary for a Professor is $A19,102 per annum and for a Professorial Fellow $A17,648 per annum.
Other Conditions: Tenure—To retiring age (at present 65).

Reasonable travel expenses are paid and assistance with housing is provided. Superannuation is on the F.S.S.U. pattern with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Candidates are urged to write to Professor A. L. Hales, Director, Research School of Earth Sciences, Australian National University, P.O. Box 4, Canberra, ACT 2600, Australia, for further information.

G. E. Dicker, Acting Academic Registrar. (1933)

UNIVERSITY OF ABERDEEN
UNIT FOR RESEARCH ON ADDICTIVE DRUGS

A S.R.C. Studentship (Co-operative Award in Science and Engineering, C.A.S.E.), will become available on October 1, 1974. It is tenable for 3 years in co-operation with the Pharmaceutical Division of Reckitt and Colman Ltd., Hull, and is open to First and Upper Second Class Honours Graduates in Pharmacology, Biochemistry or Physiology. The research project is concerned with the action of newly-synthesized morphine-like compounds on neurotransmitter release and on behavioural patterns in normal and morphine-dependent animals.

Applications (3 copies) to be submitted to Professor H. Kosterlitz, from whom further particulars may be obtained, University of Aberdeen, Marischal College, Aberdeen AB9 1AS, not later than May 31, 1974. (1844)

UNIVERSITY OF WARWICK
Postdoctoral Fellowship in Biological Sciences

Applications are invited for the above post to work on the biochemistry of virus RNA replication. The post would be suitable for a biochemist with an interest in animal virology or a virologist with a good knowledge of biochemistry. Experience of working with nucleic acids or their polymerases would be an advantage. The appointment is for twelve months commencing October 1, 1974. Salary in the range £2,118 to £2,247 to £2,412 p.a. with F.S.S.U. Further details and application forms may be obtained from the Academic Registrar, University of Warwick, Coventry CV4 7AL, to whom completed forms should be returned by May 27, 1974, quoting Ref. No. 40/Q/74. (1852)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENTS OF BIOLOGY AND CHEMISTRY

Applications are invited for an S.R.C. Studentship, starting in October 1974, for work on predator-prey interactions of tropical ants and termites. In particular, defensive secretions will be studied with a view to the development of integrated control methods. This will involve collaboration with the Centre for Overseas Pest Research and fieldwork in Nigeria.

Further particulars may be obtained from the Academic Registrar's Department, The University, Southampton SO9 5NH, to whom applications should also be sent. (1812)

CHELSEA COLLEGE
University of London

Applications are invited for the post of POST-DOCTORAL RESEARCH FELLOW as member of an S.R.C. supported team investigating THE INTERACTION OF THE HUMAN THERMO-REGULATORY AND CARDIOVASCULAR CONTROL SYSTEMS in collaboration with the Engineering in Medicine Laboratory at Imperial College.

The successful candidate will probably be a Physiologist with an interest in human experimentation and data analysis, but applications from candidates with other backgrounds but a real interest in the project will be welcomed.

The appointment will be for three years commencing as soon as possible. Salary: £1,746 to £1,920 to £2,091 per annum. Superannuable. Application forms from the Personnel Office, Chelsea College, Manresa Road, London SW3 6LX. (1845)

RESEARCH STUDENTSHIP

Applications are invited for a research studentship to study the photodegradation and photostabilisation of acrylonitrile-butadienestyrene copolymers. This will involve the study of a novel photo-stabilisation mechanism and will be carried out in collaboration with an industrial research laboratory. Candidates with an interest in organic and/or polymer chemistry will be preferred. The studentship will be at current S.R.C. rates and will be renewable annually up to a maximum of three years.

Applications to:

Professor G. Scott,
Department of Chemistry,
University of Aston in Birmingham,
Gosta Green,
Birmingham B4 7ET. (1821)

UNIVERSITY OF DURHAM
DEPARTMENT OF BIOLOGY

Applications are invited for studentships tenable from October 1, 1974, from chemists, biochemists or botanists, to work on the biochemistry of grain legume improvement. Successful candidates may register for a higher degree.

Applications to Professor D. Boulter, Department of Botany, Science Laboratories, South Road, Durham DH1 3LE. (1813)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
DEPARTMENT OF PHYSIOLOGY
Cardiovascular Research

Applications are invited from honours graduates or prospective honours graduates in physiology, pharmacology or a related discipline, for a studentship for training in research methods tenable from October 1974. The holder will be eligible for registration as Ph.D. student of the University. The value of the award and conditions of appointment will be those of M.R.C. Studentships.

Facilities are available for the postgraduate student to join a group working on several aspects of autonomic nervous control of the cardiovascular system in animals and in man, under the supervision of Dr. P. H. Fentem. Applicants should write to Dr. Fentem giving a brief curriculum vitae and the names and addresses of two referees, at the Department of Physiology, The Medical School, University of Nottingham, Nottingham NG7 2RD. (1820)

Dunstaffnage Marine Research Laboratory

Applications are invited for a research studentship funded by the Natural Environment Research Council to work on the breakdown of organic material in near shore marine sediments. The studentship would be tenable for a period of three years and the applicant would be required to register for a Ph.D. under the regulations of the University of Dundee. The student would be part of a small multidisciplinary team working on the long term effects of particulate effluents on sea lochs in the West of Scotland. Application forms and further information can be obtained from the Director, Dunstaffnage Marine Research Laboratory, P.O. Box 3, Oban, Argyll PA34 4AD. (1863)

POSTGRADUATE STUDENTSHIP

Applications are invited from graduates with first or upper second class honours degree. A general knowledge of biochemistry is required, preferably with specialisation in mitochondrial or muscle biochemistry.

The successful candidate will be expected to study the general biochemical properties of red and white, and fast and slow muscles. The project would involve assay of the myoglobin haemoglobin and mitochondrial contents of the muscle, together with a study of their myofibrillar ATP-ase, mitochondrial and Ca-pump activities.

The work is expected to form the basis of an M.Sc. or Ph.D. thesis.

Further particulars of award, allowance, together with a form of application from:

Secretary, Meat Research Institute, Langford, Bristol BS18 7DY. (1831)

UNIVERSITY OF LEICESTER

Applications are invited for a C.A.S.E. Studentship. The successful applicant will work with Professor M. C. R. Symons on a research project entitled "Quantitative Study of Autoxidation Reactions with the aid of E.S.R. and Kinetic Techniques". The research will be conducted in co-operation with Dr. N. Uri and the student will spend a proportion of his/her time at the Research Laboratories at Waltham Abbey during the 3-year Ph.D. training.

Applications should be made to Professor M. C. R Symons, Department of Chemistry, University of Leicester LE1 7RH, from whom further details may be obtained. (1815)

THE UNIVERSITY OF MANCHESTER
DEPARTMENT OF LIBERAL STUDIES IN SCIENCE

Applications invited for Research Studentships supported by the S.R.C. tenable from October 1. The Department is engaged in teaching and research on economic, social, political and historical aspects of science and technology. Research topics can be chosen from the role of science and technology in public policy, sociology of science and technology, economics and innovation, technology assessment, or related areas. Applicants should have, or expect shortly to obtain, a first or upper second class honours degree, preferably incorporating elements from both the natural and social sciences. Applicants with specialist science or social science degrees may be accepted subject to the completion of appropriate coursework. Applications, giving full details of qualifications and experience and names of two referees, and indicating a preference regarding research area, should be sent to Dr. R. D. Johnston, Department of Liberal Studies in Science, The University, Manchester M13 9PL by June 7. (1819)

QUEEN MARY COLLEGE
University of London
KINETIC SPECTROSCOPY

Two S.R.C. supported Postdoctoral Fellowships are available from September/October 1974 for 1 or 2 years, for work with Dr. M. A. A. Clyne. One is for a new project on laser-induced fluorescence of diatomic and triatomic free radicals in the gas phase. A background in spectroscopy of small molecules, vacuum techniques, gas kinetics or lasers an advantage.

The other post is for studies of elementary reactions of ground state atoms, including halogen atoms, using vacuum ultraviolet atomic resonance spectrometry linked to a discharge-flow system. A background in spectroscopy of atoms or small molecules, gas kinetics, vacuum techniques or fluorine inorganic chemistry of small molecules an advantage.

Salary (under review) in range £1,929 to £2,223 p.a. plus £162 London Allowance. Applications (giving age, qualifications, experience and names and addresses of two referees) as soon as possible to The Registrar, Queen Mary College, Mile End Road, London E1 4NS. (1824)

UNIVERSITY OF SOUTHAMPTON
RESEARCH FELLOW IN GAMMA RAY ASTRONOMY

Application is invited for the post of Research Fellow to work on the development of a telescope for Low Energy Gamma Ray Astronomy using high altitude balloons. Applicants should be familiar with particle counting techniques and associated electronic circuitry. The post is initially for two years. Candidates should possess a Ph.D. degree or equivalent qualification. Salary will be in the range £1,929 to £2,388 plus F.S.S.U. Applications including curriculum vitae and the names and addresses of two referees should be sent to the Deputy Secretary's Section, The University, Southampton SO9 5NH, quoting reference number 223/R/Na. (1834)

University of Strathclyde
Department of Metallurgy

RESEARCH FELLOWSHIP: ELECTRONIC STRUCTURE OF ALLOYS

Applications are invited for a Research Fellowship, tenable in the first instance for 1 year and renewable for a further year, from candidates with interests in MATERIALS PHYSICS. The salary will be within the range £1929 — £2553, with placing according to qualifications and experience. F.S.S.U. benefits.

The successful applicant will work with an established group, supported by the Science Research Council, in the field of ELECTRONIC STRUCTURE OF METALS AND ALLOYS studied by soft X-RAY SPECTROSCOPY and X-RAY PHOTOELECTRON SPECTROSCOPY. A PhD. in physics, metallurgy or chemistry, and relevant research experience is desirable.

Applications (quoting R 14/74) should be addressed to Dr. L. M. Watson, Department of Metallurgy, Colville Building, 48 Portland Street, Glasgow, G1 1XM. (1902)

HERIOT-WATT UNIVERSITY - EDINBURGH
Postgraduate Research Studentships in Department of Physics

Prof. S. D. Smith **Tel. 031-449 5111**

Applications are invited for SRC, NERC and University Research Studentships tenable for 3 years from September 1974. The principal research interests of the Department are in solid state and laser physics, non-linear optics, tunable laser spectroscopy and satellite meteorology. Active and substantial projects are current on applications of the spin-flip Raman laser, opto-acoustic spectroscopy with tunable dye lasers and the remote measurement of atmospheric temperature and pressure from satellites. (1851)

MEDICAL RESEARCH COUNCIL OF NEW ZEALAND
University of Otago Dental School
SENIOR RESEARCH FELLOWSHIP

Applications are invited from suitably qualified graduates for the above-mentioned position. Proven experience in research and the ability to initiate and direct projects is essential, although applicants need not necessarily be dentally qualified. The principal task of the appointee will be to carry out research in connective tissue biology. It is hoped that the appointee will also be prepared to act in a consultant capacity to other research workers.

There are, at the appointee's disposal, facilities for histology, histochemistry and some biochemical analytical procedures. The acquisition of a new transmission electron microscope is currently being negotiated. It is expected that the appointee will apply eventually to the Council for other equipment and technical assistance necessary for his own research. Travel grants will also be made to allow attendance at approved scientific conferences.

The initial salary will depend on the qualifications and experience of the appointee but will be comparable with what he would be offered in the university at the level of senior lecturer but in the case of an exceptionally well qualified applicant the Council will consider appointment at a level equivalent to that of Associate Professor. The Council will also pay the employer's contribution to superannuation and in the case of an appointment from overseas, financial assistance will be given for travel at rates and under conditions determined by the Council.

Further information and form of application may be obtained from J. A. Borrows, Technical Secretary, at P.O. Box 6063. Dunedin. New Zealand, with whom applications close on **July 31, 1974.** (1826)

RESEARCH STUDENTSHIPS IN PHARMACOLOGY

Applications are invited from graduates in pharmacology, biochemistry or physiology for Research Scholarships, to work on projects in neuropharmacology and immunopharmacology. Successful applicants will be expected to register for a higher degree.

Applicants should send their c.v. and names and addresses of two referees to Professor J. L. Mongar, Department of Pharmacology, UNIVERSITY COLLEGE LONDON, Gower Street, London WC1E 6BT. (1913)

IMPERIAL COLLEGE LONDON
DEPARTMENT OF ZOOLOGY AND APPLIED ENTOMOLOGY
RESEARCH STUDENTSHIP IN PARASITOLOGY

Applications are invited for an S.R.C. Research Studentship (under the co-operative award science and engineering scheme) to study the biology of the sheep tapeworm MONIEZIA EXPANSA.

The project will involve a close collaboration between the Department of Zoology and the Pharmaceutical Division of Imperial Chemical Industries. The award holder will be expected to carry out part of the work each year at the I.C.I. Laboratories.

Candidates should have a 1st or upper 2nd class Honours Degree or an M.Sc. in a biological science.

The studentship will be at the current S.R.C. rate (£695 p.a.).

Applications, giving the names of 2 referees, should be sent to Professor J. D. Smyth, Department of Zoology, Imperial College, London SW7 2BE (Phone 01-589 5111, Ext. 2264).

Closing date: May 25, 1974. (1838)

UNIVERSITY OF EXETER
DEPARTMENT OF PHYSICS
RESEARCH STUDENTSHIP

The Science Reesarch Council has allocated a C.A.S.E. (Cooperative Award in Science and Engineering) studentship for three years (starting October 1974) to suitably qualified graduates interested in carrying out at the University of Exeter a "Study of frequency and time dispersion of high frequency radio waves".

The cooperating body is the Royal Aircraft Establishment, Farnborough. The value of the award is not less than £695 or £540 (for students living in the parental home).

Applicants should possess, or expect to obtain in the Summer of 1974, a first or upper second class honours degree.

Further details and application forms can be obtained from:

Professor G. K. T. Conn,
Department of Physics,
University of Exeter,
Stocker Road,
Exeter EX4 4QL.

Applications should be sent in as soon as possible and in any case not later than June 15, 1974. (1903)

UNIVERSITY OF RHODESIA
FACULTY OF SCIENCE
SENIOR LECTURESHIP OR LECTURESHIP IN MATHEMATICS

Applications are invited for a Senior Lectureship or Lectureship in the Department of Mathematics.

Salary Scales and Conditions (approximate conversions from Rhodesian $): Senior Lecturer £5,346 by £214 to £7,058; Lecturer Grade I £4,857 by £180 to £5,577; Lecturer Grade II £2,994 by £154 to £3,456 by £171 to £3,798 by £180 to £4,518 by £170 to £4,688.

Family passages and allowance for transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Rhodesia. Sabbatical and triennial visits with travel alllowance. Superannuation and medical aid schemes.

Applications: (6 copies) giving full personal particulars (including full names, place and date of birth, etc.), qualifications, experience and publications and naming three referees, should be submitted by **June 15, 1974** to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP 167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained. An additional copy should be sent to the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF, from whom further particulars may also be obtained. (1954)

ROYAL HOLLOWAY COLLEGE
(University of London)
Egham Hill, Egham, Surrey
A TUTORIAL RESEARCH STUDENTSHIP

is offered in DEPARTMENT OF ZOOLOGY (Comparative Physiology) from October 1, 1974 at an award of £800 a year. Further details may be obtained from the Personnel Officer to whom applications should be sent as soon as possible. (1904)

UNIVERSITY OF SUSSEX
RESEARCH FELLOWSHIP IN BIOCHEMISTRY

Applications are invited for a post-doctoral fellowship in the Biochemistry group, tenable for 2 years from August 1, 1974. The successful candidate will join a group studying the control of protein synthesis in mammalian cells, and prior experience in a related area would be an advantage.

Salary will be on the Research Fellow scale, with initial placement in the range £2,118 to £2,931.

Applications including a curriculum vitae and the names of two referees should be sent to Dr. J. E. Kay, School of Biological Sciences, University of Sussex, Brighton BN1 9QG. (1901)

LASER-INDUCED TRANSITIONS

Applications are invited for a Postdoctoral Research Fellowship tenable in the Davy Faraday Research Laboratory of the Royal Institution (Director: Professor Sir George Porter, F.R.S.). The successful candidate will investigate transient chemical and physical phenomena occurring in the nanosecond and picosecond time regions. Applicants should be experienced in the use of pulsed lasers and general electro-optic techniques. The appointment is tenable for one year, and subject to satisfactory performance, renewable up to three years. The salary scale is £2,400 to £3,000 p.a.

A curriculum vitae and the names of two referees should be sent to Dr. M. A. West, The Royal Institution, 21 Albemarle Street, London W1X 4BS, U.K., by **June 28, 1974.** (1898)

UNIVERSITY OF READING
DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY

The Ministry of Agriculture, Fisheries and Food is prepared this year to offer to a suitable candidate a Studentship tenable in the Department of Physiology and Biochemistry in the University of Reading. The value of the MAFF award in 1974 will normally be £695 per annum. This studentship is for a place on the taught course for an M.Sc. in Physiology and Biochemistry of Farm Animals to start in October 1974 and lasting nine months. Applicant should hold at least a Lower Second Class degree in a suitable subject or hope to qualify this summer. Further particulars may be obtained from: Professor C. Tyler, Department of Physiology and Biochemistry, The University, Whiteknights, Reading RG6 2AJ. Ref. M.N.16. (1892)

UNIVERSITY OF DUNDEE
DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS
RESEARCH STUDENTSHIP

Applications are invited for an M.R.C. Research Studentship for training in research methods available from October 1, 1974, for up to three years. The training programme available is entitled "Methods of Studying Plasma and Tissue Binding of Drugs" and the work will be carried out in the Department of Pharmacology and Therapeutics in the new Ninewells Hospital and Medical School complex.

The successful applicant may register for a Ph.D. degree and will receive a stipend in accordance with the rates for M.R.C. scholars.

Candidates should have, or expect to obtain this year, a first or upper second class honours degree or equivalent in pharmacy, pharmacology, biochemistry or related subject. Applicants should write to Professor J. Crooks, Department of Pharmacology and Therapeutics, University of Dundee DD1 4HN, giving their qualifications and the names of two referees. Applications should be submitted by May 31. (1866)

UNIVERSITY OF NEW SOUTH WALES
SCHOOL OF BOTANY
Teaching Fellow

Good honours degree in botany or agriculture required. Initial appointment is for one year with prospects of annual renewal for a further two years; appointee will undertake research for a higher degree and will have some teaching duties.

Salary: between $A5,740 and $A7,015 per annum. Commencing salary according to qualifications and experience

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on **7 June 1974.** (1943)

PORTSMOUTH POLYTECHNIC
Department of Biological Sciences
S.R.C. Case Research Studentship

The S.R.C. has awarded a CASE research studentship for a neurophysiological and toxicological study of the mode of action of pyrethroid insecticides in locusts. The work will be done in collaboration with Rothamsted Experimental Station, and the student will be expected to spend a significant period of time in the Insecticides and Fungicides Department at Rothamsted.

Applicants should have, or expect to obtain, a First or Upper Second class degree in a biological science, or its equivalent. The student will be expected to register for a Ph.D.

Application forms and further particulars may be obtained from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth, PO1 2QQ, to whom completed applications should be returned by 3rd June 1974. Please quote ref. B.10. (1946)

THE QUEEN'S UNIVERSITY OF BELFAST
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post, which involves the investigation of biochemical aspects of animal viruses. Applicants should have experience in some aspects of protein chemistry, enzymology, immunology or virology. The position will be financed by the Agricultural Research Council at a salary from £1,929 by £131 per annum plus F.S.U. according to age and qualifications.

Applications, including the names of two persons to whom reference may be made, should be sent to Dr. S. J. Martin, Department of Biochemistry, Medical Biology Centre, Queen's University of Belfast, 97 Lisburn Road, Belfast BT9 7BL, Northern Ireland. (1875)

UNIVERSITY OF WARWICK
RESEARCH FELLOWSHIP IN THEORETICAL PHYSICS

Applications are invited for a Postdoctoral Research Fellowship in the Department of Physics. The field of study will be low mobility, narrow band materials containing transition metals. Of particular interest are metal-insulator and metal superconductor phase transitions associated with lattice instabilities in such materials. The fellowship is tenable for a period of up to two years in the salary range £2,118, £2,247, £2,412 p.a. (exceptionally £2,580 p.a.), with FSSU. Letters of application (no forms) giving details of previous experience should be sent to the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No: 41/2Q/74. Closing date for receipt of applications is 31st May, 1974. (1938)

THE UNIVERSITY OF SHEFFIELD
RESEARCH STUDENTSHIPS IN SOLID STATE PHYSICS

Applications are invited for two C.A.S.E. Research Studentships, tenable from October 1, 1974, leading to the degree of Ph.D., on the following: (1) Radiation damage effects on the electrical and optical properties of transparent semi-conductors, in collaboration with the British Aircraft Corporation. (2) High field and photo-effects in semiconducting glasses, in collaboration with S.T.L., Harlow. The awards will be at the appropriate rate for S.R.C. studentships. Candidates should have or expect to gain a first or upper second class honours degree in physics or a related subject. Applications giving full curriculum vitae and names of two referees should be sent as soon as possible to either Dr. I. G. Austin or Dr. T. M. Searle, Department of Physics, The University, Sheffield S3 7RH. (1950)

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF CHEMISTRY

Applications are invited for the following:

1. POSTDOCTORAL RESEARCH FELLOWSHIP for studies on chemical carcinogenesis. The appointee will join a team working on chemical and biochemical aspects of polycyclic aromatic hydrocarbon binding to DNA, ranging from synthetic and structural organic chemistry to tissue culture. Candidates should hold (or expect to gain) a Ph.D. in organic or biological chemistry and experience in nucleic acid chemistry is desirable but not essential. The appointment is from October 1, 1974 or a date to be arranged until September 30, 1975 at a salary not less than £1,923 per annum plus F.S.S.U.

2. AN S.R.C. (C.A.S.E.) STUDENTSHIP for a project involving the synthesis of a novel group of heterocyclic compounds. These are designed to possess controlled chemical reactivity and potential herbicidal character. The work will be carried out in conjunction with I.C.I. Plant Protection Limited and part of the programme will be performed at their Jealott's Hill Research Station. Applicants should have (or expect to obtain this summer) a good Honours degree or G.R.I.C. in chemistry and the successful candidate will be expected to register for a Ph.D.

Applications for either of the above, including a curriculum vitae and names and addresses of two referees to: Dr. G. M. Blackburn, Department of Chemistry, The University, Sheffield S3 7HF (from whom further information is available in respect of the Studentship). (1949)

LECTURES AND COURSES

UNIVERSITY OF OTAGO
Dunedin, New Zealand
LECTURER OR SENIOR LECTURER IN MINERAL TECHNOLOGY

Applications are invited for a position within the grade of Lecturer/Senior Lecturer in the Department of Mineral Technology. Applicants should have recognised qualifications in the field of mineral processing and experience in the application of mathematical methods to problems in the mineral industry. A knowledge of physical and applied chemistry would be an advantage.

Salary Scales: Lecturer: $NZ6,753 to $NZ8,568 per annum; Senior Lecturer: $NZ8,718 to $NZ11,139 per annum with a bar at $NZ10,232 per annum.

Academic salary scales are subject to both triennial review and regular cost-of-living adjustments.

Further particulars are available from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF or from the Registrar of the University.

Applications close in New Zealand and London on **August 15, 1974.** (1829)

FEBS Advanced Course No. 32

Ion Transport and Mitochondrial Function

Budapest 31 August—1 Sept. 1974

This Advanced Course will take the form of a colloquium in which a panel of experts will lead discussions on (1) Transport of Substrate Anions: Mechanisms and Physiological Implications; (2) Relationship between Proton Transport and Mitochondrial Function; and (3) Transport of Cations: Mechanisms and Physiological Implications.

Participants may be able to present 10-minute communications on relevant results.

Fee: Swiss Fr. 30.00.

Enquiries as soon as possible to Dr. A. Fonyo, H-1082 Budapest, Ülloi ut 78/a, Hungary. (1842)

University of Bradford

POSTGRADUATE SCHOOL OF STUDIES IN PHARMACOLOGY

MSc COURSE IN EXPERIMENTAL PHARMACOLOGY

Applications are invited from graduates in pharmacology, pharmacy or other appropriate subjects, for admission to the course starting in October, 1974. The course is of one year in duration and consists of four parts concerned with quantitative pharmacology, toxicology, psychopharmacology and a research project. The aim is to provide instruction and experience of research methodology as appropriate to the investigation of mechanisms of action of drugs.

Further information and application forms are obtainable from the Secretary of the School of Studies in Pharmacology, University of Bradford, Yorkshire BD7 1DP. (1865)

JAMES COOK UNIVERSITY OF NORTH QUEENSLAND

Applications are invited for the following appointments:

LECTURER IN GEOGRAPHY: Applicants should have a good honours degree in Geography or related field and, preferably, should also have a higher degree or be well on the way to the completion of the relevant research. An ability to teach and research in the physical or human aspects of resource management and evaluation is required.

LECTURER IN ZOOLOGY: Applicants should have an initial degree in Zoology or Biology, a Ph.D. and some experience in university teaching and research. The successful applicant will be required to continue teaching the existing courses in Entomology and to contribute to the general teaching programme in Zoology.

Salary range: $A8,698 - $A11,982 per annum, plus locality allowance of $A142 p.a. for a married male or $A71 p.a. for a single appointee. Conditions of appointment include F.S.S.U. superannuation, invalid pension scheme, housing assistance, study leave and allowance for travel and removal expenses on appointment.

Closing dates: Lectureship in Geography **14 June;** other post **7 June 1974.**

Further details and application forms obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (1932)

UNIVERSITY OF SURREY LECTURER IN HUMAN BIOLOGY
DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for the post of Lecturer in Human Biology, tenable from September 1, 1974. The salary will be on the Lecturer scale £2,118 to £4,896 (1.10.74), and the post is superannuable under F.S.S.U.

Further particulars may be obtained from the Academic Registrar (LFG), University of Surrey, Guildford GU2 5XH. Telephone: Guildford 71281, extension 452. Applications, in the form of a curriculum vitae, including the names and addresses of two referees and present salary, should be sent to the same address by Friday, June 14, 1974. (1833)

UNIVERSITY OF DURHAM
DEPARTMENT OF PSYCHOLOGY

Applications are invited for the post of LECTURER IN PSYCHOLOGY from October 1, 1974, or such later date as may be arranged.

Salary on the scale £1,929 to £4,548 per annum (under review), plus F.S.S.U. benefits.

Applications (three copies) naming three referees should be sent by May 31, 1974 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (1856)

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF GEOGRAPHY

Applications are invited for the following posts in the above Department, both tenable from October 1, 1974:

1. LECTURER, in the field of PHYSICAL GEOGRAPHY; preference will be given to persons with an interest and research experience in soils and/or hydrology. Initial salary in the range £1,929 to £2,388 on the scale £1,929 to £4,548, with F.S.S.U. provision.
2. JUNIOR RESEARCH FELLOW; candidates should be geographers. Salary £1,473 a year.

Further particulars from the Registrar and Secretary, The University, Sheffield S10 2TN, to whom applications (5 copies) should be sent by May 25, 1974 Quote Ref. R.69/G. (1849)

LA TROBE UNIVERSITY
VICTORIA, AUSTRALIA

LECTURER/SENIOR LECTURER IN PURE MATHEMATICS

Applicants are invited for the above-mentioned position. The successful applicant will be expected to carry out normal teaching duties while continuing with mathematical research.

Salary: Senior Lecturer $A12,268 to 5 by $A408 to $A14,308; Lecturer $A8,698 to 1 by $A470 to 6 by $A469 to $11,982.

Further information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, La Trobe University, Bundoora, Victoria, Australia 3083.

Aplications close on **June 30, 1974.** (1827)

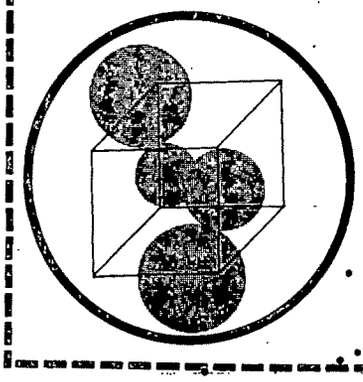
Biological differentiation -a new journal.

Biological research has for too long suffered from restricted experimental attitudes and 'vertical' thinking.

Now Differentiation, an important new publication, provides the opportunity for interdisciplinary communication and increasing fertilization of ideas across the artificial boundaries created by overspecialization. This journal, published bi-monthly, offers up to date information and synthetic views of a problem underlining the whole biological phenomenon – differentiation.

The first five issues contained papers on:
Degree of differentiation in nonproliferating cells of mammary carcinoma. C. V. Wylie, P. K. Nakane and G. B. Pierce.
Polyribosome profiles and polyribosome-associated RNA of Friend leukaemia cells following DMSO-induced differentiation. H. D. Preisler, W. Scher and Charlotte Friend.
Studies on cytology and differentiation in Sciaridae. 5. Electron microscopic studies on the salivary glands of *Bradysia elegans* Morgante (Diptera, Sciaridae). A. B. Da Cunha, R. W. Reiss, C. Pavan, J. J. Biesele, J. S. Morgante and M. C. Garrido.
The principle of sequential dependence in cellular differentiation. P. A. Riley.
Time lapse filming of cellular interactions in organ culture. 2. The behaviour of malignant cells. E. J. Ambrose and Dorothy M. Easty.
Intercellular levels of cyclic nucleotides during cell enlargement and cell division in excised tobacco pith tissues. C. V. Lundeen, H. N. Wood and A. C. Braun.
Pattern formation in *Dictyostelium discoideum*: temporal and spatial distribution of prespore vacuoles. Ursula Muller and R. Hohl.
The enrichment of egg-type RNA in cleavage stage embryos of the sand dollar *Dendraster excentricus*. Shigeki Mizuno, H. R. Whiteley and A. H. Whiteley.
DNA synthesis and the production of antibodies by lymphoid tissues. G. Harris.
Neurite extension by mouse neuroblast: evidence for two modes of induction. P. Furmanski.



The journal aims to cover the following areas of study: embryonic Differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions *in vivo* and *in vitro*, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Contributions for publication are invited by The Editor.

Editor: Dimitri Viza. Faculté de Médecine Pitié-Salpétrière, Laboratoire d'Immunobiologie, 105 Boulevard de l'Hôpital, 75634 Paris Cédex 13, France.

Editorial Board: E. J. Ambrose, R. Auerbach, J. Brachet, A. Braun, D. A. L. Davies, B. Ephrussi, H. Holtzer, F. Jacob, N. J. Jerne, C. Kafiani, G. Klein, Rita Levi-Montalcini, A. Lwoff, R. G. McKinnell, C. L. Markert, Beatrice Mintz, C. Pavan, B. Pierce, S. Spiegelman, G. Tocchini-Valentini, S. Toivonen, D. Yaffe, T. Yamada.

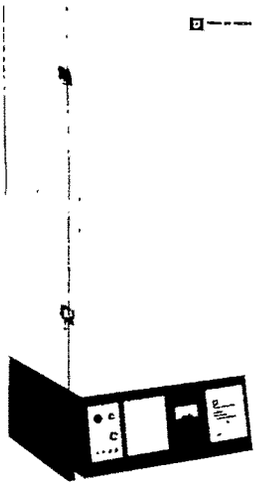
Record Platelet Aggregation

under controlled conditions

NEW DUAL CHANNEL AGGREGATION MODULE — a unique instrument designed to study platelet aggregation of blood plasma. This new dual channel unit allows the researcher to run both a control and an unknown at the same time under identical conditions. Compatible with most recorders.



Features — advanced optics, solid-state circuitry — stable, drift-free operation — precise temperature control — accurately controlled and monitored stirring speed — disposable curvettes and stir bars — and more. Write for brochure and list of references.

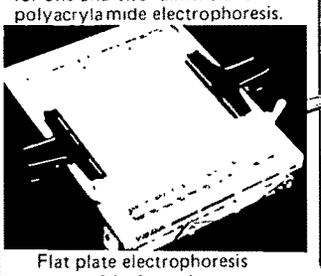
Beneath that attractive exterior there's a heart of cold.

-73°C cold, in a 29° ambient. Guaranteed. 13 cubic feet protected by five-inch foamed-in-place polyurethane insulation, a triple-sealing gasket, and heavy-duty latches. Not a made-over appliance, but a durable, all-steel cold cabinet.

Four separate inner compartments, each with its own transparent door, minimize cabinet exposure to outside air. Easily accessible for technicians of all heights. Wheels from station to station; operates quietly on 115V current. So well insulated you won't need door heaters or gasket heaters. Warms up ever so slowly if your power fails.



Check Forma's 8200 freezer soon.
Or the 8225, which can operate as low as -87°C.
They're even better than they look.
220V, 50 cycle models available.

A new journal starting Spring 1974

Journal of Mathematical Biology

Edited by
H. J. Bremermann,
Berkeley
F. A. Dodge, Jr.,
YorktownHeights,N.Y.
K. P. Hadeler,
Tübingen

Subscription Information:
Volume 1 (4 issues) will appear in 1974:
DM 136,–,
plus postage.
North America:
$63.00, including postage.
(Subscriptions are entered with prepayment only.)

Sample copies are available upon request

The intent of this new journal is to further the cooperation of two major disciplines. In biology there have been significant breakthroughs, e. g. in molecular biology and chemical biodynamics. There is great progress in basic mathematics, computer technology, and numerical techniques, and an abundance of mathematical talent. The mutual understanding and collaboration between biologists and mathematicians is steadily increasing. New mathematical developments are applied in the life sciences. The complexity of biological phenomena in neurobiology, morphogenesis, chemical biodynamics, and genetics is a challenge to mathematics. The gap between the inherent complexity and the tools available is bridged by mathematical models, which are realistic as possible yet simple enough so that inferences can be drawn from them.

Scheduled for Volume 1:

J. C. Bezdek, Numerical taxonomy with fuzzy sets. – C. Foiaş, A biological homology inference from ergodic theory. – K. P. Hadeler, On the equilibrium states in certain selection models. – J. L. Lebowitz, S. I. Rubinow, A theory for the age and generation time distribution of a microbial population. – H. C. Mel, D. A. Ewald, Thermodynamic potentials and evolution towards the stationary state in open systems of far-from-equilibrium chemical reactions: the affinity squared minimum function. – G. Palm, On the selection model for a sex-linked locus. – E. Schäfer, H. Mohr, Irradiance dependency of the phytochrome system in cotyledons of mustard. (Sinapis alba L.). – A. Wörz-Busekros, The zygotic algebra for sex linkage. – H. L. Resnikoff, Differential geometry and color perception I. – A. T. Winfree, Patterns of phase compromise in biological cycles.

Cell.

It's not just another new journal.

The first issue of **Cell**, a new monthly journal of cell and viral biology from The MIT Press, was published in January, and already its astonishing growth, both in circulation and reputation, seems destined to make it one of the most important journals in its field. Edited by Benjamin Lewin, formerly the editor of *Nature New Biology*, **Cell** provides a wide-range journal publishing articles of general interest in molecular biology, cell biology, tumor virology, immunology, genetic development, and other related areas. Papers are refereed as rapidly as possible and those accepted are published within twelve weeks.

Cell also includes an extensive review section. In addition to those reviews with the traditional role of discussing a field in some depth, short reviews give conceptual accounts of recent advances in areas of cellular biology, for the benefit of researchers in other areas. Book reviews and discussions of meetings are also included.

The May issue of Cell will include the following articles and reviews:

Interaction of Regulator Proteins with Recognition Sequences of DNA: Benjamin Lewin

A Measurement of the Sequence Complexity of Polysomal Messenger RNA in Sea Urchin Embryos: Glenn A. Galau, Roy J. Britten, and Eric H. Davidson

Studies on Nascent RNA in Mouse Myeloma: Henry Berger, Jr., and Ru Chih C. Huang

Regulation of Intracellular Protein Breakdown in Stringent and Relaxed Strains of E. coli: Devorah Rafaeli-Eshkol and Avram Hershko

Mutations Affecting Adenine Phosphoribosyl Transferase Activity in Chinese Hamster Cells: Lawrence A. Chasin

Mutants of Cultured Chinese Hamster Cells Deficient in Adenine Phosphoribosyl Transferase: G. E. Jones and P. A. Sargent

Type C Viruses of Baboons: Isolation From Normal Cell Cultures: G. J. Todaro, C. J. Sherr, R. B. Benveniste, and M. M. Lieber

Vesicular Stomatitis Virus Envelope Glycoprotein Alterations Induced By Host Cell Transformations: Sue A. Moyer and Donald F. Summers

Inhibition of Transport Systems In Cultured Rat Hepatoma Cells By Colcemid and Ethanol: Peter G. W. Plagemann and John Erbe

Development of hCG-Sensitivity in The Testis of the Immature Rat: Wolfgang Engel and Joachim Frowein

The June issue of Cell will include the following articles, reviews, and book reviews:

The Gene Numbers Game: J. O. Bishop

Evidence for Genetic Recombination Between Endogenous and Exogenous Mouse RNA Type C Viruses: J. R. Stephenson, G. R. Anderson, S. R. Tronick, and S. A. Aaronson

Increased Protease Levels in Transformed Cells: A Casein Overlay Assay for the Detection of Plasminogen Activator Production: A. R. Goldberg

Changes in Adenylate Cyclase, Cyclic AMP, and Protein Kinase Levels in Chick Myoblasts, and Their Relationship to Differentiation: R. J. Zalin and W. Montague

Induction of a Deoxycytidineless State in Cultured Mammalian Cells by Bromodeoxyuridine: M. Meuth and H. Green

Expression of Thymidine Kinase Variants is a Function of the Replicative State of Cells: R. Adler and B. R. McAuslan

Book Reviews

Among the Protozoologists: S. H. Hutner
Cell Culture—the State of the Art: J. Bard
Ribonucleic Acids in Review: E. M. Scolnick

Subscription Prices
A year's subscription to **Cell** is $70 for individuals in the U.S., Canada, or Pan American Postal Union and $75 for individuals in other countries.
The subscription price for institutions is $100 in the U.S., Canada, or Pan American Postal Union and $105 for institutions in other countries.

Manuscripts and editorial correspondence should be addressed to the Editor or European Editor.

Guide to authors

Nature accepts three types of communications:

● Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

● Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

● 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (*a*) is preferred to e^a if '*a*' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Evidence of hydrophobic interaction in adhesion to tissue—*P. Y. Wang* 367

H_2-receptors in peripheral blood vessels—*D. M. Grennan, P. J. Rooney, E. Gilbertson and W. C. Dick* 368

Binding of concanavalin A and ricin to synaptic junctions of rat brain—*H. Bittiger and H. P. Schnebli* 370

Toxins of *Vibrio cholerae* and *Escherichia coli* stimulate adenyl cyclase in rat fat cells—*E. L. Hewlett, R. L. Guerrant, D. J. Evans, jun. and W. B. Greenough III* 371

Subterminal motor nerve abnormalities in psychotic patients—*H. Y. Meltzer and J. W. Crayton* 373

Effects of bicuculline on functions of inhibition in visual cortex—*D. Rose and C. Blakemore* 375

Constitutivity of the HCG-receptor protein in the testis of rat and man—*J. Frowein and W. Engel* 377

PERKIN-ELMER GAS CHROMATOGRAPH WINS DESIGN COUNCIL AWARD

The Perkin-Elmer Model F30 is the first gas chromatograph to win a Design Council Award for products showing outstanding achievement in engineering design. Developed and manufactured in England this instrument is the most sophisticated routine gas chromatograph available today – and yet one of the simplest to operate.

PERKIN-ELMER LIMITED
POST OFFICE LANE BEACONSFIELD
BUCKINGHAMSHIRE HP9 1QA

TELEX 83257
TELEGRAMS PECO BEACONSFIELD

PERKIN-ELMER

Outstanding in performance as well as original in design the Model F30 has made a great impact in both domestic and export markets. Features such as thermostatted pneumatics, carrier gas flow sensors and 'make up' were totally new in concept when introduced on the Model F30, and together with the reproducibility of the digitally set controls have contributed largely to its success. Introduced in 1971 as a high performance routine instrument the Model F30 was followed in 1973 by the versatile Model F17 and in 1974 by the low priced Model F33, giving Perkin-Elmer a product range unsurpassed throughout the world.

Scientific Instruments
Infrared ultraviolet, fluorescence and atomic absorption spectrophotometers, gas and liquid chromatographs, polarimeters, molecular weight apparatus, differential thermal and elemental analysers, mass, nuclear magnetic resonance and photoelectron spectrometers, electron microscopes and electronic recorders

Portland problems . . .

BRITISH defence research has always been conducted in conditions of obsessive secrecy, and so the news that the Admiralty Underwater Weapons Establishment (AUWE) at Portland was to let selected guests in was a pleasant surprise. In 1968, the Select Committee on Science and Technology had urged wider dissemination of Portland's problems and achievements, and this was their belated response. Dr G. L. Hutchinson, the Director, indicated that he hoped that industry and universities would come into closer relationship with the establishment; he must also have had an eye on the defence review now being conducted. His budget is £9 million which he regarded as inadequate for some of his tasks.

The establishment is responsible for research and development for offensive and defensive naval requirements beneath the ocean surface. Within AUWE's orbit is torpedo homing, data collection in submarines, hydrodynamics, and all manner of other problems not all of which, doubtless, were on view; the greatest problem as far as one can tell is the antisubmarine warfare (ASW) requirement of finding submarines—in particular nuclear submarines—in the complex environment of the oceans. Sound in the kilocycle frequency range is the tool used but it is severely blunted by the sound velocity structure of the oceans which is neither laterally homogeneous, simple to parametrise, nor time invariant. The medium is barely conducive to propagation of sound over distances of more than a few tens of kilometres.

A first look at a new institution may be deceptive. Certainly security still poses enormous problems; one guesses from the unease with which some questions were answered or deflected that many would be glad when the whole thing was over and they could get back to work. There was an indication that open days would not become a regular feature of Portland's life; this, one hopes, is a sentiment which will be strongly resisted by the government, for the establishment has a lot to lose and nothing to gain by returning to obscurity.

The overall impression is somewhat sad. Amongst the exhibits were no surprises of the sort which mark out some laboratories as vigorous. Maybe there was more in what was not shown, but that is unlikely. The argument that the real stuff cannot be unveiled for reasons of security has always rung somewhat false and as likely as not means there is no 'real stuff'.

But there was more to the sadness than that. Many military laboratories all over the world were created in something like their present form in the ten years following the Second World War and recruitment was at its most vigorous at that time. They have all encountered the problems that Portland seems to have—of a now middle-aged professional staff with much experience (in this case of the hostile marine environment) but a diminishing capability for aggressive scientific thinking and yet insufficient other outlets. Universities offer teaching, committee work and administration. Industry simply discards the nonproducers. Government scientific establishments can do none of this.

The results are two-fold. First, the creative ability declines as old solutions to problems are carefully refined whilst new solutions are not perceived rapidly enough. Second, research establishments become steadily less attractive to the brightest young graduates.

How far Portland conforms to this pattern is difficult to tell but all the symptoms are there. In addition, there is the resigned spirit so often manifested in government laboratories—the seeing of decisions as descending from 'our elders and betters' with the unambiguous indication that although elders not betters. There is also the horizontal compartmentalisation of problems—workers are not expected to know nor to take steps to know what is going on down the corridor. The compact rule of security, that the enquirer must not only be cleared but must also have a 'need to know', may cut down on spying but it reduces research creativity alarmingly. It is doubtful that many in Portland have access to enough pieces of, say, ASW research to put together a coherent up-to-date story of present abilities and future prospects. And yet any competent research student constrained from acquiring a global view of his subject would rightly walk out.

The problem of ASW is perhaps insoluble and it may be that this is our greatest guarantee of a measure of strategic stability for the next twenty years. On the other hand, there are many in the academic community who would like to become more involved in matters of defence —more, maybe, than the Ministry of Defence appreciates.

. . . Greenwich solutions

CHARLES II is said to have informed the Royal Society that he was "graciously pleased" with their work on useful problems such as finding the longitude at sea but not with their "childish diversions" such as weighing air. In the next hundred years, with the stimulus of a prize of £20,000, the art of navigation moved from complete ignorance about longitude to precise determination. It is a marvellous tale, always worth another hearing, and Eric Forbes' recent monograph (*The Birth of Navigational Science*, National Maritime Museum, Greenwich) is a good retelling because the role of Tobias Mayer and the method of lunar distances are fully explored.

Latitude is a relatively easy quantity to measure (so few look at the motions of celestial bodies these days that we make no apologies for an elementary exposition). The elevation of the Pole Star above the horizon at night is almost constant. During the day the maximum elevation of the sun also rapidly leads to the latitude. So with rudimentary devices latitude had been roughly determined since the sixteenth century. Longitude is altogether different, as some means of knowing both local time and some standard time, such as Greenwich, is needed. Local time is relatively easy to obtain from midday, and even quite inaccurate clocks can be used with daily corrections. Greenwich time is an altogether different proposition. So serious was the problem to mariners that large cash prizes were offered for its solution by the governments of France, Holland, Spain and Venice in the sixteenth and seventeenth centuries. As early as 1530 two distinct methods had been proposed: one that a high quality clock be carried on a ship, to take Greenwich time along, as it were; the

other that a celestial clock be used such as the steady progression of the Moon amongst the stars.

The two most promising methods—superior clocks and so-called lunar distances—were still far from accurate enough when the British government set up the Board of Longitude in 1714. Standard practice on long voyages was to run down lines of latitude into one's destination, a potentially catastrophic procedure if sailing to an island and unsure whether east or west of it. As late as 1741 Anson in the *Centurion* lost eighty men of scurvy in the twelve days he spent hunting for Juan Fernandez (of course not only were ships often misplaced, so, occasionally, were islands). The Board offered a results-related award—£20,000 for an accuracy of half a degree in longitude at the end of a six-week voyage to the West Indies, £10,000 for an accuracy of a degree. Sir Isaac Newton summarised the problems in making an accurate enough timekeeper—"the Motion of a Ship, the Variation of Heat and Cold, Wet and Dry, and the Difference of Gravity in different Latitudes". An accuracy of about two minutes would be needed at the end of the prescribed sea voyage for a half-degree accuracy, and clearly no pendulum clock would be up to that. Spring-driven clocks had been made as early as 1500 but by 1714 had never been compensated properly for temperature. Lunar distances might take the prize.

On the practical side one had to measure the angular distance between the moon and some prominent zodiacal star. This changes 13° in every 24 hours, so the invention in the 1720s of the reflecting octant with an angular accuracy of 1′ implied that if the lunar motion were perfectly tabulated, time by the Moon could be accurate to about two minutes once atmospheric refraction and geocentric parallax were allowed for. Two minutes of time is half a degree of longitude so the prize was in sight, at least if the tables could be perfected. It was to this that Tobias Mayer of Nuremberg and Göttingen most successfully devoted fifteen years from 1747.

Mayer was a cartographer and his interest in astronomical determinations of longitude came not from any nautical experience (he never even saw the sea) but from a desire to improve land surveying in Germany. He realised as he searched for higher accuracy that existing lunar data was unreliable and even that some of the stellar positions were unsatisfactory. Having read Euler on analysis and mechanics he ventured into the theory of the Moon's motion around a spheroidal Earth.

His first tables of the motions of the Moon in 1752 were criticised for discrepancies and for a certain inscrutability but by 1754 he had shown that the discrepancies were in contemporary star tables, and the usefulness of the tables for longitude determination was demonstrated. Euler now persuaded him to go for the prize money which he did in a Memorial to the Lords of the Admiralty beginning: "Having by indefatigable application and a great deal of trouble found out the longitude at sea . . . "

His work was well received in London, but the Board of Longitude delayed and Mayer died before a decision was made. Nevil Maskelyne, Astronomer Royal, used the tables with success on a voyage to St Helena in 1761 to observe a transit of Venus, and there was general agreement that Mayer's widow merited the £10,000 prize. The Board thought otherwise (they were probably somewhat embarrassed by their simultaneous encouragement of Harrison and his chronometers) and eventually awarded her only £3,000. This grudging acknowledgement did not inhibit the Commissioners of Longitude from using Tobias Mayer's tables to generate the first Nautical Almanac for 1767. But now the potentially more accurate chronometer, untied to problems of the Earth's rotation and the Moon's complex orbit, began to come to the fore.

John Harrison (1693–1776) stands out as a clock maker head and shoulders above his contemporaries. He came to London in 1728 with two inventions which were to start him on a lifetime of battling with temperature fluctuations and poor lubrication—the 'gridiron' pendulum of brass and steel rods and the 'grasshopper' escapement which required no oiling. His first clock H1, was tested so effectively on a voyage home from Lisbon in 1736 that Harrison, having estimated the position one and a half degrees west of the calculation by dead reckoning was proved right on landfall.

The money was not that easily won. The Board helped Harrison financially, but the Spanish wars and his own self criticism prevented a direct assault being made on the prize until 1761 by which time Harrison had built two other chronometers with which he was not totally satisfied, and now produced the watch H4, a mere five inches across. H4, surely the finest watch ever, was taken to Jamaica in an inconclusive trial, but in 1763 was tested again and showed an error of less than one tenth of a second per day. This should have brought Harrison his £20,000. The Board paid half but demanded that he secure his second £10,000 by showing that H4 could be made by others. Eventually George III exerted pressure and in 1773 Harrison received another £8,750.

Go to Greenwich to see Harrison's chronometers. They are displayed in a serene room almost inaccessible to the casual visitor like the Lady Chapel of some cathedral. The display is superb, as the big clanking clocks come on you one by one down the room. And then suddenly there is a small ticking watch, H4. The atmosphere is almost religious, and the visual surprise will live with you for a long time.

100 years ago

Colonel Gordon left Khartoum on March 21, and in his last letter from Fashoda, 10° N., he touches on some of the scenes on the banks of the river—the storks, which he was in the habit of seeing arrive on the Danube in April, laying back their heads between their wings and clapping their backs in joy at their return to their old nests on the houses, now wild and amongst the crocodiles 2,000 miles away from Turkey; the monkeys coming down to drink at the edge of the river, with their long tails, like swords, standing stiff up over their backs; the hippos and the crocodiles. Such scenes to a lover of nature, as Col. Gordon is, doubtless would serve to make up in some measure for the loss of civilised society and comforts.

Does cancer research have realistic aims?

The Imperial Cancer Research Fund tries with its 1973 report, recently published, to appeal to a wider audience. Brian Ford takes a look at the report and at broader issues in cancer research.

CANCER research is a blend, not altogether a happy one, of the assured with the uncertain, the esoteric with the mundane; yet in recent years some remarkable improvements in survival rates have been achieved in fields that include breast cancer, leukaemia and the lymphomas. That alone is sufficient to refute allegations that this speciality is uniquely able to consume public funding for little tangible benefit. Successes in specific areas are, however, not themselves a guarantee that priorities are correct or that courses of action have been chosen for valid criteria. The latest report of the Imperial Cancer Research Fund (Lincoln's Inn Fields, London WC2) throws an interesting light on the advancing front of progress, and mirrors some deficiencies in the philosophy that underlies it.

Past reports have been issued by the fund in a different form. As the Foreword acknowledges, they have been an unsatisfactory mixture of facts, figures and data presented (particularly where clinical findings and research are concerned) in the specialist form least likely to attract interest or even understanding from the outside reader. The survey for 1973 is therefore novel in approach, for it embraces three specific and distinct areas of interest: the accounts (which are bound as a separate volume), the research reports as such and the Director's assessment. There has been a deliberate attempt to word this introductory section carefully so that it may be assimilable to the intelligent outsider (who is described as a 'non-scientist' by the Foreword, but in this era of isolationist specialisation is as likely to be a psychologist or physicist) and Michael Stoker has taken the brave step of using his easy manner and flow of commonplace English to accomplish the task. For so long has it been widely assumed that understandable terminology and uncomplicated syntax are indicators of superficiality in approach, that this step is perhaps doubly notable. Yet in some respects, by casting a more direct light on the state of the art, it is a less than satisfactory exercise.

He draws a close parallel between the immune response that may be invoked against malignant cells and that seem to act "against measles". Similarly far-fetched analogies are becoming popular (indeed the Nature-Times News Service report dated April 22, 1974, draws a similar parallel) yet it is arguably unrealistic. Surely the infective invasion of susceptible tissues by a transmissable viral genome is operationally distinct from neoplastic transformation, and the quest for a genotypically polyvalent vaccine, as it were, must be a different kettle of fish from the development of measles immunisation. One looks back to the trial-and-error attempts of Jenner to experiment with vaccinia and Pasteur with rabies, both by good fortune working with material which responded uniquely to their techniques though neither had much reason to suppose it would do so; and one assumes there is something more predictable, less metaphysical, about modern medical methodology. Yet here we are, in the 1970s, with electroshock in the psychiatric hospitals and vaccine-shock in oncology, hopefully injecting BCG or irradiated leukaemic blast cells, in the hope of gingering up the immunological sensitivities of a cancer patient.

In Stoker's words it looks sound enough: "The vaccine is made from leukaemic blood from another patient, which is slightly different from the recipient's own blood and may, therefore, give an additional boost to the defences". Yet it is this very clarity which reveals the extent to which our knowledge is clouded and incomplete.

ICRF headquarters in London

There are many other fields of investigation in which the dearth of detailed knowledge, and the inadequacy of many orthodox beliefs, is demonstrated. The report mentions that Rubens and Dulbecco have investigated the use of cytotoxic compounds adsorbed onto tumour-specific antibodies, the principle being to utilise the antibody as a vehicle for the drug, only to find that the loose covalent association that was assumed did not, apparently, occur in their trials. It now seems that the increase in susceptibility of the transformed cells is coincidentally induced by the presence of antibody; how remains uncertain.

Though some of the practical problems of cancer management remain poorly understood, the study of what we might in the broad sense term oncogenetics is inspiring. So too is the interest in conceptualising about cell growth. I believe it is helpful to construct greater models by which to account for the lesser datum; holistic concepts through which to marry reductionist dogmas. In this respect it is heartening to see the work which Martin and his colleagues have under way, which construct novel interpretations of the dynamic status of mature cell communities; models that are not profound and whose principal benefit lies in their being far from complex, but which provide an intellectual synthesis of observed phenomena.

Growth-rate regulatory mechanisms are what cancer is all about, and it is fitting that one of the leading ICRF groups should be the Department of Cell Regulation. Yet, when our understanding of these mechanisms is so profoundly complex in some respects, how surprising it is that Stoker can demonstrate the simple fact that boundary layer gradients may be as important as cell-to-cell contact in regulating cell growth rates. This contrast between the detail of our understanding in some respects, and our ignorance of far more fundamental, practical issues in others, can be illustrated by other reports in the document. Though it is now beginning to seem possible that we may be able to screen urine samples as a means of detecting those patients peculiarly susceptible to breast cancer, it is still not known whether radical mastectomy or wide excision are preferable in the early stages of the disease. Here too we see progressive developments in one aspect of a discipline

Research in progress at St Bartholomew's Hospital, London, where the Imperial Cancer Research Fund established a Professorial Chair in Medical Oncology in 1971.

contrasting with ignorance of a seemingly elementary nature in another.

In certain respects the sense of imbalance that parts of the ICRF report engender are no more than a mirror of the greater problems faced by modern science. To rely, in some primitive Baconian sense, on observing phenomena and then adopting the correctly self-critical mode advocated by the followers of Professor Popper, seems to be the only true path to objectivity and insight. Too often it tends, instead, to blind one to the true relationships between the larger fragments of science, and it conveniently ignores the weaknesses and foibles of human nature. I believe we should now recognise the inability of modern scientific research to fulfil its function adequately by relying solely on what one might term inspirational research. Perhaps we need something of what the Americans would term the 'project' approach, in which teams or individuals are asked to prosecute a given line of investigation which fitted into the whole.

The argument against this is that in this way we tend towards the dictatorial direction of research. What we seem to forget is that research is being surely directed at the moment, but directed by whim, by fancy, by inclination; it is directed by current trends, by the concensus paradigm subconsciously obeyed by an introspective discipline of science; and it is directed by the distribution of funds and support. Though there is no need to dictate science policy, or to set the sights of science at some invisible target, there is certainly room for a little calculated realism somewhere in the mix.

Even though we pay little attention to the criteria by which our research priorities are selected, they certainly exist. To utilise a framework of agreed values to supplement—though in no sense replace—'personal fulfilment' guidelines is more likely to bring us nearer the truth than shots in the dark, no matter how inspired the marksman. Though it is undeniably true that free-wheeling chance gave us *Penicillium notatum* and the earlier discovery of antibiosis, it was the directed research of wartime that gave the world penicillin and the antibiotic age. In an area such as cancer research, where the main concern of all is to bring about an increase in knowledge, unless they or their relatives are suffering from the disease, when the prime requirement is seen as the saving of life; here more than anywhere we need guidance by concensus and objective-setting as a supplement to inspiration.

To speak of cost-effectiveness in research is irksome—until we realise how costly it is, and how badly civilisation needs the effects.

If we have to pick out one example of an individual revelation from the ICRF report, there can be no better example than the discovery of a demonstrable difference between the cell surface in normal and transformed tissues, namely the absence of a normally-present protein from the surface of malignant cells. This has been the work of Richard Hynes in the Department of Tumour Virology, and is a sound and hopeful advance. Indeed it is in virological research that the ICRF has perhaps its greatest claim to fame, and around which at least four of the groups base their work. Yet man seems to show few signs of suffering from virus-induced tumours, and current estimates suggest that 60–90% of all malignancies in man are caused by chemical carcinogens. Should one suggest that—if resources are limited—more attention should be paid to the practical problems of patient care in hospitals and at home?

We still know little about cells in communities. A model of histological or developmental normality—cell sociology, one might say—is at least as important in understanding malignancy as would be a comprehensive understanding of a single cell. If we are to promulgate pure research, ought it not to concern itself with relatively unexplored avenues such as these?

It is often said that in cancer one cannot experiment on humans. But one does, of course, perpetually in a manner which (though entirely justifiable and ethical) must surely seem incongruous alongside specialised research in other fields. How is it there is still the scent of alchemy in the air where much chemotherapy is concerned, utilising drugs of high potency but uncertain action in an empirical and almost haphazard manner? Should the arm be immobilised after breast surgery or allowed freedom of movement as an aid to fluid drainage? Are steroids helpful in the therapy of malignant disease? These questions (which seem fundamental indeed alongside specialised virus research) are only now being resolved, by experimental trial.

When there are many short term, immediate questions to be answered, is it entirely justifiable to press ahead in such detail on animal research based on cancer models that are not apparent in mankind? Perhaps we should take heed of the comments in last year's report from the International Agency for Research on Cancer in Lyon concerning the near impossibility of extrapolating the mass of data from animals to man. Indeed, is not the problem of cancer research that we know too much: we have too many data and too few conceptual pegs on which to hang them? And is the balance of cancer research entirely fair to the patient?

INSTITUTE OF ... Date ...

US at chemical war crossroads

Colin Norman, Washington

THE prospects for international control of chemical weapons could well hang on the results of an intensive review of the United States chemical warfare policy now being conducted by the Nixon administration. It is the first such review for nearly five years.

Begun quietly by the National Security Council (NSC) in December last year, the review is a two-pronged study, first of an impasse which for four years has prevented the United States from ratifying the most important chemical weapons treaty ever negotiated—the so-called Geneva Protocol of 1925, which bans the first use of chemical weapons in war. And, at the same time, the NSC is taking a close look at the Pentagon's plans to modernise its existing nerve gas stockpiles by replacing them with a new generation of chemical weapons called binaries. According to Adminstration spokesmen who testified on nerve gas policies before a congressional subcommittee earlier this month, the review should be completed in the next few months.

Meanwhile, Congress is also faced with an important decision in the chemical warfare area, for the Pentagon has already requested approval of funds to begin producing binary weapons at the Pine Bluff arsenal in Arkansas. A decision must be made this summer on whether or not those funds will be approved.

These reviews and decisions are taking place against a backdrop of international negotiations being conducted in Geneva under the auspices of the 26-nation conference of the Committee on Disarmament (CCD), the ultimate aim of which is to negotiate a treaty banning not only the use of chemical weapons in war but also their production and stockpiling. In other words, the goal is complete worldwide disarmament. What happens in Washington in the next few months will be crucial to the outcome of those negotiations.

At present, the official Administration policy on chemical warfare, as outlined by President Nixon in a statement in November 1969, is that the United States will never be the first to use chemical weapons in a war, and that it has renounced entirely the use, production and stockpiling of bacteriological weapons. Coupled with the no-first-use policy, however, is the understanding that in the absence of worldwide chemical disarmament, the United States army needs to maintain extensive stockpiles of nerve gases to deter other countries from initiating chemical warfare or, if deterrence fails, so that the United States can retaliate in kind. For those reasons, some 45 million pounds of nerve gases are now stockpiled in bases throughout the United States, in Johnston Island in the Pacific, and at one location in Germany.

Unfortunately, however, since the United States has never ratified the Geneva Protocol the policy of no first use of chemical weapons is nothing more than a promise, and until the protocol is ratified, United States intentions will never have the force of international law. At present, ratification is bogged down in a dispute between the Administration and the Senate Foreign Relations Committee over the Administration's interpretation of the terms of the protocol. It will be crucial to the outcome of the CCD talks that this impasse be broken.

The nub of the matter is that when President Nixon submitted the protocol to the Senate for approval in 1970, he did so with the express understanding that riot control agents and herbicides are not included in its provisions. In other words, even if the United States government formally ratifies the protocol it would still consider itself free to use those agents in warfare—in fact the United States army was doing just that in Vietnam at the time Nixon submitted the protocol to the Senate. The Senate Foreign Relations Committee argued, however, that the protocol should include all chemical weapons and it is refusing to put the matter to a vote in the full Senate until the Adminstration backs down from its interpretation.

There the issue has rested for the past four years, but at least the NSC is now taking a close look at the Administration's position. Whether a complete change of mind will ensue from the review is, however, doubtful to judge by statements made by Administration officials who testified before a subcommittee of the House Foreign Affairs Committee earlier this month. Mr Amos A. Jordan, Assistant Secretary for Defense for International Security, argued that herbicides and riot control agents played a valuable and "humane" role in the Vietnam war, for example, and he said that the Administration's position has not changed.

Failure to ratify the Geneva Protocol is understandably viewed within the CCD talks as a severe stumbling block in the path of efforts to secure a more extensive treaty which would outlaw chemical weapons entirely. Furthermore, a treaty outlawing the production, use and stockpiling of biological weapons, which was negotiated at the CCD talks a couple of years ago, is also held up in the Senate Foreign Relations Committee awaiting a final resolution of the Geneva Protocol dispute.

That is bad enough, but according to a number of observers, the Pentagon's plans to develop binary weapons could eventually kill the CCD talks entirely. Binary weapons have been under development by the United States army for the past ten years or more, but they are now coming up for a number of crucial decisions. In short, the weapons consist of two "relatively non-toxic" chemical components which form a lethal nerve gas when they are mixed together. The idea is that they would be kept apart until they are required for use, and they would then be fed into separate compartments in a shell and allowed to mix only when the shell is safely on its way to the target.

The Pentagon's argument for binaries is simple enough. Since the weapons are safe to store, produce and transport, they form ideal replacements for the existing ageing stockpiles of nerve gases. According to official army statements, nerve gas munitions have shelf life of only 15 years, and thus existing stock of filled weapons will have to be replaced by about 1985. Consequently, in September last year, the army began to tout the advantages of binary weapons in public statements and in congressional testimony, and it has now asked Congress to approve a request for $5.8 million to begin production of 155-mm binary-equipped artillery shells. That request is now under consideration—in secret—by a Congressional Appropriations Committee: it is being hinted that the request is running into some trouble.

The binary programme is being opposed by a small number of congressmen concerned chiefly over the possibly damaging effects of a massive new chemical weapons programme on the Geneva CCD talks, and they seem to be picking up some influential support from a few conservatives connected with military affairs—a sign, perhaps, of the way the wind is blowing, is that the House Armed Services Committee recently voted to cut about $1.9 million from the Pentagon's request for research and development related to binaries (this, it should be noted, would be an entirely separate demand from the demand for production funds).

One particularly effective argument, which surfaced during the House Foreign Affairs Committee hearing earlier this month, is that the Administration is now conducting an "urgent review" of the binary programme itself, and that Congress should therefore delay approving the Pentagon's request for production funding, at least until the National Security Council has decided whether or not the Administration is actually in favour of the programme. At present the Congress is placed in the position of deciding whether or not to provide money for a programme which may be killed off by executive fiat at some future date—a situation that would arise only in the highly sensitive region of defence spending, and which gives substance, to the view that there is little executive scrutiny of the Pentagon's annual demands before their submission to the Congress.

Although that argument may ultimately carry most weight in the Congress, it became clear during the House hearings that the binary programme could well be in trouble for a variety of other reasons, and that there is a division of opinion actually within the Administration on the merits of pushing ahead with a chemical weapons programme of any variety at the current stage of the Geneva talks. The NSC review of the binary programme will inevitably be subjected to some critical 'input' from the Arms Control and Disarmament Agency, which has admitted serious disquiet over the possibility of a pro-binary decision damaging—perhaps fatally—the CCD discussions. Dr Fred Ikle, Director of ACDA for the past year, said, under heavy questioning from the commitee chairman last week that: "It is my judgment, based on arms control considerations—and this is a personal view—that at this time the pros and cons come out in favour of not going into production (of binaries)".

The military view, as expressed by Mr Jordan, is that present nerve gas stockpiles "do not fully provide the capability we believe is necessary to adequately support all United States forces in case chemical warfare is used against us. Binaries," he said, "provide significant operational and safety advantages over any other known approach which could have been selected for modernisation."

The situation is therefore the familiar one of the official United States negotiating position being in favour of disarmament, yet at the same time the Pentagon is pushing for a new weapons programme. According to Representative Patricia Schroeder, who attended the CCD talks last year as an official United States observer, "Where many nations last summer simply regarded the United States as having assigned a rather low priority to CCD activities, by mid-March, as the 26 reconvened, one of the more influential western delegates, Dr Alfonso Garcia Robles, leader of the Mexican delegation, went so far as to suggest that we plan to trigger a chemical arms race."

Another factor which has recently been injected into the binary debate—and one which could ultimately prove decisive—is the potential opposition of Western European Governments to the programme. In fact, Mr Leon Sloss, Assistant Secretary of State for Political-military Affairs, admitted under questioning by the House Foreign Affairs Committee that the binary programme is running into some diplomatic difficulties.

The reason is simple. Binary weapons make sense only if they are deployed in forward positions, ready to retaliate against an aggressor who initiates chemical warfare. In other words, nerve gases stored in depots in the United States would be of little use as quick response weapons against the Soviet Union, and the only place it makes sense to keep the weapons is in Europe. Sloss refused to discuss the subject in open session, but admitted that any attempt to expand nerve gas stocks in Western Europe would run into difficulty.

Some British observers feel that the outcome of all this will be that the Adminstration will decide that the programme is not worth the diplomatic storm that it may cause and that it will eventually be stopped. But sources on Capitol Hill, while remaining moderately optimistic, believe that the issue is far from decided.

Another refusal to join the NAS

For most American scientists, election to membership of the National Academy of Sciences (NAS) is regarded as an accolade second only, perhaps, to being awarded the Nobel Prize. But during the past four years, two scientists have resigned from the august body, and two others have refused to accept membership when it was offered to them. The chief complaint all four have raised is the academy's close involvement with the research programmes of the Department of Defense.

The latest to decline association with the academy is Richard Levins, a mathematical biologist from the University of Chicago, who was elected to the Academy at the general meeting in April. Levins turned down the offer in a letter dated May 10, stating that his "first and most urgent concern is the continuing participation of the academy in military matters".

Levins also sharply criticised the policies of the academy's President, Philip Handler, but he argued that the organisation's connections with the military are "not the result of a perversion of the academy's nature by Phillip [*sic*] Handler or his predecessors, but of a faithful interpretation of its charter and traditions".

The academy's charter, received from President Abraham Lincoln, specifically gives it the role of advising the government, and Levins therefore argues that it would be self defeating to accept membership in the academy and then try to reform from the inside. His letter states: "I cannot hope to remedy this situation by planning with other colleagues to replace Mr Handler with a more liberal president, or by manoeuvring to restore the NAS to its true mission: it is performing its true mission, and I find that mission repugnant."

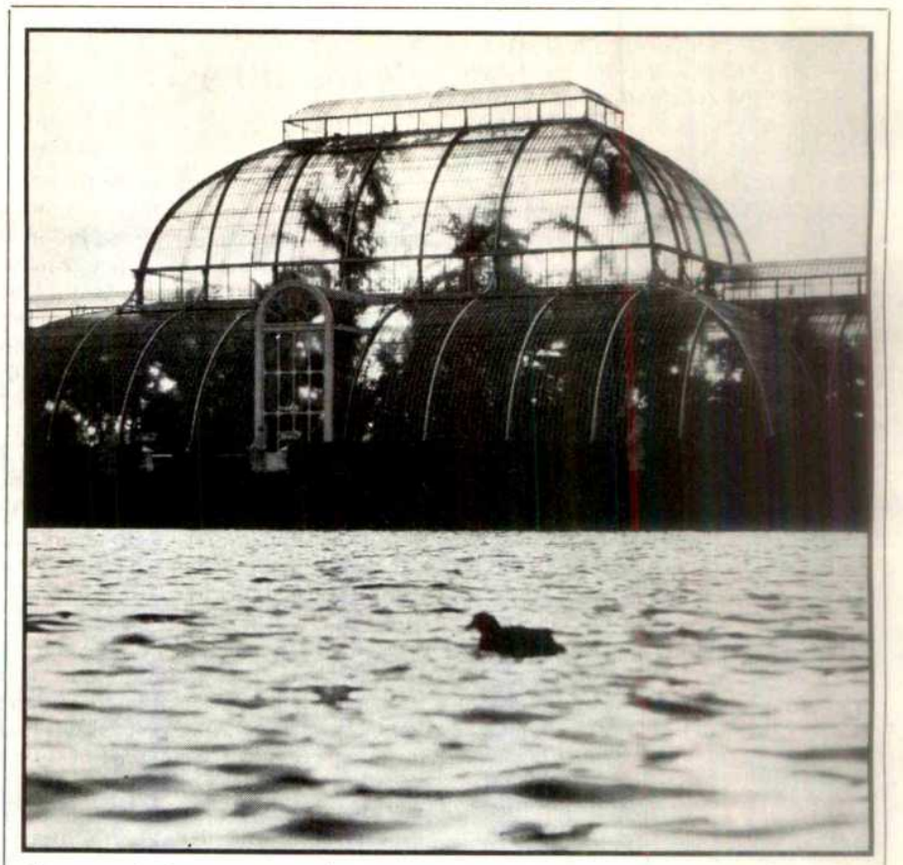
Levins specifically attacks Handler for trying to "weaken any criticisms of the military, as he did in his covering letter (to the academy's report on herbicide damage in Vietnam), where among other things he dismisses the evidence of damage to human health and of death caused by herbicides."

For his part, Handler claims that the amount of classified work undertaken by the academy has declined during the past few years. He stated in his annual report to the membership that about 5% of the funds funnelled through the academy this year were concerned with that resulted in the printing of classified reports.

Be that as it may, Levins and others who have attacked the academy for its association with the military would like to see the organisation completely sever its ties with the Department of Defense. In refusing to accept membership of the academy, Levins is following a precedent set by Dr George Field, a Harvard astronomer.

State of the world: IISS reports

"ALMOST medieval turbulence under a nuclear umbrella", is how the International Institute of Strategic Studies' (IISS) annual report for 1973 describes the military and political scene last year (IISS, 18 Adam Street, London WC2). In a year marked by the withdrawal of the United States from Vietnam, a commitment between President Nixon and Secretary Brezhnev to negotiate a SALT II agreement, the downthrow of President Allende, the Middle East War, the appearance of the oil weapon and ominous creakings in unity not only within Europe but with the United States, the epithet is well deserved.



The greatest strategic development was undoubtedly the use of oil as a weapon which "opened up prospects of entirely new political balances". The quadrupling within a year of oil prices led to Dr Kissinger's proposal for an Energy Action Group, but there were many defections from the united front that was hoped for as western Europe and Japan pursued bilateral deals with oil producers; the ingredients of many of these included arms sales. Already in the eighteen months prior to the October war nearly $5,000 million worth of arms deals had been made with Persian Gulf states—mainly Iran and Saudi Arabia. Iran, in particular, sees threats both internal and external—indeed there are potential dangers on all sides except from Pakistan. The IISS finds it difficult to predict the military future in the Gulf, so complex is the scene. On the one hand armed-to-the-teeth means bloody conflict; on the other, the strength of Iran and Saudi Arabia means stability. A familiar problem for strategists.

The prospects for SALT II are gloomy, as United States–Soviet tensions grew in 1973. There are some sticky problems for negotiators. In August the United States announced MIRV tests had begun in the Soviet Union thus starting the process by which American qualitative superiority though with numerical inferiority in missiles is eroded. And ultimately the accuracies of land-based missiles are so great that if the number of such missiles possessed by one side exceeds that of the other, first strike by the bigger force against the other side's launchers as good as ensures missile victory. The United States is believed to be aiming in SALT II for some sort of numerical equality with limited freedom to mix missiles. This, of course, leaves the American bomber superiority untouched. The Soviet Union is said to have responded that numerical equality would require the dismantling of American Forward-based Systems such as European submarine bases. She also proposed a prohibition on further research and development of bombers, cruise missiles, penetration aids and air-to-surface nuclear missiles. "Outrageous", said the United States.

The problem for the 1990s is the submarines, the institute believes. Much will hang on breakthroughs, if any, in anti-submarine warfare technology, and there are various actions that could be taken to ensure submarine invulnerability. Continuous tracking of submarines could be prohibited, as could large scale sonar installations. Sanctuaries could be provided for submarines. This is the stuff of arms control in the late 1970s and the sooner it is widely discussed the better.

Will the Soviet Union attack China in 1974? The IISS sees this as a serious option for Soviet policy, but concludes that the days are over when a surgical strike against Chinese nuclear facilities would have destroyed the country's weapons programme. Further, China now has more allies, and is capable of inflicting some damage on Soviet cities.

The troubles of Angola, Mozambique, Rhodesia, Namibia and South Africa with insurgents are given four pages, the Northern Ireland troubles not a word. A pity; a brief analysis in the IISS's lucid style would have helped.

Kew: the Palm House

VISITORS had an opportunity to see the other side of Kew when the Royal Botanic Gardens held its open days recently, and the laboratories, library and herbarium were open to the public. The Director, Professor J. Heslop-Harrison, stressed the importance of the gardens as a repository for living wild plant species. The plant kingdom is in retreat, he said, and about a tenth of known angiosperm species are in grave danger. By the end of the century half of these would almost certainly be extinct. As part of a worldwide effort to conserve this fast disappearing genetic resource, a seed bank has already been set up which he hopes will eventually form the core of a national seed bank comparable with those in Leningrad and Colorado. Equally as disastrous as the disappearance of individual species is the destruction of large areas of natural habitat by man's expansion. Professor Heslop-Harrison said that although the general public is now sympathetic to the idea of wildlife conservation the less glamorous concept of vegetation conservation is difficult to communicate, although of prime importance. If you want to save the tiger, he said, first save the teak forests in which it lives. In the gardens themselves, the Temperate House, designed by Decimus Burton and built between 1860 and the 1890s is now being completely restored and renovated as was the Palm House some years ago.

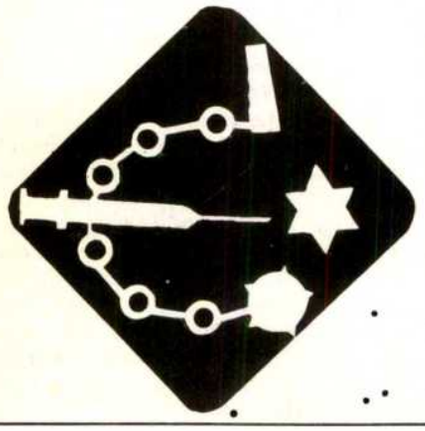
CIA comes clean, almost

John Hall

EUROPEAN manufacturers of PVC are to spend at least £4 million on major plant modification where workers are liable to come into contact with vinyl chloride monomer (VCM). The move follows reports earlier this year that exposure to VCM had caused the deaths of plastics workers in the UK and the United States. Subsequent enquiries have revealed 18 cases of liver cancer among PVC workers—12 in the United States, one in Britain and possibly five in Europe. Inronically, the very rarity of the angiosarcoma involved has allowed researchers to say so concretely that it was caused in the occupational environment. Since no other chemical agent is known to produce angiosarcoma so directly it is difficult for the industry's scientists to look for outside causes, whereas a common or garden lung cancer might easily have been attributed to any number of external factors.

The Chemical Industries Association (CIA), which represents the big four British plastics producers involved in the affair, is at great pains to point out the highly moral way in which the companies have responded to the news that VCM is a bad smell in a production process which looks like a bed of roses profit-wise. Not only did the manufacturers sponsor Maltoni's Bologna programme (which put the finger on VCM) but having found themselves on the spot when the unpleasant tidings broke earlier this year they have in the space of three months reduced airborne VCM concentrations from 150ppm to 50ppm in polymerisation plants, and to about 5ppm on the actual VCM production line. And this when the legal limit stands at 200ppm. It should be noted on the other hand that the 200ppm limit existed simply as an anti fire and explosion safeguard before anybody had any inkling that the stuff was no good for the liver.

In those days, ladies were spraying their curls with lacquer carried on pressurised jets of VCM from candy-coloured aerosols, nobody turned a hair at the thought of orange pop coming home in PVC bottles and an American liquor company was even planning to market the hard stuff in PVC packaged doses. They ran a programme just to see if alcohol was affected by contact with the plastic, and the answer was that it was OK except that it seemed to leach out the VCM. Nobody knew VCM was bad news then, but the liquor people ditched the idea to be on the safe side.



VCM hair lacquer is now a thing of the past, but the pop bottling and food packaging business is still booming, and the CIA's men recently pointed out that this was because the amount of VCM absorbed from PVC packaging in the diet of your average man was in order of 0.001ppm, and that at this meagre rate of absorption your average man would need to be around for 50,000 years if he wanted to absorb an ounce of VCM. What's more, they remarked, there was no evidence that absorption through the gut rather than through the lungs was in any way harmful. They did not give any indication of what your heavy pop-swagger might expect by way of a daily dosage, or indeed any indication of what dose might be considered lethal, and what safe.

On this last question—the point at which it is safe to absorb a noxious substance and the degree to which an essential industry can divert its energies to eliminating that substance from the air which its workforce breathes—the CIA has struck a philosophical note. Quite correctly, they point out that PVC is not a luxury product, but a major industrial material which is an integral part of modern life. The car industry, coal mining, domestic and industrial building, water distribution, gramophone record production and various other blessings of civilisation depend upon a ready supply of PVC.

If society demands an absolute zero risk for the 2,000-odd men working on PVC production, then this could be met only by ensuring absolute zero exposures, and since this is not a practical proposition, then the producers would have to stop producing, and life as we know and love it would grind to a halt. With improvements in valves and pipe joints carying the pressurised gas concentrations as low as 10ppm may be achieved in existing plants, and in entirely new plants, using the most modern technology, 5ppm might be achieved. This, says the CIA, is probably safe, and in any case achievements beyond this point are not conceivable, and so it's up to society to say its piece. If perfection is demanded, the wheels of industry stop turning; if something a little less will do while research proceeds, then we can have our drain pipes and cable covering. And waxing ever so slightly metaphysical, the chairman of the CIA's VCM Committee, Dr A. W. Barnes even volunteered the opinion that five parts per million was arguably closer to nothing than to something, which is stretching public relations to breaking point, even if you are speaking for the combined interests of ICI, BP, Vinatex and British Industrial Plastics.

Red badge of protest

from our Soviet Correspondent

ON the occasion of the great international celebration-that-never-was of the 250th anniversary of the Soviet Academy of Sciences (or, more correctly, of the old Russian Imperial Academy which it replaced), a small, but significant, "celebration" of the event was held in London by the Medical and Scientific Committee for Soviet Jewry.

The symbol of the meeting, distributed to the participants in the form of a lapel badge, was a redrawing of the official emblem of the Soviet Union—in which the sickle has become a ball and chain, and the hammer the new, scientific and sophisticated weapon of restraining dissidents, the hypodermic. This theme of the repression of the scientific and intellectual community, especially of those members of it who wish to emigrate from the Soviet Union, formed the basis of the address by Heinz Woolf, who compared the current Soviet policy to that of Ivan the Terrible, who, after St Basil's Cathedral had been completed, had the architect blinded so that no else might commission a similar masterpiece. The current Soviet measures, dismissal and harassment of those scientists who wish to emigrate to Israel, merely continues the same tradition of blocking a brain drain.

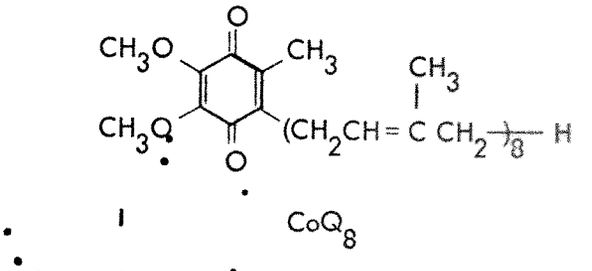
A lively discussion followed, on the role which scientific societies and individual scientists outside the Soviet Union can and should play in countering this policy, and the sensitivity of the Soviet authorities to criticism from bodies like the "Royal" Societies and Colleges or publications like *The Times* and *Nature* which they feel to have a certain official or quasi-official status, was particularly stressed as a potential means of counter-attack.

news and views

Recurrent Mach

A STUDENT of the science of science might find it entertaining to try to discover what it is that reawakens interest in Mach's principle every three or four years, why each ingenious suggestion on the subject has almost no effect upon any subsequent ingenious suggestion—except possibly to stimulate the attempt to be more ingenious—and above all why nobody ever actually states Mach's principle. All of which points seem to be instructively illustrated by the article "Relative-distance Machian Theories" by Barbour in this issue of *Nature*. It does seem to be a few years since at any rate *Nature* carried a contribution on the subject: Barbour's suggestion is ingenious and it does not make use of any previous work; he starts from an assertion of something that "Mach's principle, in essence, requires", and he proceeds to treat this requirement itself as a "postulate". But, once again, no statement of Mach's principle! And there never can be a statement of Mach's principle until somebody discloses that Mach actually stated a principle, and in fact nobody has done this. Mach discussed this problem of inertia in a general way, and he seems to have had some idea that inertia depends upon matter in the Universe in the large. But anybody who wants to go further does have to state his own "postulate" because Mach does not help him.

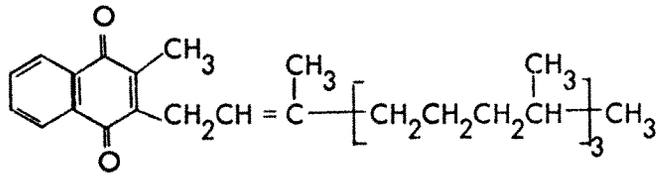
Inertia in the technical sense is a notion of Newtonian physics. Before Newton, the systems of Ptolemy, Copernicus and Kepler each treated a whole Universe—in a very simplified way, of course. Wonderful as they were, they were arid when it came to solving any new problem. Newton came along and said, in effect, that we can break the Universe up—divide and conquer; we may take any small part of the Universe and assert that a frame of reference exists such that the part obeys laws of motion which take certain forms (Newton's laws as usually stated) when this frame is used. The frame of reference—any inertial frame will serve— is the rest of the Universe in the model. Incidentally, it can be seen at once why the Newtonian treatment cannot apply strictly to the whole Universe, because the treatment depends upon this partition of the Universe. Then Mach came along and, so to say working from the opposite end, redetected what Newton had done. From one point of view, it was no great achievement to suggest that an inertial frame might have something to do with the Universe in the large, when all the time the inertial frame is the Universe in the large. From another point of view, Mach did something great in making people wonder why the Newtonian treatment is so successful. People are still wondering about this, and Barbour's paper is an obviously interesting endeavour to push it back to more rudimentary postulates. It might be inappropriate here to discuss details, since he remarks that he is preparing a paper on a different model with more interesting properties.



There is still the general question as to whether such ideas carry over into relativistic models. Barbour evidently believes that his treatment will extend to special relativity; this would be natural, for special relativity also is founded upon the use of inertial frames. It is outside his present scope to say much about general relativity. In general relativity, however, every problem produces an entire universe (in general, not an interesting one); so there is no Newtonian partition and therefore Mach's problem does not arise in the same way. Some writers have indeed, produced sophisticated criteria as to whether any particular general relativity model is "Machian" or not, but this seems to be somewhat far from Barbour's interpretation of "Machian".

W. H. McCREA

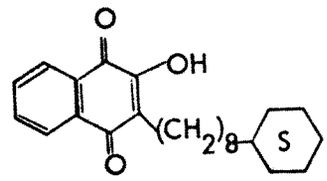
Possible new antimalarial drugs



ALTHOUGH it is well established that malaria parasites inside host red blood cells utilise glucose, the extent to which this process provides the parasites with energy has been little explored. One of the technical problems hindering such an investigation was the difficulty of distinguishing between the biochemical processes of the intracellular parasite and those of the host cell. Until recently much effort was directed towards separating the parasite from host erythrocytes and from other cellular blood elements, particularly white cells and platelets, the activities of which could invalidate biochemical assays of, for example, oxygen consumption and the action of classical metabolic inhibitors. Homewood and her colleagues (*Proc. helminth. Soc. Wash.*, **39** (special issue), 382; 1972), have utilised a technique based on the observation that the pigment of erythrocytic stages of the rodent malaria parasite *Plasmodium berghei*, clumps when exposed to a low concentration of chloroquine, and that this process is dependent on energy (Warhurst and Robinson, *Trans. R. Soc. trop. Med. Hyg.*, **65**, 11; 1971). From a study of the action of various respiratory inhibitors on pigment clumping induced by chloroquine, Homewood and her colleagues postulated that these parasites possess a very unusual, branched electron transport chain. The major branch, they suggested, terminates in an unidentified acceptor of parasite origin, and they believe that the minor branch passes electrons finally to oxygen by way of a cyanide-sensitive cytochrome oxidase system.

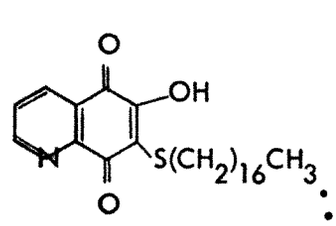
There is now good evidence to show that the erythrocytic stages of a variety of *Plasmodium* species, including *P. berghei*, do indeed contain cytochrome oxidase (mainly in the mitochondria), and that the enzyme occurs also in the mosquito and pre-erythrocytic liver stages (Howells *et al.*, in *Comparative Biochemistry of Parasites*, Academic, London and New York, 1972). The idea that electron transport mechanisms may play a vital part in the malaria parasite has now been exploited by Wan, Porter and Folkers (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 952; 1974) who have synthesised a series of structural analogues of coenzyme Q_8 (I).

During the Second World War antimalarial drug screening



programme Fieser and his associates (*J. Am. chem. Soc.*, **70**, 3151; 1948) synthesised several 2-hydroxy,1,4-naphthoquinones that proved to be highly inhibitory to growth of the duck malaria parasite *P. lophurae* and two of these were eventually tested in man. They produced, however, some side reactions—apparently due to an effect on blood clotting mechanisms—that were, fortunately, antagonised by the administration of vitamin K1 (II). Subsequent investigations

II vitamin K_1



showed that these antimalarials inhibit mammalian and parasite respiration, an effect that could be reversed in the former by the addition, *in vitro*, not of vitamin K1 but of ubiquinone 10 (also referred to as coenzyme Q_{10}, or CoQ_{10}).

It is now known that *P. lophurae* synthesises ubiquinone 8 and 9 (Rietz *et al.*, *Int. Z. VitamForsch.*, **37**, 405; 1967) and that ubiquinone 7 and 8 are synthesised by *P. berghei* and two simian malaria species which do not contain vitamin K_1 (Skelton *et al.*, *J. med. Chem.*, **13**, 602; 1970). These observations have opened a new line of thought as to the mode of action of the napthoquinones, as well as providing a unique target for selective toxicity, since the host tissues of both birds and mammals synthesise a different coenzyme, namely ubiquinone 10. It was soon demonstrated that both the older 2-hydroxy, 1,4-napthoquinones as well as some newer members of the series, including menoctone (III), inhibit DPNH

III menoctone

oxidase and succinoxidase systems *in vitro*, both systems being ones in which CoQ plays an essential part. These observations encouraged the synthesis of further compounds structurally related to ubiquinone 8, the most recent of which are 7-alkylmercapto-6-hydroxy-5,8-quinolinequinones (Wan *et al.*, *loc. cit.*). One of them, the heptadecyl derivative (IV), combines a high level of activity both against the blood stages of *P. berghei* and especially against the tissue stages of the avian parasite *P. gallinaceum* with a very low level of toxicity to the host. There are thus two chemical series, one characterised by menoctone (III) with its 8 carbon alkyl, 3 cyclohexyl sidechain, the other by compound IV with 16+1 carbons in the saturated straight alkyl chain, both of which show a high degree of antimalarial activity and low host toxicity. It seems quite possible that they function as antimetabolites by blocking one or more sites concerned with the biosynthesis of CoQ_8 within the malaria parasite. In the menoctone series activity against *P. berghei* is lost as the chain length is either decreased or increased, both in relation to the blood (Berberian and Slighter, *J. Parasit.*, **54**, 999; 1968) and tissue stages (Berberian *et al.*, *ibid.*, 1181).

IV 7-heptadecylmercapto-6-hydroxy-5,8-quinolinequinone

Menoctone has been shown to cause selective structural damage to the well developed mitochondria of the tissue stages of avian malaria (Beaudoin *et al.*, *Milit. Med.*, **134**, 979; 1969). Although in the blood stages of *P. berghei* the mitchondria appear to be relatively primitive, it now seems clear that they do play an important part in the production of energy through the electron transport chain. It is therefore interesting to note that menoctone also induces ultrastructural changes in these mitochondria (Howells *et al.*, *Ann. trop. Med. Parasit.*, **64**, 203; 1970).

These compounds thus approximate to the definition of the ideal antimalarial which has been stated to be one that would (among other virtues) combine action against all stages of the parasites with minimal toxicity to the host. Although preliminary studies with menoctone against *P. falciparum* in man (*Tech. Rep. Ser. Wld Hlth Org.*, No. 529, 70; 1973) and the 7-octadecylmercapto analogue of IV against *P. cynomolgi* in monkeys (Wan *et. at., loc. cit.*) have been disappointing, the basic experimental data and theoretical considerations indicate that the further exploration of these potential antagonists of CoQ_8 may well provide a rare opportunity for the rational synthesis of an antiparasitic agent with highly selective toxicity, the dream of every experimental chemotherapist since Paul Ehrlich. A word of caution, however, is necessary. The observations of Howells *et al.* (*loc. cit.*; 1970) indicate, perhaps not surprisingly, that the malaria parasite may be equipped already with a means of overcoming such interference with its vital respiratory processes.

W. PETERS

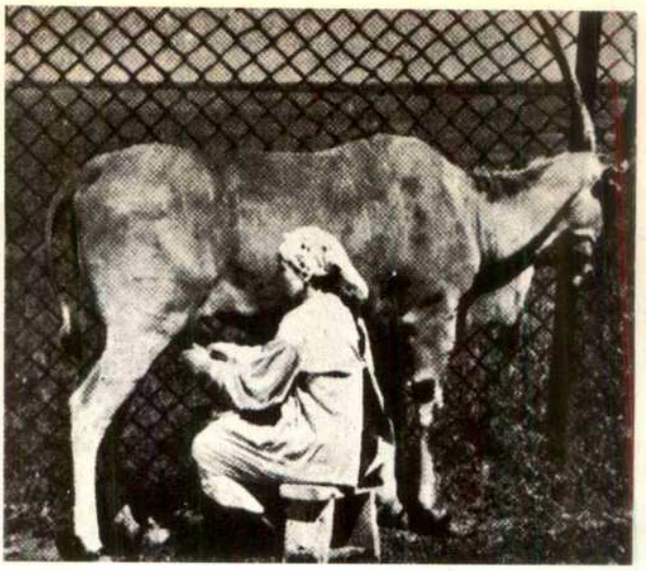
Another bursal equivalent

STUDY of the lymphoid system in birds has revealed a thymus at the anterior and bursa (of Fabricius) at the posterior end. Both organs are thought to play a primary part in the development of the lymphoid system and immunological responsiveness. Stated in its simplest form the notion is that the thymus produces T cells which are responsible for cell-mediated immunity (that is against foreign grafts) and the bursa emits B cells which produce humoral antibody.

Initially it seemed that these two modes of immunity, like the antithetic East and West of Rudyard Kipling, should never meet. In mammals, particularly mice, the thymus is present and it produces T cells and these cells are responsible (at least in part) for cell-mediated immunity. The bursa in mice is less obvious and murine T cells collaborate with murine B cells (B stands for bursal equivalent here) to facilitate the production of antibody by the B cells. All this looks sensible and seems to indicate that birds and mammals differ in their lymphoid systems and manner of immunological responsiveness. (It would be more accurate to say that chickens and mice differ.) But immunologists are spending much time and energy in trying to reconcile these apparent differences, and the definition of a mammalian bursal equivalent in particular has become a sort of crusade. Owen, Cooper and Raff raise the banner once again on page 361 of this issue of *Nature*. Owen *et al.* first assem-

bled a series of fluorescein-conjugated, class specific, anti-mouse immunoglobulin antibodies in order that they could identify B lymphocytes by direct absorption of the fluorescent antibody and subsequent counting of stained cells in an appropriate microscope. They make the assumption that surface immunoglobulin on a morphologically indentifiable lymphocyte is sufficient definition of the cell as a B cell.

These methods were then applied to liver and spleen of foetal mice of various gestational ages. It was found that until 17 days of foetal life, no B (or T) lymphocytes were detectable. They then took 14-day foetal liver and cultured it *in vitro* for up to 7 days. Within 3 days 0.1% of all cells were stained and within 7 days as many as 3%. Over the same time course there was found in the explanted livers an increase in the proportion of small lymphocytes from 0% to 3%. In these circumstances Owen *et al.* very reasonably conclude that B lymphocytes develop in relatively large numbers in foetal liver in tissue culture. They also point out that, whether or not their deduction that the foetal liver is a bursal equivalent proves to be validated, the system of experimentation they have adopted provides an opportunity for the study of the putative class switch in immunoglobulin synthesis, and the generation of antibody diversity in the absence of T cells.



It is being found with increasing frequency that non-lymphoid cells can demonstrate some of the best recognitional characteristics of T and B lymphocytes (see, for example, Elliott, Kerbel and Phillips, *Nature*, **248**, 514; 1974). It is to be hoped that this does not prove true of surface-bound immunoglobulin, because if it did Owen *et al.* would have to show that their fluorescent cells were morphologically small lymphocytes.

A. J. S. Davies

Protein for population

from our Animal Ecology Correspondent

Of the many problems facing policy makers of sub-Saharan Africa today, the increasing protein deficiency for the spiralling human population is about the greatest. It is of historical interest to note that protein production has traditionally rested on the performance of domestic livestock. In some African countries the problem has been tackled by the importation of protein-rich foods. But the high price of these foods renders them unavailable to all but 25% of the population. The other 75% rely on caterpillars, maggots, snails, fish and wildlife for their protein.

African eland being milked at Askanyia Nova in the Crimea, USSR, where there is a domesticated herd. The milk has more fat and protein and less water than that of domestic cattle and is more resistant to some bacteria (from Crawford, *Oryx*, **12**, 321; 1974).

Asibey has pointed out (*Biol. Cons.*, **6**, 32; 1974) that natural meat, or bushmeat as it is called, represents big money. In one market in Accra species such as hare, giant rat, grasscutter, duiker, green monkey and bushbuck fetched US $0.46 per pound. During 18 months the cash turnover from 348,000 pounds (158,000 kg) of meat was US $160,000. If planners need to see the future in terms of money they should take a look at their own back garden. This, above all, may convince them that the true solution rests with the effective and efficient exploitation and management of naturally occurring wildlife.

There are other, more important, reasons why the bushmeat industry should be encouraged and given the protection of careful management. These concern conversion and growth efficiencies of wild game compared with domestic stock. Eland show a liveweight gain of 0.73 pounds (0.33 kg) per day; domestic cattle on reasonably managed rangeland in East Africa gain about 0.3 pounds (0.14 kg) per day. Crawford (*Oryx*, **12**, 351; 1974) uses this example to highlight the need for field studies. When eland and cattle are kept in the same laboratory their conversion efficiencies are similar. But on the arid plains the eland's performance is characterised by lability. By allowing its body temperature to rise with the ambient temperature—and it can even exceed the air temperatures and radiate heat—it has no requirement to sweat or pant. The saving of body water, critical in many parts of Africa, is considerable. Of course it is only able to allow its body temperature to rise because of certain adaptations to its heat balance system. These include a *rete mirabila* overlying the brain which functions as a heat sink. Furthermore, bushmeat species are remarkably resistant to infections that kill domestic stock, and they seldom destroy the phytosociological structure of their habitats.

Both Asibey and Crawford independently make a plea for rational and scientific management of natural stocks. Clearly, if the resource is to withstand fairly heavy exploitation then close scrutiny must be made of population processes in the wild. Crawford sees two possible ways in which management could be directed. One is towards the establishment of monocultures of eland, wildebeest, gazelle or kob. The other is towards polyculture establishment using a range of game animals occupying different feeding niches and maintaining a great complexity and diversity of vegetation. Ecologically speaking the polyculture system is the more viable since overgrazing and overbrowsing are less likely to occur than in monoculture.

With the standing crop of bushmeat being around 70,000–100,000 pounds per square mile (12,000–17,400 kg km^{-2}) and of domestic stock around 11,000–16,000 pounds per square mile (1,900–2,800 kg km^{-2}), it is inconceivable that this valuable resource will have to wait long before heavy exploitation begins. And neither it should, if the people of Africa are to have meat to eat. Asibey's plea for intensive and detailed management studies must not go unheeded by the architects of the new Africa.

African buffalo. (Photo.: M. Crawford). Their long gestation period (compared with domestic cattle) ensures that calves are born in the rainy season.

Galapagos seismic gap filled

from Peter J. Smith
Geomagnetism Correspondent

ALTHOUGH all active oceanic ridges are marked by chains of shallow focus earthquakes, the density of epicentres is far from uniform throughout the ridge system. There are, for example, far fewer events along fast-spreading ridges than along slow-spreading ridges. Macdonald and Mudie (*Geophys. J.*, **36,** 245; 1974) have examined earthquakes of magnitude 5.0+ along spreading ridge sections (that is, excluding those events associated with known transform faults), as recorded during the years 1961-1969 by the World Wide Standardised Seismograph Network (WWSSN), and find that on average there were 8 shocks per 1,000 km of ridge for the northern mid-Atlantic Ridge, where the spreading rate is 12 mm yr^{-1}, but less than one shock per 1,000 km along the East Pacific Rise, where the spreading rate is 35–50 mm yr^{-1}. Moreover, fast-spreading ridges are particularly prone to apparent gaps in seismic activity of up to hundreds of kilometres in length. Along the East Pacific Rise between 36° S and 49° S, for example, there are seismic gaps (as revealed by WWSSN records) as long as 1,400 km.

Another area in which there seems to be a seismic hiatus, according to the WWSSN, is the 600-km long central Galapagos spreading centre, a ridge section spreading at a half-rate of 32.5 mm yr^{-1} between the Cocos plate to the north and the Nazca plate to the south. But is earthquake activity truly absent from this region, or is the gap in seismicity merely a reflection of the low sensitivity of land based stations? To find out, Macdonald and Mudie used sonobuoys in an attempt to detect seismicity at close range along the Galapagos spreading centre—in other words, to see if, notwithstanding the lack of large earthquakes, they could detect microearthquake (magnitude less than 4.0) or earthquake swarm activity. The attempt succeeded. During 45 h of recording time (not continuous) Macdonald and Mudie detected an average of 15 events an hour near the ridge axis and up to 80 shocks an hour at the peak of a swarm which occurred a few kilometres from the ridge. Magnitudes ranged from $m_b = -0.4$ to $m_b = +0.8$. This is the first time that the microseismicity of a fast-spreading ridge with no activity detectable by the WWSSN has been measured.

The association with an active ridge leaves little doubt that the recorded microearthquake activity is caused by seafloor spreading processes, although the specific origin is more difficult to determine. Sykes (*J. geophys. Res.*, **75,** 6598; 1970), who investigated ridge swarms elsewhere recorded by the WWSSN, attributed such swarms to volcanic, hydrothermal or magmatic processes on the ridge crest; and it seems probable that one or more of these processes are also responsible for the Galapagos events. Williams *et al.* (*Eos*, **54,** 244; 1973) suggested that hydrothermal circulation may be an important method of heat transfer at the Galapagos ridge crest, for heat flow there can be greater than 30 heat flux units and narrow, near-bottom, positive water temperature anomalies of several hundredths of a degree have been found over the crest near, as it now turns out, the source of the microearthquake activity. But what is probably the most convincing evidence comes from the Macdonald-Mudie study itself. The b value for the Galapagos events (the frequency-magnitude parameter in the relation $\log N = a - bm_b$, where N is the number of events of magnitude m_b or greater) is very high at 3.0, which is consistent with a volcanic or magmatic source but not with the generally much lower b values for fracture zone events.

Flowing superfluid films

from Peter V. E. McClintock
Condensed Matter Correspondent

THE thickness of a superfluid helium film below 1 K is reduced by an increment which varies quadratically with the velocity at which the film is flowing, according to an experiment by Williams and Packard of the University of California at Berkeley (*Phys. Rev. Lett.*, **32,** 587; 1974).

Some of the most dramatic demonstrations of superfluidity in liquid ^{4}He below its superfluid transition temperature at 2.18 K are found in the remarkable phenomena associated with helium films. Any surface dipping into the liquid rapidly becomes covered with a film whose thickness depends on the nature of the surface, and the height above the 'bulk liquid, but which is usually a few hundred Å.

Up to a certain critical velocity the film encounters no resistance to its motion and, being thus enabled to flow freely at several tens of cm s^{-1}, can act as a channel through which relatively large volumes of the liquid can be transferred: in fact the film can act as a syphon through which a small vessel of helium will empty itself in a matter of minutes, the helium flowing up the inner wall and then down the outside.

The film is held in position by the attractive Van der Waals force between the wall and the helium atoms, and measurements of the thickness of static films are found to be in reasonable agreement with theoretical predictions based on the assumption that the film always adjusts itself so as to minimise its total potential energy in the combined Van der Waals and gravitational potentials.

In the case of a flowing film, however, it may not be possible for the thickness to reach this equilibrium value since the velocity of flow is limited to the critical velocity, above which dissipative processes set in very rapidly. Although the situation is very complicated, Kontorovich was able to show (*Zh. eksp. teor. Fiz.*, **30,** 805; 1956) that, under these conditions, the thickness should be reduced by an amount depending on the square of the flow velocity.

Subsequent experiments above 1 K in a number of laboratories, however, demonstrated conclusively that the thickness was actually independent of the velocity. A possible explanation of this apparent conflict between theory and experiment was given by de Bruyn Ouboter (*J. low Temp. Phys.*, **12,** 3; 1973) who pointed out that Kontorovich's analysis had considered equilibrium conditions only within the film itself and had ignored the influence of the surrounding helium vapour: a flowing film in internal dynamic equilibrium would clearly be in disequilibrium with the vapour which, by condensing, would tend to bring the thickness back to its value for a static film. One obvious experiment to test this hypothesis was to repeat the measurements at temperatures below 1 K where the saturated vapour pressure is so small that condensation on the moving film would be a negligible effect. This is the experiment which has now been carried out by Williams and Packard.

Their experimental cell was cooled by means of a dilution refrigerator to temperatures well below 1 K, and was designed to measure the transfer rate of helium between two reservoirs, while at the same time monitoring the thickness of the flowing film. The latter measurement was performed by making the film flow between a pair of capacitor plates so that a change in its thickness resulted in a small change in their capacitance, which could be measured externally. By this means, changes as small as 2 Å could be detected. By using a second pair of capacitor plates to form the walls of one of the reservoirs, the volume of liquid present could be measured as a function of time, thus enabling the film flow rate to be deduced. The authors found that the film became considerably thinner when flowing, than when it was static. At 0.26 K with a

critical velocity of 28 cm s^{-1} the film thickness was reduced by 56 Å.

By investigating transient effects which occurred as the flow started and stopped, they were able to measure the film thickness for velocities less than the critical velocity and they found that the thinning was proportional to the square of the velocity as had been predicted by Kontorovich.

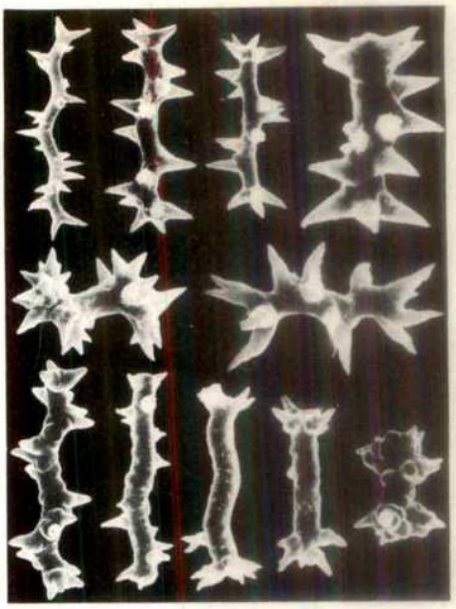
These measurements provide a satisfying demonstration of the general validity of Kontorovich's analysis. They also, however, demonstrate the corrections of de Bruyn Ouboter's suggestion of the importance of vapour condensation for films at temperatures above 1 K, which has implications for a whole range of other experiments and proposed experiments. Williams and Packard point out, in particular, that by providing a dissipative mechanism, such condensation processes may be responsible for the experimental non-appearance of persistent currents in helium films above 1 K. So that this latter hypothesis may be put to the test, it is to be hoped that further experiments seeking persistent currents in helium films will soon be carried out at temperatures well below 1 K, where the influence of the vapour is negligible.

Complexities of the Afar triple junction

from Ian Gass

DURING the past five years the Afar has been the site of intensive investigations by French, German and Italian research teams, as well as by individual scientists from the United Kingdom and United States. A meeting on the Afar region, held at Bad Bergzabern, West Germany, from April 1-6, was anticipated with mixed feelings. Undoubtedly much new information would be available, but would it in any way make the processes at this unique terrestial triple junction any more explicable? These misgivings were unfounded: the symposium was an outstanding success. The lasting impression is of the excellence and abundance of the German geophysical data and of the French and Italian field, structural and petrochemical studies.

The following points were repeatedly emphasised; that (1) the continental crust beneath Afar has been markedly attenuated; (2) the underlying upper mantle is anomalous to depths of 300 km with maximum recorded P wave velocities in the range 7.3–7.4 km s^{-1}; (3) movement, both vertical and horizontal, volcanic activity and deformation are episodic with periods of activity interspersed with intervals of quiescence; (4) the major volcanic activity commenced some 34 Myr ago and that older dates on trap basalts are open to considerable doubt; (5) the disposition of volcanic rock types is far more complex than originally thought; (6) the precise demarcation line between the Nubian, Somali and Arabian plates can be identified more closely than before within the Afar depression but that its position on or around the Danakil Alps is still a matter of personal prejudice.



Both R. Black (University of Montpellier) and W. H. Morton (University of Addis Ababa) convincingly demonstrated that crustal attenuation had taken place by a process of rotating fault blocks. Morton proposed that the angle of faulting was a direct reflection of the degree of attenuation in the upper brittle crust while the lower crust deformed plastically. The German seismic data, reported by H. Berckhemer (University of Frankfurt), and the gravity information (J. Makris *et al.*, University of Hamburg) proposed anomalous mantle under Afar though that below the highland is normal. The gravity model presented showed a mantle of 3.15 g cm^{-3} within 20 km of the surface and thinnest beneath the rift zones; a space form similar to that proposed by Gass in 1969 on petrological criteria is indicated. Magnetotelluric measurements (A. Berktold, University of Munich), deep electrical conductivity (H. Porath *et al.*, University of Dallas) and surface wave dispersion (R. C. Searle, National Institute of Oceanographic Sciences, Wormley) all support the presence of low density mantle at high level beneath Afar. Farther to the south a similar space form was proposed for the Kenya rift by R. E. Long (University of Durham), J. D. Fairhead (University of Leeds) and N. Logatchev (Institute of the Earth's Crust, Irkutsk) on teleseismic, gravity and petrological data respectively, although the depth to anomalous mantle varies somewhat.

Time and time again speakers emphasised the periodicity of activity. H. Faure (Centre National de la Recherche Scientifique, Bellevue) demonstrated spasmodic vertical uplift in the order of 0.3 mm yr^{-1} around the Gulf of Tadjura. F. Berberi *et al.* (University of Pisa) and J. Varet (University of Paris) also emphasised the spasmodic nature of uplift which they dated as occurring mainly between 45-40, 25-20 and 5-2 Myr with volcanic maxima between. Although the generally spasmodic nature of events was acknowledged, the longest pause—that proposed by R. W. Girdler and P. Styles (University of Newcastle-upon-Tyne) for a cessation of spreading in the Red Sea between 34-5 Myr—was questioned. Many found it difficult to accept that all was quiet in the Red Sea while volcanism, uplift, crustal attenuation and deformation were going on all around.

Petrologically the picture has altered from the symplistic views of the late 1960s and this is mainly due to the recognition of tholeiitic basalts within the Ethiopian Trap series as well as within the depression. Although generations of basaltic liquids within an area of high heat flow (the use of the term mantle plume being deliberately avoided) is generally accepted, it is quite apparent that factors other than depth of equilibration are relevant and more correlated field, age, petrographic and geochemical data are required before a realistic petrogenetic model can be erected.

Lastly, and perhaps appropriately, the position of the dividing line between the three plates, although becoming more precisely defined, is still masked by the

Inside a sponge

To anybody whose familiarity with sponges goes no further than the bathroom, it may come as a surprise that the bath sponge *Euspongia* is just one of many examples of the sponge phylum Porifera. The strange-looking structures in the figure shown here make up the skeleton of another form of sponge, *Cliona dioryssa*, which burrows into calcareous rocks. This species is one of eight burrowing sponges which Dr Klaud Rützler has been studying in Bermuda (*Smithson. Contrib. Zool.*, No. 165; 1974). Although *Cliona* is sufficiently similar to *Euspongia* for both to be included in the same broad class, the Desmospongia, the skeletons are different; *Cliona*'s skeleton is made up of the siliceous spicules shown here whereas that of *Euspongia* is composed of a horny substance called spongin.

complexity of surface deformation and the super-abundance of Recent volcanic products. Over large areas it is, within limits, a matter of choice as to where it is put—and that alone will keep the arguments going.

Support for deep mantle convection

from Peter J. Smith
Geomagnetism Correspondent

ASSUMING that the engine driving the Earth's lithospheric plates involves some sort of convection in the mantle, do the convection cells reach down to the core-mantle boundary or are they relatively shallow? Views on this point have changed significantly since the idea of motions in the mantle was first proposed. Put briefly and simply, convection as originally envisaged was regarded as mantle wide, with the currents moving the passive lithosphere by viscous coupling. As the new global tectonics developed during the 1960s, however, the nature of the asthenosphere became clearer and the lithospheric plates themselves came to be seen as possible driving forces (acting under gravity, for example). The result was that convection cells became conceptually shallower, being limited to the upper mantle or even to the lithosphere–asthenosphere. More recently, sporadic attempts have been made to reverse this trend by reviving mantle-wide convection but have generally received little support. The latest such attempt is by Robinson (*Earth planet. Sci. Lett.*, **21**, 190; 1974) who has managed to refute the two serious criticisms of mantle-wide convection put forward some years ago by Ringwood (*ibid.*, **14**, 233; 1972).

Robinson's two-dimensional model involves steady cellular convection driven by heat from below. The cells are 3,000 km deep (the thickness of the mantle) and 1,400 km wide (which is within observed trench-ridge separations), but their most important characteristic is that their limbs are narrow. In other words, the convection of heat between the core-mantle boundary and the Earth's surface layer takes place within a narrow (100–200 km) boundary layer, the vertical segments of which form narrow ascending and descending 'plumes'. This immediately avoids Ringwood's first problem, which is that the necessary 200° C mean temperature difference between the ascending and descending currents in the conventional wide-limbed mantle-wide convection model would imply gravity anomalies at the Earth's surface more than 100 times greater than those observed. In Robinson's model the corresponding temperature difference is of the order of 1,000° C but is confined to the narrow plumes. The resulting gravity anomalies are thus comparable to those actually observed.

The second problem that Ringwood pointed to was that of "re-establishing a superadiabatic gradient by thermal conduction after completion of half a turn of the cycle", the point being that superadiabatic gradients are necessary to drive the convection currents. According to Ringwood, the time required for conduction through 3,000 km of mantle would be 2.5×10^{10} yr, so that "only one convective overturn could have occurred throughout the history of the Earth". But according to Robinson, this problem does not arise in his model because the time scale for conduction through a narrow boundary layer is much shorter than that of the convective cycle. In any case, the superadiabatic gradient in the plumes (the temperature gradient inside the cells is adiabatic) could be maintained by energy stored in the core. Ringwood rejected this notion on the grounds that unacceptable radioactive abundances would be required in the core, and that even if the necessary deep heat could be found it would lead to unacceptably high surface heat flow. Robinson argues, however, that the narrow plumes of his model avoid the need for high surface heat flow and that one can envisage heat sources in the core which do not involve radioactivity.

Advances in lichenology

from a Correspondent

PROGRESS and problems in lichenology were considered at a meeting at the University of Bristol on April 8-10. It was the first international symposium held in Britain devoted solely to lichens and was organised jointly by the Systematics Association and the British Lichen Society.

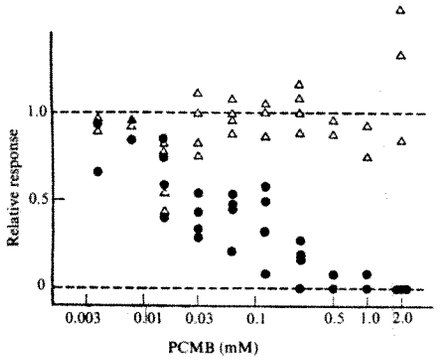
Some fundamental questions as to the nature of lichens were raised by P. W. James (British Museum (Natural History)) and A. Henssen (Botanical Institute, Marburg) who reported convincing evidence that a single fungal partner with different types of algae (green and blue green) can produce morphologically very different individuals traditionally placed in different genera. The production of some chemical components used in lichen taxonomy may also be affected by the algae present. The use of chemical characters in lichen taxonomy was reviewed by D. L. Hawksworth (Commonwealth Mycological Institute, Kew) who suggested guidelines for the taxonomic treatment of chemical races in lichens, and R. W. A. Oliver (University of Salford) demonstrated the value of mass spectrometry and high pressure liquid chromatography for the accurat determination of substances in smal amounts of herbarium specimens Lichen taxonomy is also being clarifie by studies of ontogeny (Henssen algal components (E. Tschermak Woess, Botanical Institute, Vienna and by scanning electron microscop (M. E. Hale, Smithsonian Institution

On the ecological side F. Ros (King's College, London) showed th value of lichens as indicators of ancien woodlands in relatively unpollute parts of Britain, M. R. D. Seawar (Trinity and All Saints' Colleges, Leeds reported on the performance o *Lecanora muralis* in urban areas an A. Fletcher (University College o North Wales, Anglesey) described th ecophysiology of marine and maritim lichens. Distributional studies on world scale (P. W. James) and i Britain (B. J. Coppins, Royal Botani Garden, Edinburgh) were also reported A novel technique for measurin lichen growth rates was proposed b R. A. Armstrong (University o Oxford) and R. H. Bailey (Departmen of Extra-Mural Studies, London pointed to gaps in knowledge of th establishment and dispersal of lichens

Physiological studies formed the basi of several contributions. Sulphur up take and metabolism using radio actively-labelled sulphur — subject relevant to the use of lichens as ai pollution indicators—were reported b B. W. Ferry (Bedford College, Lon don) and the uptake of heavy metal in lichens was discussed by D. H Brown (University of Bristol). Nitroge fixation and transfer in lichens con tinue to provide an interesting field fo research as was shown by J. W. Mill bank (Imperial College, London). Th physiology of symbiosis itself and th transfer of carbohydrates were dis cussed by J. F. Farrar (Imperial Colleg Field Station, Silwood Park) and D. J Hill (University of Newcastle upo Tyne).

D. C. Smith (University of Oxford compared the lichen symbiosis wit other symbiotic systems; he pointe to many similarities and stresse that from the laboratory stand point lichens were ideal organisms i which to study symbiosis itself. Th concept of controlled parasitism of th algal partner by the fungus may, how ever, be preferable to one of symbiosi in lichens.

In conclusion R. Santesson (Univer sity of Stockholm) pointed to the re surgence of interest in lichens and th stimulus which this meeting provide for further work. It is clear that lichen ology is a field in which many prob lems, both old and new, require fur ther research, but also one in which i is still relatively easy to make import ant original contributions.



Sugar receptor sites in the fly's tongue

from our
Insect Physiology Correspondent

SINCE the isolation of a 'sweet-sensitive protein' from the bovine tongue there has been increasing interest in the properties of sensory receptor substances and receptor sites. Von Frisch studying the honeybee in 1935 and Dethier studying the blowfly in 1955 failed to discover configurations that were common to the stimulating carbohydrates and were absent in the tasteless ones. But their results underlined the extreme specificity of insect receptors as compared with those of mammals. Dethier observed, however, that the weakly stimulating sugar, mannose, markedly reduced stimulation by fructose but had no effect on glucose sensitivity. Evans (1961) inferred that there must be at least two different sites in the sugar receptor of the blowfly tongue, a 'glucose site' and a 'fructose site'.

Shimada *et al.* (*J. Insect Physiol.*, **20**, 605; 1974) have now re-investigated this problem in the large labellar hairs of the flesh fly *Boettcherisca peregrina*. In earlier work these authors had found that the sugar receptor in this fly with respect to sucrose could be modified by treatment with the sulphhydryl reagent, *p*-chloromercuribenzoate (PCMB). PCMB seemed to react with sulphhydryl groups in proteins of the sugar receptor, but not at the sugar-binding site; it apparently blocked a change in the permeability of the receptor membrane. Shimada *et al.* have now made a detailed study of the effects of PCMB on the electrophysiological response of single receptor hairs, to fructose, glucose and other sugars.

It turned out that there is a striking difference in the effect on the response to glucose and fructose: response to glucose was completely repressed; response to fructose was unaffected (see figure). This constitutes the first direct demonstration of the existence of a 'glucose site' and a 'fructose site' as suggested since Dethier (1955). When a range of other monosaccharides was tested it was found that these fell into two groups: D-fructose, D-fucose, and D-galactose react chiefly with the 'fructose site'; D-arabinose, L-fucose, L-arabinose, L-sorbose, D-xylose, L-glucose and D-glucose mostly with the 'glucose site'. In the disaccharides sucrose and maltose the glucose moiety predominates and both react with the 'glucose site'. High concentrations of glucose exert no specific protective effect against PCMB treatment: this supports the view that PCMB may not react at the glucose-binding site but at a different site necessary for stimulation by D-glucose.

Depression of responses to fructose and to glucose by treatment with *p*-chloromercuribenzoate at graded concentrations. Ordinate: response relative to that before treatment. Duration of treatment with PCBM was always 3 min. △, 0.1M fructose; ●, 0.2M glucose.

From a discussion of these results and the known equilibrium changes in the conformations of a single sugar in aqueous solution, Shimada *et al.* adopt the more precise terms 'pyranose site' and 'furanose site' (instead of 'glucose site' and 'fructose site') representing the sites which respond especially to sugars in the pyranose and furanose forms respectively. The pyranose group was further divided into two subclasses according to the presence or absence of three successive equatorial hydroxyl groups regardless of their positions.

Positive control in the test tube

from Benjamin Lewin
Molecular Genetics Correspondent

TURNING on gene expression *in vitro* has in general proved to be more difficult than switching it off, for although several systems have been developed in which specific repression takes place in the test tube, characterisation of positive control systems has been less successful. The positive control system investigated in most detail to date is the catabolite activator protein stimulated by cyclic AMP, whose mediation is necessary for expression of several inducible and repressible operons. Although this system seems to act on the initiation of transcription, little is known about the molecular details of its activity. Several papers in the March issue of the *Proceedings of the National Academy of Sciences* now take the analysis of positive control *in vitro* a stage further in three systems.

The first positive control system to be suggested was that of the arabinose operon, in which genetic analysis implied that a repressor protein might be converted by arabinose into an inducer protein (instead of simply suffering the inactivation characteristic of negative control systems). Lee *et al.* now report (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 634; 1974) the development of a system in which the regulator protein, activated by arabinose, and the catabolite activator protein, stimulated by cyclic AMP, are both needed for initiation of transcription. Using a template of phage λ carrying the arabinose genes, synthesis of *ara* messenger RNA can be followed by hybridisation first with λ DNA (to remove phage sequences) and then with λ *ara* DNA. This system seems completely dependent on the catabolite activator protein, is stimulated by the arabinose regulator protein in the presence of arabinose, and is inhibited by fucose (an anti-inducer of the operon). These results support previous suggestions that both the regulator protein and the catabolite activator protein must join with RNA polymerase to initiate transcription. Further analysis of this system may be important in helping to define how regulator proteins may interact with each other and with DNA.

Phage lambda itself provides a system under both negative control (lambda repressor prevents expression of integrated lysogenic lambda genomes) and positive control (needed both for the establishment of lysogeny and also for lytic development). Establishment of lysogeny depends on two phage functions (*cII* and *cIII*) in addition to the repressor coded by the *cI* gene, and also upon host genes. One of the host functions has now been identified by Belfort and Wulff (*ibid.*, 779), who have isolated *hfl*⁻ mutants of *Escherichia coli* that show very high frequencies of lysogenisation after lambda infection. Because the *hfl*⁻ mutation is recessive, it is likely that it is caused by the loss of an active *hfl*⁺ gene product, which usually prevents establishment of lysogeny. Because λ phage DNA lacking an active *cIII* gene continues to achieve the same high frequency of lysogenisation in *hfl*⁻ cells that is displayed by wild type λ, it is possible that the *hfl*⁺ function is usually antagonised by the *cIII*⁺ gene product.

That the host catabolite activator system also is implicated in establishment of lysogeny is suggested by the reduction in lysogenisation frequency in mutants defective in this system. Belfort and Wulff found that whereas these host mutants display a slight reduction in frequency of lysogenisation by λ⁺ phages, they show a massive reduction in lysogenisation by *cIII*⁻ mutants. That the catabolite activator and *hfl* systems both act in the same pathway as the *cIII* phage gene product is shown by the observation that the inability of catabolite activator host mutants to lysogenise λ *cIII*⁻ mutants is reversed by the introduction of an *hfl*⁻ mutation. Because catabolite re-

pression is normal in *hfl*⁻ strains, it is possible to exclude the idea that this gene specifies a component of the catabolite repression system. The roles of the catabolite activator protein and the *hfl* gene product in establishing lysogeny are not clear, but it is likely that these systems may be more intricate than previously suspected, and further components may remain to be identified.

A different form of positive control, so far demonstrated only with the mRNAs of phages T3 and T7, is exercised by processing systems. The RNA polymerase enzyme of the host, *E. coli*, transcribes one large messenger *in vitro* from the early region of these phages (corresponding to 20% of the DNA, located at its left end). But infected cells contain five, much smaller, early T7 messengers. Recently it has seemed likely that the discrepancy is due to the presence in the cell of an enzyme, RNase III, which cleaves the large precursor RNA (that is the product *in vitro*) into mature messengers. Hercules *et al.* (*ibid.*, 840) now report that this cleavage represents a step essential for phage gene expression, since only the mature mRNAs and not their large precursor, are active as templates for translation *in vitro*. This concept is supported by the observation that the early phage genes are only poorly translated in RNase III⁻ mutants of *E. coli*. Why the precursor RNA cannot be translated is obscure; but this system may well prove interesting from the viewpoint of translational control as well as for its processing mechanisms. And although no bacterial systems have yet been shown to suffer precursor maturation as a prerequisite for translation, it is an interesting possibility that RNase III may play this part in uninfected bacteria.

Turning to the transcription of T3 and T7 DNAs which takes place by the phage specified polymerase later during infection, Golomb and Chamberlin (*ibid.*, 769) have mapped the principal units of gene expression. With a template of T7 DNA, the T7 RNA polymerase forms six size classes of mRNA (molecular weights 5.5, 4.5, 2.0, 0.8, 0.4 and 0.2×10^6) equimolar in proportion except for the 2×10^6 species which seems to comprise two classes of mRNA. When the T7 DNA template is shortened by the removal of regions from its right end with nucleases, the smallest mRNA is no longer produced, and the mRNAs of 5.5, 4.5 and (one of) 2.0×10^6 daltons are shortened. Since all these messengers are complementary only to the r-strand of T7 DNA and can be synthesised in spite of deletions at the left end, it seems likely that they are derived from overlapping units of transcription; transcription may start at promotor sites located at 56, 64 and 83% along the phage DNA from its left end, and may end at a common termination site near the right end of the molecule.

When T3 DNA is used as a template for the T7 RNA polymerase, a single major RNA species is formed of 2.0×10^6 daltons. Hybrids between T3 and T7 DNA show various patterns of transcription, consistent with an overlapping arrangement of transcription units. Since hybrid templates can be examined by heteroduplex mapping to define precisely which regions are derived from T3 and which from T7, future use of this technique may allow the start and stop points of the polymerase to be mapped more precisely. There are two classes of late gene in T7, and so it is tempting to speculate that they may be represented by the two classes of mRNA, one comprising the overlapping transcription units and the other corresponding to the remaining messengers. Although previous suggestions have quite often been made that transcription might start at one point and end at any one of several sites to allow coordinate or noncoordinate expression of adjacent genes, the late phage overlapping messengers seem to achieve the same end by reversing the roles of the start and stop points. It remains to be seen whether this has wider significance for the uninfected bacterium.

How algae survive desiccation

from Peter D. Moore
Plant Ecology Correspondent

FEW habitats are subjected to the extremes of environmental conditions experienced by the intertidal zones of coasts. Plants and animals living in these regions face wide fluctuation in temperature, insolation, salinity and desiccation with each ebb and flow of the tide. Most of these organisms are essentially marine and therefore it is the period of emersion which represents the stress phase which must be tolerated to ensure survival. The effect of this stress is not laid evenly over the eulittoral zone, but is most acute at its higher levels, where the emersion period is most protracted. It is this variation of stress intensity with vertical height which, in conjunction with the factor of interspecific competition, accounts for the well known intertidal zonation of benthic marine algae (see Zaneveld, *Am. Zool.*, **9**, 367; 1969).

Many of the algae of the upper eulittoral suffer emersion periods of several days, sometimes even weeks, during which they become thoroughly desiccated. The physiological mechanisms which enable these morphologically simple plants to survive such stresses have been a source of interest to botanists for some while.

One aspect of algal physiology which has received attention is that of carbon balance, especially during emersion periods. Chapman (*Proc. 5th Int. Seaweed Symp. Halifax N.S.*, 217; 1966) found that the respiration rate of *Carpophyllum* decreases as desiccation proceeds, falling to 20% of the hydrated rate at 80% desiccation. Bidwell and Craigie (*Can. J. Bot.*, **41**, 179; 1963) also demonstrated that carbon fixation is reduced during emersion in *Fucus vesiculosus*. Ogata (*J. Shimonosaki Univ. Fish.*, **16**, 89; 1968) has since reported that the depression of respiration rate during desiccation is found in many algae, but that rehydration results in an almost instantaneous resumption of normal respiration.

The current *Carnegie Institution of Washington Year Book*, which covers the years 1972–73, contains information concerning the effect of desiccation on the photochemical reaction of photosynthesis in an intertidal alga. Fork and Hiyama (page 384) have made a study of *Porphyra perforata* and *P. tenera*, species of the upper eulittoral zone. Under normal, hydrated conditions cytochrome *f* is oxidised by light and becomes reduced in darkness. This ceased to happen if the plants had been dried in the sun, which could mean that no electrons were available from the oxidation of water, or possibly that there was a physical uncoupling of cytochrome *f*. Rewetting of the alga immediately resulted in light induced oxidation of cytochrome *f*, indicating that the primary photochemical apparatus had survived the drying process.

The stability of the photosynthetic equipment of *Porphyra* comes as no surprise to botanists who are familiar with this upper shore alga which daily suffers desiccation yet survives. This work does, however, demonstrate most precisely the nature of this stability. This plant's resilience is even more remarkable when one considers its apparently delicate structure; unlike the robust fucoids, *Porphyra* forms sheets of tissue just one cell in thickness. For this very reason *Porphyra* may prove to be an eminently suitable subject for future studies on subcellular responses to extreme environmental conditions.

Correction

IN the News and Views article "Palindromes in eukaryotic DNA" (*Nature*, **248**, 733; 1974), the sequence in the third paragraph should read:

5′ .... A B C *t* C′B′A′ .... 3′
3′ .... A′B′C′ *t* C B A .... 5′

and not as printed.

Two plates in Africa during the Cretaceous?

Kevine Burk & John F. Dewey
Department of Geological Sciences, State University of New York at Albany, Albany, New York 12222

Plate tectonic theory is based on the idea of the conservation of displacement at the ends of major faults[1]: ridges, trenches and triple junctions are linked by transform faults so that a plate boundary may not end except by joining two others at a triple junction. This is a consequence of the motion of torsionally rigid plates in which large permanent strains are restricted to narrow boundary zones. Although brittle intraplate deformation occurs[2], excellent fits between rifted continental margins[3] and between pairs of magnetic anomaly isochrons[4] show that plates do not generally suffer significant torsional strains.

Provided that the zones in which large, permanent deformations occur are narrow relative to the plates they surround, plate tectonics is a useful theory. The behaviour of wide zones of interplate deformation may be approximated either by 'soft' regions such as the Himalayas and Tibet[5] or by complex microplate systems such as the present Mediterranean[6].

It is important to understand to what extent relative plate displacements can be registered as strain in a zone too wide and diffuse to be realistically termed a plate boundary. We describe here a wide zone of strain that developed in Africa during the Cretaceous, recognition of which leads us to the view that Africa, from about 125 Myr ago to about 80 Myr ago, was not behaving as a single rigid plate.

Evolution of the Benue Trough

PLATE accretion began in the South Atlantic about 125 Myr ago, during the late Valanginian–early Hauterivian[7]. Aptian rock salt and carnallite in the Gabon Basin overlie a mainly non-marine sequence and are themselves overlain by marine shales and carbonates (Fig. 1). This provides evidence of a narrow proto-South Atlantic with restricted circulation during late Aptian times[8]. Plate accretion and separation of South America from Africa followed an early Cretaceous phase of intracontinental rifting and magmatism. During this phase rifts were formed, along which plate accretion subsequently occurred. Rifts, some of which contain up to 9 km of sediment, were generated striking at high angles to the continental margin[9]. In Africa and South America, nodal alkaline and peralkaline magmatism and widespread basaltic and rhyolitic volcanism occurred during this rifting phase. The rifting and magmatic activity have been related to the development of domes, crested by rift systems with three branches, which occur at hot spots[10]. Plate accretion began on two rift arms, leaving the third as a failed arm or aulacogen[11].

The Benue Trough (Fig. 2) is one such rift but it differs from others in that plate accretion occurred along it during early Cretaceous times. Three pairs of magnetic anomalies strike north-eastward beneath the Niger Delta[12,13]; we suggest that they are late Keathley sequence anomalies developed in Hauterivian–Barremian time during the early opening of the Benue Trough, when a ridge–ridge–ridge triple junction existed in the proto-Gulf of Guinea. The oldest sediments exposed in the Benue Trough are Albian shales (Fig. 1) which pass up into a sequence of Albian to early Santonian shales with minor Turonian alkali basalts and thick Cenomanian deltaic sequences (Fig. 1). We suggest that this mainly sedimentary sequence was deposited in an already open, or slowly opening, narrow ocean. Near the top of the sequence, late Coniacian andesites are intercalated in shales. The whole sequence was folded during the Santonian (Fig. 1) about axes which strike north–east[14]. We interpret the late Coniacian andesites as evidence of subduction of part of the oceanic floor of the Benue Trough, and the Santonian folds as indicating closure of the trough. We are unsure of relative motion, if any, across the Benue Trough during Albian to Turonian times, though the Turonian alkali basalts may indicate very slow extension[15]. Twice, therefore, during the Cretaceous evolution of Africa, a plate margin passed into the continent from a triple junction in the Gulf of Guinea, so that there must have been two African plates at these times, one south-east and one north-east of the Benue Trough. To where did these plate margins continue in Africa, and how and over what area was relative displacement between the two African plates expressed as strain?

Cretaceous Africa north-east of Benue Trough

There is no evidence of a discrete well-defined plate margin north-east of the Benue Trough during either the Hauterivian–Barremian extensional phase or the Coniacian–Santonian convergent phase. We will discuss the extensional phase first and then the convergent phase.

Extensional phase. The Benue Trough divides at the Chum and Poli triple junctions to form three rifts[16], one of which, the Poli, continues as a subsurface feature marked by a positive Bouguer anomaly (Fig. 2). Louis[17] modelled this gravity

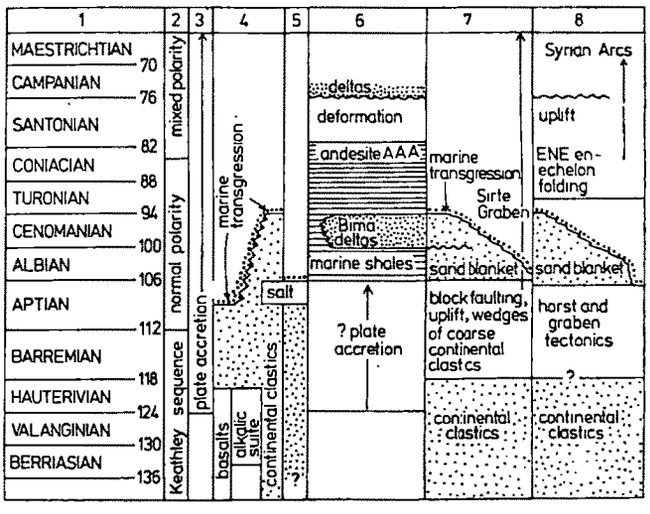


Fig. 1 Correlation chart showing relationships between magmatism, tectonics and sedimentation during the Cretaceous in northern and western Africa and eastern South America. 1, Cretaceous stages; 2, geomagnetic behaviour; 3, plate accretion in South Atlantic (ref. 7); 4, development of eastern continental margin of South America (based mainly on refs 37–39); 5, Gabon Basin (ref. 8); 6, Benue trough (refs 12–15); 7, Algerian and Libyan Sahara (refs 22–26); 8, Egypt and Levant (refs 24, 27). Note that Early Cretaceous magmatism largely predates the development of accreting plate margins and the associated distension of northern Africa.

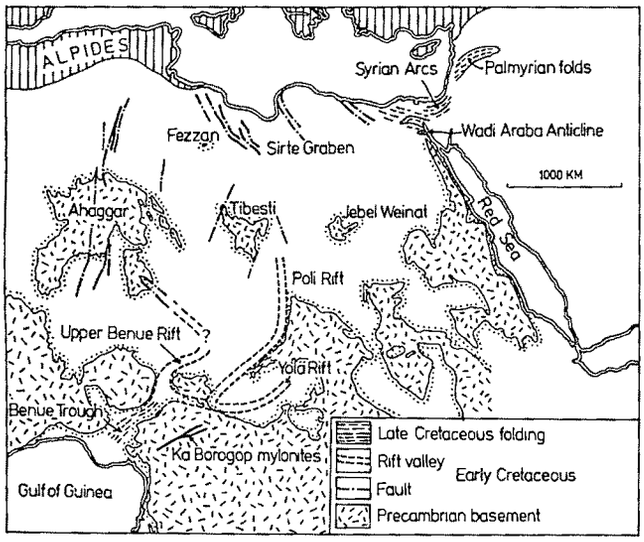

Fig. 2 Northern part of the African continent showing Early Cretaceous rifting and distensional structures and Late Cretaceous folding and compressional structures (based mainly on refs 36, 28 and 17).

anomaly as a basaltic dyke up to 30 km wide. Burke and Whiteman[16] interpreted it as one of the axial dykes related to extension, which are becoming widely known in rift valleys[18-21]. The Upper Benue and Yola intracontinental rifts contain Cenomanian continental sandstones equivalent to the Bima deltas of the Benue Trough that prograded south-westwards along the narrow Benue Ocean. From the Berriasian until the Hauterivian, most of North Africa was covered by a thin veneer of continental deposits. During the Barremian–Aptian, block faulting and differential regional uplift affected a wide region of North Africa from the Algerian Sahara to Egypt[22] (Figs 1, 2 and 3*B*). Most of the block faulting took place on reactivated basement faults trending roughly north-south. Tibesti was uplifted and shed sand wedges[23], and north–south block faulting in the Ahaggar was accompanied by local spreads of coarse clastics in graben, and erosion or nondeposition over horsts[24]. The Jebel Weinat Massif was also rising at this time[25]. In north-west Libya, gentle folding of early Cretaceous rocks occurred before the deposition of late Aptian sediments[26] and, in the Fezzan, Cenomanian sediments rest unconformably on older Cretaceous rocks. These strong differential movements over the Algerian Sahara and Libya, ceased by Albian times. An Albian sandstone sheet of fairly uniform thickness completely covers the Barremian–Aptian structures[24]. The Sirte graben complex of northern Libya (Fig. 2) controlled sedimentation during the middle and late Cretaceous. In Egypt, faults trending north–west were active during Barremain–Aptian times, producing a series of graben and horsts with up to 2 km of shale. The Barremian–Aptian activity suggests that a large region of northern Africa (Fig. 2) was slowly distending, between two African plates, in response to the same displacement that was being accommodated by plate accretion in the Benue Trough.

Compressional phase. The Cretaceous deformation of the Benue Valley is dated as Santonian (Fig. 1). Deformation was also occurring elsewhere in northern Africa at this time[24]. The Syrian Arcs, the Wadi Araba anticline and related structures (Fig. 2) began to form late in the Turonian and grew during the Coniacian and Santonian (Fig. 1). An important sub-Campanian unconformity records this deformation phase in Egypt (Fig. 1). In the Levant, the Santonian rests directly on gently folded Turonian and older rocks[27]. The Ka Borogop mylonite belt (Fig. 2) is not Precambrian, as was previously thought, but affects Cretaceous conglomerates[28]. Its upper age limit is unknown but we here suggest that it was developed, during the Coniacian–Santonian closing of the Benue Trough, perhaps with a significant strike-slip component (compare with ref. 29). Therefore, although convergence of the two African plates was accommodated by subduction in the Benue Trough it was apparently taken up by intracontinental compression over at least part of the region of northern African affected by Barremian–Aptian distension. Although the relative displacement of the two plates may not have been large we are unable to determine its magnitude or precise direction. The Benue Trough was a structure which narrowed towards the continent during the early Cretaceous and all early Cretaceous strain between the Benue Trough and Egypt seems to have been extensional. This suggests that the pole of relative motion between the two African plates at this time lay north-east of Egypt. In plate tectonic terms, the broad zone of extension may be regarded as either a plate boundary up to 2,000 km wide or as a series of smaller intracontinental plates. If nothing were known of the history of the Benue Trough this extensional zone might be regarded as an enigmatic zone of intraplate, intracontinental rifting.

Stresses unrelated to latitudinal motion

Intraplate earthquakes, well away from possible plate boundary effects, yield dominantly thrust fault and strike-slip first motion solutions on all present major plates, indicating that plates are undergoing local, brittle deformation in response to compressive stresses[2]. There is no clear pattern of compression directions, but compression has been deduced at localities from latitudes of about 60°N to 40°S. Intraplate extension has been deduced only for eastern Baffin Island and southern Africa.

We have argued[10] that intraplate extension which yields intracontinental rift-valley systems is related to the growth of hot spot domes and periclines. As the domes grow, they are characterised by alkaline and peralkaline magmatism and eventually by crestal rifting, commonly in three-armed systems. This hot spot phase of intracontinental rifting and magmatism may be protracted and abortive but it may lead to a phase in which rift valleys propagate and link up, followed by continental fragmentation and the opening of oceans by plate accretion[30]. Burke and Wilson[31] have argued that extensive hot spot activity before continental separation may indicate

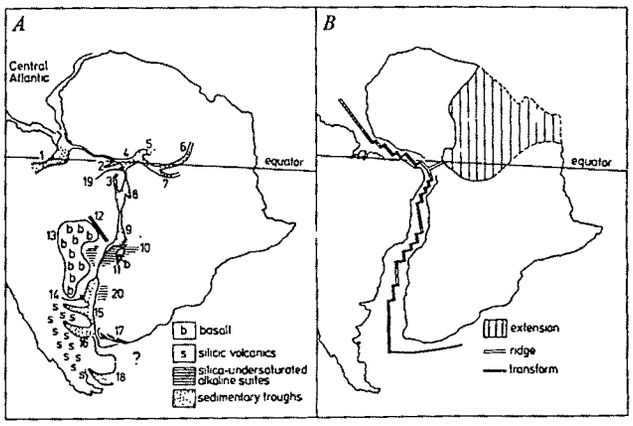

Fig. 3 *A*: Berriasian–Valanginian magmatism, tectonics and sedimentation on the site of the future South Atlantic. 1, Marajo basin (ref. 37); 2, Potiguar basin (ref. 37); 3, Jucano basin (ref. 37); 4, Benue trough (ref. 12); 5, Upper Benue rift (ref. 16); 6, Poli rift (ref. 17); 7, Yola rift (ref. 16); 8, Sergipe-Gabon basin (ref. 39); 9, Cuanza basin (ref. 40); 10, Angola alkaline province (ref. 41); 11, Kaokoveld basalts (ref. 42); 12, Goiana arch (refs 37 and 38); 13, Parana basalts (ref. 37); 14, Pelotas basin (ref. 37); 15, Rio Salado basin (ref. 9); 16, Bahia Blanca basin (ref. 9); 17, Algoa and associated Cape Province basins (ref. 43); 18, Malvinas basin (ref. 9); 19, Cabo granite and associated silicic alkaline rocks (ref. 37); 20, Messum alkaline province (ref. 44). *B*: Aptian plate boundaries in the South Atlantic and Africa. The circle with a dot lies in the general area of a pole describing the Aptian motion of north-western Africa with respect to south-eastern Africa.

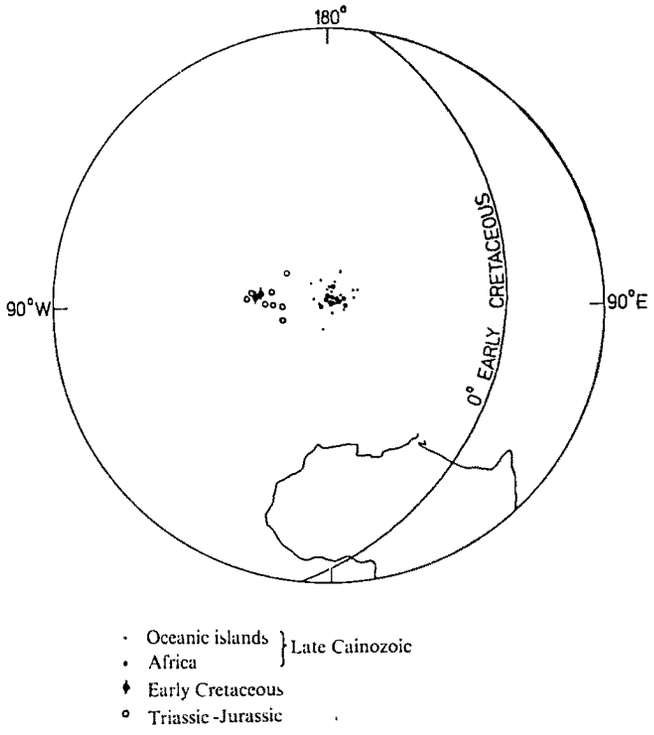

Fig. 4 Palaeomagnetic poles for the African plate (refs 33 and 34) form two groups marking times in the Mesozoic and Tertiary when the plate was at rest with respect to the spin axis. Between about 100 and 25 Myr ago African plate motion with respect to the main dipole field was approximately a 30° rotation about a pole in the Gulf of Guinea. Rifting and igneous activity dominated the continent while it was at rest and were minimal while it was moving.

that the continent, or plate, in question was stationary or moving very slowly with respect to underlying mantle plumes. Once plate accretion between two continental fragments begins, hot spot activity may diminish or cease on one or both of the fragments; if motion relative to the plume population is fast. Our model of rift valley generation involves a hot spot phase with dominantly vertical movements and only mild extension, followed by a phase of extension leading to continental break up.

Turcotte and Oxburgh[32], using membrane stress theory, have adopted a different view of intraplate deformation. They argue that as plates, considered as thin elastic membranes, change their radius of curvature as they change latitude, stresses build up. If, for instance, a portion of a plate were moving to a lower latitude at a rate of 1 cm yr^{-1}, then membrane stresses would equal the tensile strength of the lithosphere after 30 Myr, provided that the stresses were not dissipated. An increase in latitude of 90° would, however, be required before membrane stresses were about equal to the compressive strength of the lithosphere. Membrane stresses thus cannot account for the widespread intraplate compressive failure of the lithosphere[2] although they could, theoretically, generate tensional failure to form rift valleys. If intracontinental extension and rifting results from the propagation of cracks developed in response to membrane stresses, extension should predate magmatism. In rift valleys generated by hot spots, magmatism should predate significant extension. We here show that the early Cretaceous tectonic–magmatic history leading to the separation of Africa and South America and the opening of the Benue Trough favours the hot spot interpretation.

From about 160 to 120 Myr ago, magmatism was widespread in the general region along which Africa separated from South America (Fig. 3*A*). Alkaline and peralkaline igneous rocks were intruded and extruded in distinct nodes (Cabo Granite, Rio de Janeiro, Messum); basalts (Parana, Kaokoveld) and rhyolites (southern Argentina) formed extensive volcanic provinces. During and after this magmatic phase, great thicknesses of non-marine Valanginian to Barremian sediments accumulated in troughs with faulted boundaries (rifts and aulacogens) parallel and at high angles to the future continental margins of South America and Africa. The beginning of plate accretion in the South Atlantic overlapped the waning phases of magmatism and aulacogen formation (Fig. 1) yet nonmarine sedimentation persisted until middle to late Aptian times. The sea had invaded the Benue Trough by earliest Albian times and it is likely that the Benue Trough opened during the extension of North Africa (Figs. 1 and 3*B*). Significant extension leading to the separation of South America and Africa, the opening of the Benue Trough and the distension of North Africa, postdated most of the early Cretaceous magmatic–aulacogen phase.

Late Triassic to early Cretaceous palaeomagnetic poles for Africa[33] cluster closely around a mean at 265°E, 65°N (Fig. 4). While Gondwana was breaking up there were no systematic changes to lower latitudes of the kind needed for an explanation in terms of membrane stress of the associated early Mesozoic rift systems. Africa, during approximately the last 25 Myr of its history, has been characterised by a similar episode of hot spot uplift, volcanism and rifting. African palaeomagnetic poles for this time interval[33,34] similarly cluster around a mean near the present pole (Fig. 4). Rifting and magmatism in Africa have developed at times when Africa did not change its latitude. Between 110 and 25 Myr ago Africa changed its position, relative to the spin axis, in a way that may be approximated by an anticlockwise finite difference rotation of 30° around a pole at 0°N, 10°W (Fig. 4). During this time there was little or no rifting or magmatism on the African continent.

The closing of the Benue Trough and the compression of North Africa occurred at a time of major changes in relative plate motion. As a result of the opening of the Labrador Sea, the relative motion of Africa with respect to Europe changed to an anticlockwise rotation about a pole at 25.4°N, 163.8°E (ref. 35). Plates moving with respect to underlying plumes may generally be in compression whereas those that are at rest with respect to underlying plumes develop tensional features related to hot spot activity.

Repeating sequences in aminoacyl-tRNA synthetases

G.L.E. Koch, Y. Boulanger* & B.S. Hartley

Medical Research Council, Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH

Some aminoacyl-tRNA synthetases have elongated by fusing two very similar sequences.

AMINOACYL-tRNA synthetases are responsible for the specificity of translation of the genetic code. They each catalyse a similar reaction in which a particular amino acid reacts with ATP probably forming a 5′-aminoacyl adenylate, which then transfers to the 3′-terminal adenosine of a particular tRNA, eliminating AMP. Their specificities are also similar in that different tRNAs have similar structures[1] and that each enzyme requires an unsubstituted α-amino acid and ATP for the complete reaction.

To avoid errors in protein synthesis, however, they must be completely specific for a particular amino acid and a particular tRNA. Since the genetic code seems to be universal, this specificity has been conserved over a very long period. We might therefore expect these enzymes to be a family with homologous primary and tertiary structures that are under enormous selective pressure to conserve their essential features.

The accumulation of data on the protomeric units of several synthetases has revealed an objection to this view, however. Broadly, four classes of synthetases can be defined on the basis of protomer size and binding capacity. (1) Those containing a single polypeptide chain with a molecular weight of about 120,000 and containing one binding site for amino acid and tRNA, for example, isoleucyl-tRNA synthetase from *Escherichia coli*[2,3]. (2) Those containing two identical protomers each with a molecular weight of about 90,000 and possessing one binding site for amino acid and tRNA per protomer, for example methionyl-tRNA synthetase from *E. coli* (ref. 4, and G.K., unpublished). (3) Those containing two identical protomers each with a molecular weight of about 40,000, for example, tryptophanyl-tRNA synthetase from *E. coli*[5]. (4) Those containing dissimilar protomers, for example phenylalanyl-tRNA from yeast[6], glycyl-tRNA synthetase from *E. coli*[7]. This wide diversity in the sizes and organisation of the protomers does not seem consistent with the concept of evolution from a common precursor since the known classes of homologous protein generally contain protomers of very similar size. These apparent inconsistencies have led us to isolate several aminoacyl-tRNA synthetases from a single source, the thermophile *Bacillus stearothermophilus*, and to search for sequence homologies between them.

Enzymes from *B. stearothermophilis*

Aminoacyl-tRNA synthetases are present in low amounts in most cells and many of them are denatured during the lengthy purification that is necessary. The thermophilic organism, *B. stearothermophilus* was chosen as a source because proteins from this species exhibit remarkable stability. A purification procedure that yields about 100 mg of pure leucyl-, methionyl-, tryptophanyl-, tyrosyl- and valyl-tRNA synthetases from 5 kg wet weight of these cells has been developed in collaboration with the Microbiological Research Establishment, Porton Down, Wilts. All enzyme samples used in these studies were more than 95% pure.

Before determining any of the chemical parameters of these enzymes their subunit structures had to be established. The molecular weights of the native proteins determined by gel filtration[8] were usually sufficiently accurate (Table 1). On the other hand, it was essential to estimate the sizes of the protomers on proteins which had been completely de-

*Present address: Université Louis Pasteur, Laboratoire de Biochemie, Rue R. Descartes, 67 Strasbourg, France

Table 1 Subunit structures of *B. stearothermophilus* synthetases

Aminoacyl-tRNA synthetase	Molecular weight (native)	Molecular weight (subunit)	Subunit structure
Tryptophanyl-	70,000 (E, F)	35,000 (S, G)	2 × 35,000
Tyrosyl-	95,000 (F)	44,000 (S)	2 × 44,000
Methionyl-	135,000 (E, F)	66,000 (S, G)	2 × 66,000
Valyl-	100,000 (F)	110,000 (S, A)	1 × 110,000
Leucyl-	100,000 (E)	110,000 (S, A)	1 × 110,000

natured and dissociated. For this purpose the proteins were either boiled in 1% SDS or preoxidised with performic acid and boiled in 1% SDS. The molecular weights of the protomers were determined by electrophoresis in SDS-polyacrylamide gels[9] or by gel filtration on columns of SDS-agarose (Table 1). Investigations of the tryptophanyl-enzyme were hampered by autolysis in the stored preparations. The size of the protomers in methionyl-tRNA synthetase was confirmed by equilibrium ultracentrifugation in the presence of 6 M guanidine hydrochloride[10]. The results show that valyl- and leucyl-tRNA synthetase are monomeric proteins

Table 2 Amino acid compositions of *B. stearothermophilus* synthetases

Amino acid	Aminoacyl-tRNA synthetase Tyrosyl-	Methionyl-	Valyl-	Leucyl-

* Calculated on the basis of the molecular weights of the protomers.
†From analyses of the oxidised protein, using oxidised chymotrypsinogen as standard. This procedure can give over estimates of up to 15% for cysteic acid.
‡ Estimated by the method of Edelhoch[17].

with molecular weights of about 110,000 whilst tyrosyl- and methionyl-tRNA synthetase are dimers whose protomeric units have molecular weights of 45,000 and 66,000 respectively.

To facilitate the discussion the amino acid compositions of the proteins shown in Table 2 have been calculated on the basis of the molecular weight of the protomers present in each protein. Since the cysteine (cysteic acid) contents of the enzymes proved small, special precautions were taken to ensure the accuracy of its analyses. Hydrolysates of chymotrypsinogen and *B. amyloliquefaciens* RNase[11] (which contains no cysteine) were used for calibration and the values shown are the averages of several analyses.

Repeating sequences

The first indication that some of the protomers might contain repeating sequences was found in maps of the tryptic peptides but the most convincing evidence for their existence came from estimates of the molar yields of several tryptic peptides from each of the proteins. It was assumed that yields greater than 1 mol of peptide per mol protomer would prove the existence of at least two copies of the corresponding sequence in the intact protomer. Since the approach relies on the isolation of pure peptides in high yield, certain precautions had to be taken. Preliminary experiments had shown that trypsin digestion was more complete when the proteins were denatured by oxidation rather than carboxymethylation. The trypsin was purified on trypsin inhibitor-Sepharose columns in order to minimise nontryptic cleavages in the digest, and wherever possible only those peptides which were pure after a single purification step were considered since we could not correct for losses during purification.

The tryptic digest of oxidised methionyl-tRNA synthetase was fractionated by ion-exchange chromatography on Locarte L1/5 resin using a gradient of pyridinium-acetate for elution[12]. This procedure (Fig. 1) resolved several peptides which proved pure by paper electrophoresis, paper chromatography and amino acid analysis. The amino acid analyses also gave their compositions and yields. The molar yield of each peptide calculated from them was then used to determine the mol peptide per mol of protomer (Table 3). A similar experiment was performed with tryptic digests of oxidised leucyl-tRNA synthetase using a combination of SP-Sephadex chromotography and Sephadex G-50 gel filtration to purify the peptides. This procedure was preferred to the one used with methionyl-tRNA synthetase because it selectively purified the larger acidic peptides in high yield (Table 3).

The yields of tryptic peptides from valyl-tRNA synthetase were estimated by a different procedure. The protein was carboxymethylated with ^{14}C-iodoacetate[13], digested with trypsin and the radioactive peptides purified by paper electrophoresis and chromatography. By using radioactive peptides losses during purification could be corrected. Note that the yields (Table 3) have been calculated from the amino acid analyses of the purified peptides and not from the yield of radioactivity which is an unreliable criterion. Nevertheless, the radioactive label was useful in enabling corrections for losses to be made at each step in purification.

The results show that the protomers of methionyl-, valyl- and leucyl-tRNA synthetase gave several peptides with yields between one and two per protomer (Table 3).

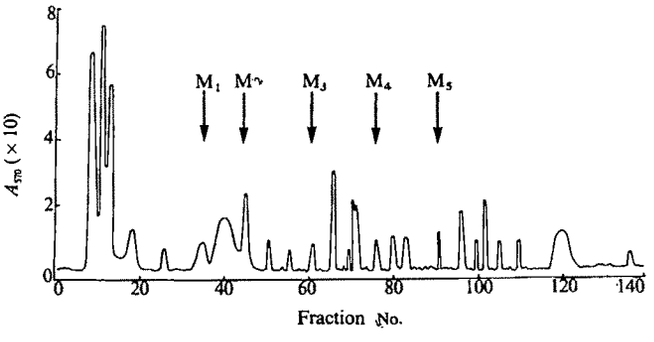

Fig. 1 Separation of the tryptic peptides from methionyl-tRNA synthetase. Enzyme (26 mg) was oxidised with performic acid, digested with trypsin (1:100, w/w) for 4 h at 37° C in 0.5% NH_4HCO_3 and lyophilised. The peptides were dissolved in 0.2 M pyridine–acetate *p*H 3.1 and applied to a column (1 cm × 60 cm) of Locarte L1/5 resin equilibrated with the same buffer. The peptides were eluted with a gradient of pyridine–acetate

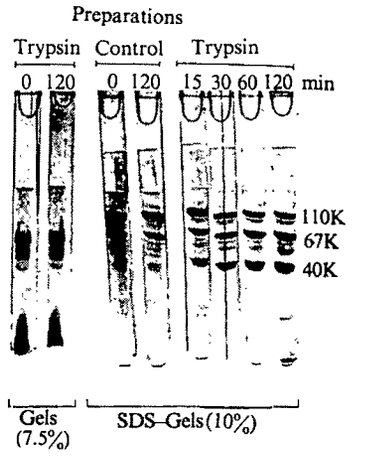
$$\frac{175 \text{ ml}\quad 0.2 \text{ M pyridine–acetate } pH\ 3.1}{350 \text{ ml}\quad 2 \text{ M pyridine–acetate } pH\ 5.0}$$

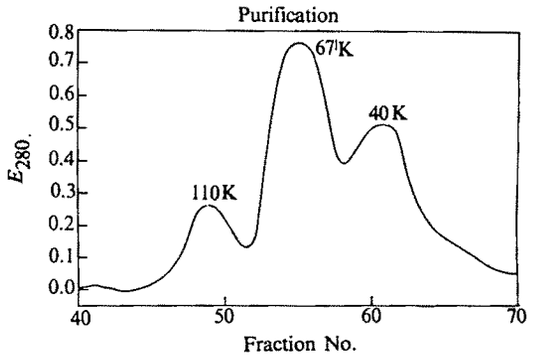
One-sixth of the effluent was monitored automatically for peptides by the ninhydrin reaction after alkaline hydrolysis, and the rest collected in fractions which were pooled on the basis of the elution profile. Each subfraction was tested for homogeneity by paper electrophoresis at *p*H 6.5 and 2.1. The material from each of the arrowed peaks contained only one peptide.

The relatively low yields for the peptides from methionyl-tRNA synthetase are probably a result of losses during purification. All the same, the yields provide strong evidence for more than one copy of each of those peptides in the protomer.

Distribution of repeated sequences



The distribution of the repeated sequences might indicate how the proteins have evolved, but would seem to need knowledge of the entire primary structures. We have attempted a short cut which relies on splitting each protomer into a few large fragments and then surveying the fragments for certain peptides. If a peptide is contained within more than one large fragment then the repeating units which make up the protomer are large. If it is contained within one fragment, then the repeated regions must be relatively short and close to one another.



This approach has proved to be useful with valyl-tRNA synthetase. The native enzyme consists of a single polypeptide chain of about 1,000 residues and is extremely sensitive to trypsin which splits the chain into two fragments of unequal size (Fig. 2). The electrophoretic behaviour of the split protein is identical to that of the native enzyme showing that degradation is not extensive. The larger fragment,

The peptides from methionyl-tRNA synthetase were purified according to the procedure shown in Fig. 1. The peptides from leucyl-tRNA synthetase were isolated from a tryptic digest of the oxidised enzyme by passage of the digest through columns of SP-Sephadex C25 equilibrated with 0.17 M pryidine-acetate *p*H 4.7 and Sephadex G50 equilibrated with 1% pyridine. The peptides from valyl-tRNA synthetase were isolated from a tryptic digest of the ^{14}C-carboxymethylated protein. The digest was subjected to paper electrophoresis at *p*H 6.5 and *p*H 2.1 (see Fig. 2), which completely separated the radioactive carboxymethylcysteine peptides. The peptides were eluted with 1 M ammonia and purified to homogeneity by paper chromatography. The pure peptides were then analysed after hydrolysis and the yield of each calculated. The yield was corrected for losses during purification by comparing the amount of radioactivity in each pure peptide with that present in the same peptide in the unfractionated digest. The single letter notation used for amino acids is that proposed in ref. 18.

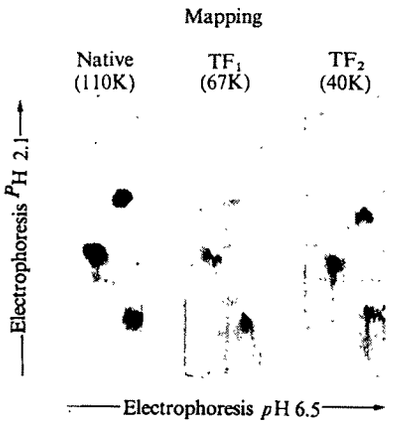

Fig. 2 The distribution of the carboxymethylcysteine sequences between the fragments of valyl-tRNA synthetase. Enzyme (40 mg in 20 ml of 0.1 M Tris-HCl *p*H 7.5) was incubated with trypsin (1:2500 w/w) at 37° C for 2 h. Aliquots were removed at various intervals and subjected to polyacrylamide gel electrophoresis in the presence and absence of SDS. During incubation the native enzyme was split into two fragments with molecular weights of about 67,000 and 40,000. The digested enzyme was made 2% in SDS and 2% in 2-mercaptoethanol, immersed in boiling water for 5 min and passed through a column of agarose 1.5 M equilibrated with 100 mM Tris-HCl, 0.1% SDS and 10 mM 2-mercaptoethanol. Material from the 67K and 40K peaks was pooled and recycled to yield homogeneous preparations. Samples of the native enzyme, valyl-TF_1 (67K) and valyl-TF_2 (40K) were reduced and carboxymethylated with ^{14}C-iodoacetate in 6 M guanidine hydrochloride, digested with trypsin (1:100 w/w) in 0.5% NH_4HCO_3 for 4 h at 37° C and the soluble peptides subjected to two-dimensional mapping by paper electrophoresis. The regions of the maps containing the major radioactive peptides from each sample are shown. The apparent inhomogeneity of the sample is due to considerable overloading of the gels.

valyl-TF_1 (molecular weight 67,000), and the smaller, valyl-TF_2 (molecular weight 40,000), were dissociated and separated from one another by gel filtration on columns of agarose 1.5 M equilibrated with 0.1% SDS. The amino acid analyses show eight half cystines in the native protomer, four half cystines in the large fragment and three half cystines in the small fragment[14]. The three proteins were reduced, ^{14}C-carboxymethylated, digested with trypsin and subjected to two dimensional mapping. Autoradiographs of the maps were prepared to identify the carboxymethylcysteine peptides (Fig. 2). The same radioactive peptides stand out in all three maps showing that both fragments contain the same carboxymethylcysteine sequences. This means that the repeated peptides are distributed between widely separated regions of the protomer and that it is made up of long repeating units and not short, clustered repeats.

When digested with low concentrations of subtilisin, methionyl-tRNA synthetase is converted into a fully active fragment which is composed of a single polypeptide chain with a molecular weight of about 55,000. Methionine is the amino terminus of both the native enzyme and the fragment, indicating that the trypsin digestion has removed a segment of about 100 residues from the C-terminus of the native protomer. The differences between the amino acid analyses of the native enzyme and the fragment show that the excised region contains five lysine and 11 arginine residues and should therefore yield 17 tryptic peptides. Except for the relative intensities of some of the spots, however, two-dimensional maps of the tryptic peptides from the two proteins display almost complete homology (Fig. 3). Such a result would be expected if the native protomer were composed of two long homologous sequences fused end to end, digestion of the excised region from the C-terminus having removed one copy of the duplicated peptides and left the qualitative features of the fingerprint unchanged.

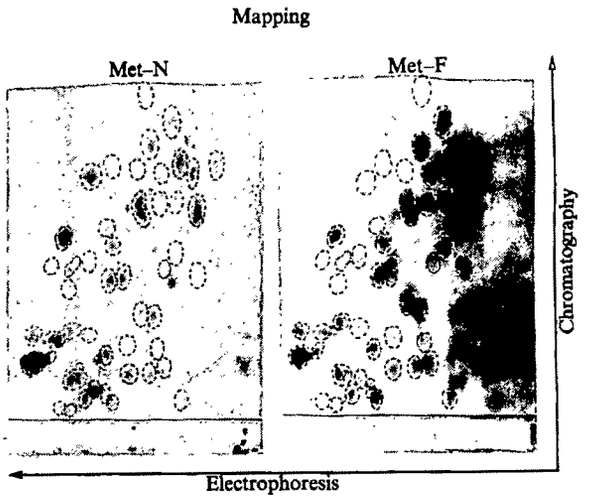

Fig. 3 Two-dimensional maps of the tryptic peptides from methionyl-tRNA synthetase and its subtilisin fragment. The fragment was prepared from the native enzyme by digestion with subtilisin (1:2500 w/w) in 100 mM Tris-HCl *p*H 7.5, and purified by gel filtration on Sephadex G150. Samples of the homogeneous fragment and the native enzyme were oxidised with performic acid, digested with trypsin (see legend to Fig. 1) and the soluble tryptic peptides (over 95% of the proteins used) subjected to paper electrophoresis (formic acid–acetic acid buffer *p*H 2) and paper chromatography (butanol–acetic acid–water–pyridine 30:6:24:20). Maps were stained with 1% ninhydrin in acetone.

Homology of the repeated sequences

To find the degree of homology of the repeating units and the proportion of each protomer made up by the repeating sequences, we tried to determine the number of peptides obtained upon trypsin digestion of each protein by high resolution mapping. Once again oxidised proteins were used since they did not give significant amounts of insoluble material after digestion with trypsin, making nearly all of the protein amenable to mapping.

The tryptic digests of the proteins were first fractionated by ion-exchange chromatography on a column of Locarte L1/5 resin. The peptides were eluted with a linear *p*H gradient, the effluent monitored automatically by the ninhydrin reaction and fractions collected. The fractions containing the material in each of the ninhydrin-positive peaks were pooled, concentrated and each peak subjected to two-dimensional mapping by paper electophoresis at *p*H 6.5 and 2.0. The results obtained with methionyl-, valyl- and leucyl-tRNA synthetase showed that this procedure fractionates the peptides in the digests very well and that the chance of low estimates of the number of tryptic peptides as a result of coincidence is negligible. Table 4 summarises the estimates of the number of tryptic peptides from each protein. Table 4 also shows estimates of the number of arginine and histidine peptides which were determined from two-dimensional maps of the tryptic peptides using the specific stains for these residues. Estimates of the number of cysteine peptides were obtained from studies on tryptic digests of the ^{14}C-carboxymethylated proteins. The number of carboxymethylcysteine peptides among the soluble proteins was determined after fractionation by ion-exchange chromatography followed by paper electrophoresis of the radioactive fractions (Fig. 4). Two radioactive peaks were obtained from methionyl- and leucyl-tRNA synthetase and electrophoresis showed that each contained a single radioactive peptide. Paper electrophoresis of the single radioactive peak obtained from valyl-tRNA synthetase showed two radioactive peptides of equal intensity. The recovery of radioactivity after ion-exchange chromatography exceeded 70% of that applied to the column which excludes the possibility of significant losses of radioactive peptides during

Table 4 Estimates of the number of tryptic peptides

Aminoacyl-tRNA synthetase	Total peptides		Arginine peptides		Histidine peptides		Cysteine peptides	
	Expected*	Observed	Expected*	Observed	Expected*	Observed	Expected*	Observed
Tyrosyl-	56	45-50	28	22	9	10	2	2
Methionyl-	80	40-45	34	19	12	6	5	3
Valyl-	138	50-55	69	32	31	12	8	3
Leucyl-	113	40-45	47	24	26	10	6	2-3

* Calculated from the amino acid analyses shown in Table 2.

The total number of tryptic peptides obtained from each protein was determined from digests of the oxidised proteins. The soluble peptides, comprising over 90% of the protein used for each digest, were first fractionated according to the procedure described in Fig. 1. The material in each peak was then subjected to two-dimensional mapping on paper, the peptides stained with ninhydrin and the number obtained from all the maps used to estimate the total number of tryptic peptides present in the digest. The number of arginine and histidine peptides was estimated by staining two dimensional maps on paper with *o*-phenanthroline and diazotised sulphanilic acid respectively. Estimates of the number of cysteine-containing peptides were determined from tryptic digests of the ^{14}C-carboxymethyl proteins (see Fig. 4).

fractionation. The insoluble peptides from methionyl-, valyl-, and leucyl-tRNA synthetase contained 35%, 20% and 5% of the total radioactivity in the carboxymethylated proteins, respectively. They were solubilised by digestion with thermolysin and subjected to paper electrophoresis. A single radioactive peptide was obtained from each of the insoluble fractions and comparisons with thermolysin digests of the soluble peptides indicated that they were unique. It was concluded that there are no more than three cysteine sequences in each protein of which only two of the three from leucyl-tRNA synthetase can be treated as major peptides. The minor peptide from leucyl-tRNA synthetase is

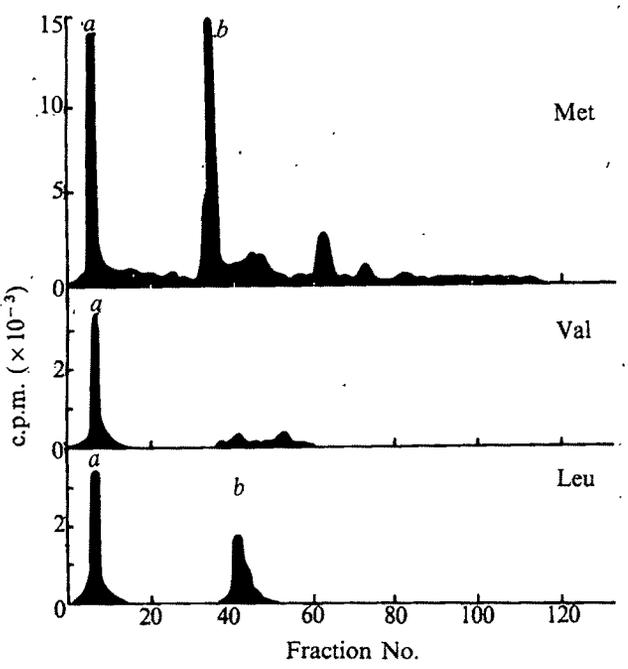

Fig. 4 Estimation of the number of cysteine peptides in tryptic digests of the enzymes. The proteins were reduced and ^{14}C-carboxymethylated in 6 M guanidine hydrochloride, digested with trypsin and the soluble peptides subjected to ion-exchange chromatography under the conditions described in Fig. 1. Aliquots of each fraction obtained from the column were counted for radioactivity and two-dimensional mapping showed that the major radioactive peaks from methionyl- and leucyl-tRNA synthetase contained one radioactive tryptic peptide each, whereas the major peak from valyl-tRNA synthetase contained two radioactive tryptic peptides.

probably a noncysteine peptide which was labelled by the rather drastic conditions used to ensure complete labelling.

It is clear from Table 4 that methionyl,- valyl- and leucyl-tRNA synthetase yield substantially fewer tryptic peptides than the expected number. In all cases the observed number is half, or less than half, the expected number. It is particularly significant that this applies to the histidine and (CM) cysteine peptides since the numbers concerned are quite small. These data, although of a negative nature, strongly suggest that the duplicated regions of these protomers are very similar.

Three lines of evidence

Our conclusion that the protomers of methionyl-, valyl- and leucyl-tRNA synthetase from *B. stearothermophilus* contain repeated sequences is based on three lines of evidence. First, each protomer contained more than one copy of several tryptic peptides. Second, widely separated regions of the protomers contained the same tryptic peptides. Third, all three protomers yield far fewer tryptic peptides than expected if they contained unique sequences over their entire lengths. Taken together, the data also suggest that the repeating units are about half the length of the protomers and that the units within each protomer are very similar in sequence.

These models are unusual since they suggest that in each case two very similar sequences have become fused to yield the functional protomer. Proteins can acquire such repeats by incorporating partial or complete duplications of their cistrons and some proteins have evidently elongated by this process, for example, immunoglobulins[15].

In most of the known cases, however, the sequences of the repeating units have subsequently diverged to an extent substantially beyond that envisaged for the aminoacyl-tRNA synthases which seem to resemble the haptoglobin α_2 chain which is also composed of two virtually identical sequences fused through gene duplication and fusion[16]. It is therefore plausible that the same mechanism has generated the elongated protomers present in some aminoacyl-tRNA synthetases although the possibility of post-transcriptional or post-translational fusion cannot be excluded.

The existence of long duplicated sequences in several of the aminoacyl-tRNA synthetases raises the possibility that other proteins, especially those with relatively long protomers, have elongated in this manner. In fact, there is evidence which suggests that rabbit muscle phosphofructokinase may be one such protein[17].

In none of these cases, however, is the functional advantage of such structures obvious and other information such as the folding of the 'intra-units' and the distribution of active sites between them will probably be necessary to clarify this question. One consequence of the existence of these structures, however, is that it disposes of the objection that the protomers of the aminoacyl-tRNA synthetases differ too much in size to have evolved from a common precursor, since the basic units of sequence are of comparable length although the physical lengths of the protomers are different.

We thank Dr M. F. Perutz for advice on the preparation of the manuscript. Y.B. was the recipient of a travelling fellowship from the European Molecular Biology Organisation.

SUMMARY. A method for association of proteoliposomes with planar phospholipid membrane has been elaborated, by which operation of molecular electric generators, such as cytochrome oxidase, H^+-ATPase and bacteriorhodopsin, can be followed using ordinary electrometer techniques.

THE existence of molecular electric generators in mitochondrial, chloroplast and bacterial membranes was postulated by Mitchell in 1966 who proposed that enzymes of respiratory and photosynthetic redox chains and ATPases localised in these membranes catalyse transmembraneous movement of electrons or protons against the electric gradient. As a result, the membranes should charge like a condenser and electrical energy accumulated in this way might be utilised for ATP synthesis or osmotic work.

This hypothesis is difficult to verify by direct methods because of the small size of intracellular organelles and bacterial cells and the complexity of the enzymic and ion transport processes occurring in these systems. To detect the electric membrane potential in organelles and bacteria, therefore, some indirect methods were developed, such as measurement of electrophoretic transport of penetrating ions, and the electrochromic shifts of carotenoid and chlorophyll spectra[2-8]. In this laboratory, the direct measurement of electromotive force (e.m.f.), produced by one of the molecular electric generators, (bacteriorhodopsin) has been accomplished[9]. *Halobacterium halobium* membrane sheets containing bacteriorhodopsin as the only protein were mixed with a decane solution of phospholipids. The mixture was used to form a planar artificial membrane onto the aperture in the Teflon septum separating two electrolyte solutions. Illumination of the bacteriorhodopsin-containing membrane was found to induce generation of a transmembrane electric potential difference which was measured by a sensitive voltmeter. All attempts to use the same procedure for making planar phospholipid membrane containing cytochrome oxidase and mitocondrial proton-translocating ATPase (H^+-ATPase) failed, however.

Direct measurement

Further experiments yielded a more universal method of direct measurement of the generation of an electric charge by membraneous proteins. The principle of this method is that, firstly, the protein is incorporated into the liposome membrane according to procedure of Racker and associates[10-12] which includes mixing cholate solution of a phospholipid and protein and removal of cholate by means of dialysis. Then, the resulting proteoliposomes are brought into contact with the planar phospholipid membrane. To induce fusion of the planar and proteoliposomal membranes, the negative surface charges of phospholipids are neutralised by Ca^{2+} ions. As voltmeter measurements showed, cytochrome oxidase, H^+-ATPase and bacteriorhodopsin, integrated with planar membrane in such a fashion, can generate a transmembrane electric potential difference at the expense of ascorbate – O_2 electron transfer, ATP hydrolysis and light energy, respectively.

Cytochrome oxidase was purified after the method of Yonetani[13] coupling factor F^1 after Horstman and Racker[14], ATPase hydrophobic proteins after Kagawa and Racker[10], and bacteriorhopsin membrane sheets after Oesterhelt and Stoeckenius[15]. For the procedure of the cytochrome oxidase and ATPase proteoliposome preparations, see ref. 16; for bacteriorhodopsin proteoliposomes, see ref. 17.

Electric potential difference across the planar membrane was measured with Ag/AgCl electrodes connected with the RFT VA J-51 vibrating capacitor electrometer and KSP-4 recorder. Planar phospholipid membrane was made of soya bean phospholipids (azolectin) solution in decane (70 mg azolectin per ml decane). The azolectin solution was applied to a 1 mm aperture in the Teflon septum which separated the experimental vessel into two compartments containing incubation mixture. After the planar membrane was formed, proteoliposomes were added into one of the compartments. In the 15-30 min required for the proteolipsomes to become associated with the planar membrane, an energy source was introduced and the membrane potential was measured.

Proteoliposome systems

The data of a typical experiment with cytochrome oxidase proteoliposomes are given in Fig. 1. As shown in Fig. 1*a*, ascorbate addition to the compartment, containing cytochrome oxidase proteoliposomes and cytochrome *c*, results in the formation of an electric potential difference across the planar membrane (plus in the compartment with proteoliposomes). Cyanide reverses the effect when added after ascorbate. In the experiment shown in Fig. 1*b*, ascorbate (– cytochrome *o*) and proteoliposomes were added to the two different compartments. In this case, no membrane potential was formed until the mixture was supplemented with a penetrating hydrogen atom carrier, phenazine methosulphate (PMS). Direction of the field was the same as in the preceding experiment. An electric potential of opposite polarity (minus on the proteoliposome side) was generated when cytochrome oxidase proteoliposomes containing cytochrome *c* inside were used. Again, PMS was found to be necessary (not shown in Fig. 1).

In Fig. 1*c* the result of the experiment with ATPase proteoliposomes is demonstrated. The addition of ATP to the com-

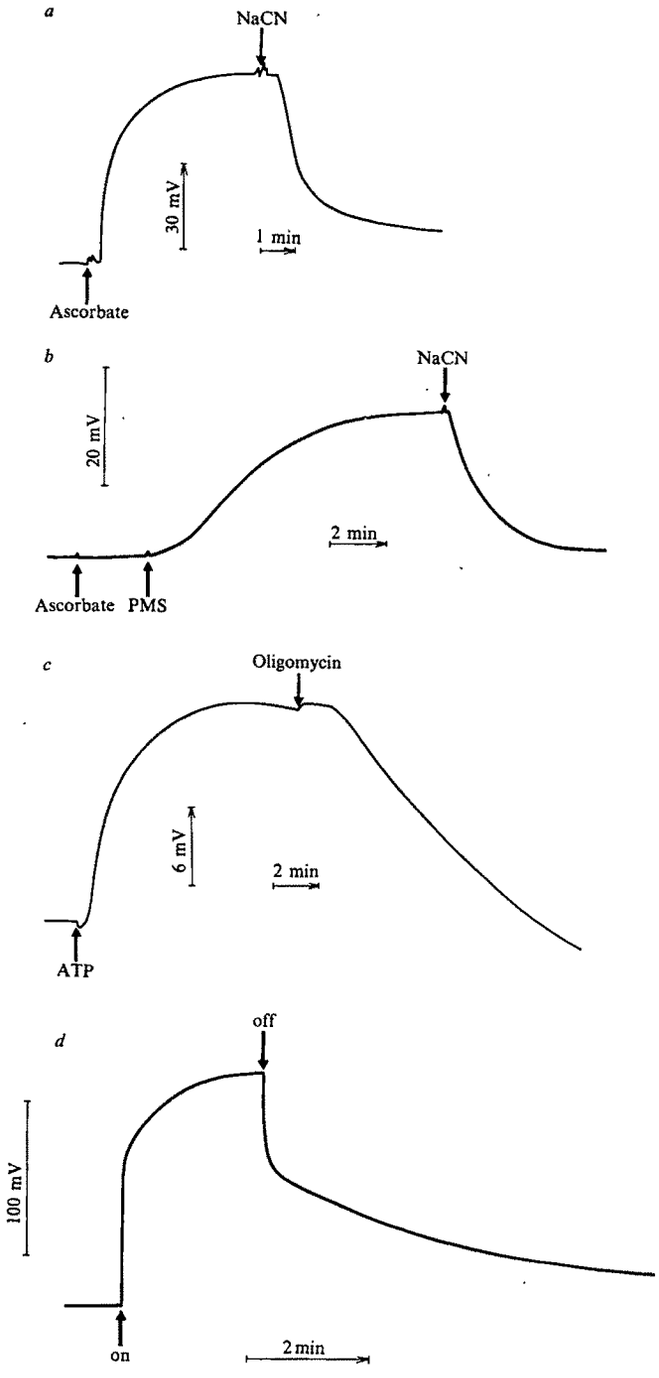

Fig. 1 Generation of transmembrane electric potential differences by cytochrome oxidase (*a*, *b*), H+κ-ATPase (*c*) and bacteriorhodopsin (*d*), *a*, Incubation mixture: 0.3 M sucrose, 5 mM Tris-citrate (*p*H = 7.2), 30 mM $CaCl_2$, 5 mM $MgSo_2$, 1×10^{-4} M cytochrome *c*. One of compartments was supplemented with cytochrome oxidase proteoliposomes (0.3 mg protein ml^{-1}. Additions: 10 mM ascorbate (added in the same compartment as proteolipsomes), 1 mM NaCN (added in both compartments) Planar membrane resistance (R) 1.5×10^{10} ohm, current at maximal potential difference (I) 5×10^{-12} A. *b*, Incubation mixture: 0.2 M sucrose, 0.05 M Tris-HCl (*p*H = 7.2), 30 mM $CaCl^2$, 7×10^{-5} M cytochrome c. One of compartments contained cytochrome oxidase proteoliposomes (0.25 mg protein ml^{-1}). Additions in the proteoliposome-free compartment: ^{5}mM ascorbate, 1.5×10^{-6} M PSM, in both compartments: 1.5×10^{-3} M NaCN. R = 1×10^{10} ohm, I = 2×10^{-12} A. *c*, Incubation mixture: 0.3 M sucrose, 5 mM Tris-citrate (*p*H = 7.2), 30 mM $CaCl_2$, 5 mM $MgSO_2$. One of compartments contained ATPase proteoliposomes (0.3 mg protein ml^{-1}). Additions: 2.5 mM ATP, oligomycin (30 μg ml^{-1}). R = 1×10^{10} ohm, I = 1.8×10^{-12} A. *d*, Incubation mixture: 0.2 M sucrose, 5 mM Tris-HCl (*p*H = 7.2), 30 mM $CaCl_2$, and in one of compartments, bacteriorhodopsin proteoliposomes (0.2 mg protein ml^{-1}). R = 2×10^{10} ohm, I = 7.5×10^{-12} A.

partment with proteoliposomes gives rise to the formation of electric potential difference (minus on the proteoliposome side). Oligomycin reverses the ATP action.

Figure 1*d* illustrates the light-induced generation of an electric field by bacteriorhodopsin proteoliposomes. In this case, minus was on the proteoliposome side. In the dark, the membrane potential dissipated.

In all cases, addition of a protonophorous uncoupler, trichlorocarbonylcyanidephenylhydrazone (2×10^{-7} M) or the shunting of the planar membrane by an external resistance greatly decreased the above responses, and accelerated their dissipation when no more energy was supplied.

The magnitudes of the membrane potential vary depending on the conditions and quality of proteoliposomes. The maximal potential values for cytochrome oxidase were ~ 110 mV, for bacteriorhodopsin ~ 150 mV. In the ATPase experiments, the membrane potentials were always lower, and more time was required for the proteoliposomes and planar membrane to fuse, the fact which may be due to the complex profile of the ATPase proteoliposome surface covered with the F_1 knobs.

Electrical response

The bacteriorhodopsin system has proved to be the most convenient experimental model, because the responses were large, steady and easily reproducible. This system was studied in some detail. In particular, the change of the photoeffect as the function of the potential difference generated across the planar membrane by an external source (ΔV_{ext}) has been measured. It was found (Fig. 2) that ΔV_{ext} of the same sign as that of the photo e.m.f. decreases, and of opposite sign increases, the light-induced response. At a certain ΔV_{ext}, the photoeffect becomes equal to zero. In these conditions, ΔV_{ext} should be equal to the bacteriorhodopsin photo e.m.f. if all bacteriorhodopsin generators have the same orientation. Photo e.m.f. should be higher than this value if some of generators are oriented in the opposite direction to the majority. According to Fig. 2, bacteriorhodopsin photo e.m.f. is $\geqslant$ 300 mV.

It seems most probable that these electrical responses are due to proteoliposomes attached to the surface of the planar phospholipidm embrane. As shown previously[18,19], the addition of Ca^{2+} induces the fusion of two planar phospholipid membranes resulting in the formation of an electrical contact between the membranes and a local decrease in the electrical resistance.

The fusion of proteoliposomes with planar membrane seems to be irreversible. In fact, experiments with the bacteriorhodopsin system showed that the photoeffect, if it appears, is retained after a solution without proteoliposome is substituted for the proteoliposome-containing mixture.

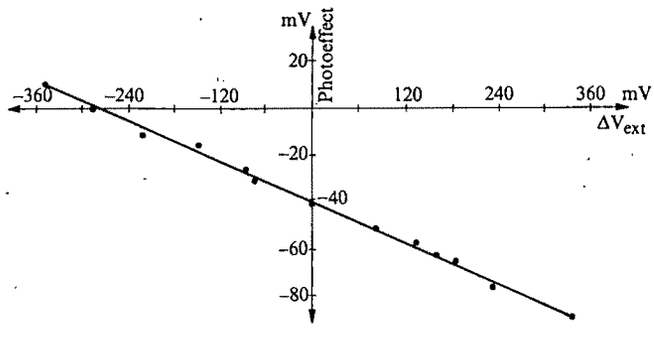

Fig. 2 Relationship between the bacteriorohodopsin-mediated photo effect and external ΔV. Incubation mixture: 0.3 M sucrose, 0.09 M $(NH_4)_2SO^4$, 5 mM Tris-HCl (*p*H = 7, 2), bacteriorhodopsin proteolipsomes in one of compartments (0.1 mg protein ml^{-1}).

Proteoliposomal and planar membrane fusion

The schemes for fusion of proteoliposomal and planar membranes are given in Fig. 3. Figure 3*A* indicates that cytochrome oxidase proteoliposome, associated with a planar membrane, carries out electron transfer from the extraproteoliposomal ascorbate to the intraproteoliposomal oxygen.

As a result, the proteoliposome interior charges negatively. H^+ ions or other cations of the proteoliposome interior move (down the electric gradient) across the proteoliposome membrane from the same compartment (where the proteoliposomes are), or, alternatively, from the opposite compartment situated on the other side of the planar membrane (Fig. 3, dotted lines). The latter situation should give rise to the formation of an electric potential difference across the planar membrane, namely, positive charging of the proteoliposome-containing compartment and negative charging of the opposite compartment. In agreement with this scheme, experiments on the proteoliposomes of different types showed that the proteoliposome-free compartment always charges like the proteoliposome interior. In fact, cytochrome oxidase proteoliposomes with cytochrome *c* inside, ATPase proteoliposomes and bacteriorhodopsin proteoliposomes generate positive charges, whereas the cytochrome oxidase proteoliposomes with cytochrome *c* outside generate negative charges in their interior[16,17]. The first three types of proteoliposomes charge the proteoliposome-free compartment positively, and the last charge it negatively.

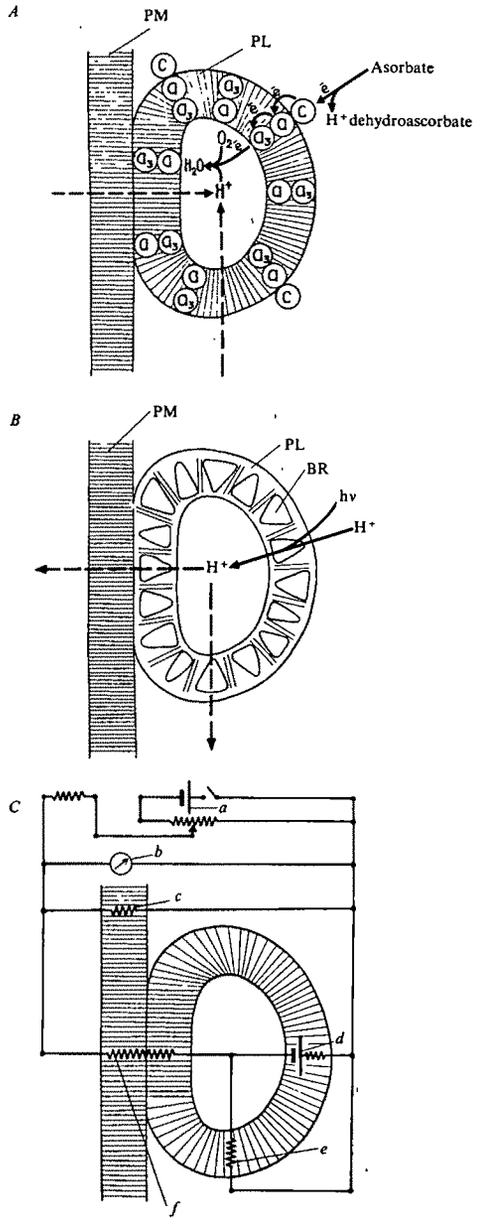

Fig. 3 Schemes illustrating interaction of the proteoliposomes (PL) with the planar membrane (PM). *A*, Cytochrome oxidase proteolipsomes with cytochrome *c* outside. *a*, a_3 and *c*—corresponding cytochromes; *B*, bacteriorhodopsin (BR) proteolipsomes; *C*, equivalent scheme for estimation of e.m.f. of the molecular electric generators. *a*, External battery; *b*, voltmeter; *c*, planar membrane resistance; *d*, molecular e.m.f. generator; *e*, proteoliposome resistance; *f*, resistance of fusion region.

The scheme given in Fig. 3*A* also explains why phenazine methosulphate is required for membrane potential to be supported by oxidation of ascorbate added into the proteoliposome-free compartment. Planar phospholipid membrane is impermeable to ascorbate (shown by special experiments) so reducing equivalents cannot reach cytochrome oxidase, if proteoliposomes and ascorbate are in different compartments, until a lipid-soluble hydrogen atom carrier is added (see Fig. 1*b*).

An important prediction of the scheme illustrated in Fig. 3*A* is the inefficiency of cytochrome oxidases localised in the region of fusion of the proteoliposome with the planar membrane. According to the procedure used in the cytochrome oxidase experiments, cytochrome *c* was added several minutes later than proteoliposomes, so that the fusion preceded the reconstitution of the cytochrome *a*–cytochrome *c* complex. Moreover, ascorbate concentration should be very low in the fusion region because of hydrophilic properties of this compound. Low membrane permeability for ATP and H^+ can be responsible for ineffectiveness of ATPase and bacteriorhodopsin molecules in the fusion region, respectively.

In the reconstitution of proteoliposomes, transmembrane orientation of proteins may be of two opposite directions. To actuate the systems oriented in one of these directions, non-penetrating substrates or catalytic factors may be used: ascorbate and cytochrome *c* in the case of cytochrome oxidase proteoliposomes; ATP and factor F_1 in the case of ATPase proteoliposomes. Asymmetric reconstitution of the bacteriorhodopsin proteoliposomes (Fig. 3*B*) may be a result of the difference in areas of the inner and outer surfaces of the vesicles (for discussion, see ref. 17).

In Fig. 3*C*, the equivalent electric scheme of the experiment on estimation of the e.m.f. of the molecular electric generators is given.

We wish to thank Professor Yu. A. Ovchinnikov for advice and Professor L. P. Kayushin and Dr L. N. Chekulaeva for providing *Halobacterium halobium* cells.

This study was carried out within the framework of the Project 'Rhodopsin' organised by the USSR Academy of Sciences and Moscow State University and supervised by Professor Yu. A. Ovchinnikov.

Contractile units in vertebrate smooth muscle cells

J. V. Small*

Department of Zoology, Melbourne University, Parkville, 3052, Australia.

Evidence from isolated smooth muscle cells in rigor indicates that the contractile elements are grouped into separate fibrils or 'contractile units' arranged obliquely with respect to the cell axis.

FROM X-ray diffraction studies[1,2] of living vertebrate smooth muscle, the presence of myosin filaments during both relaxation and contraction is generally accepted but the form and arrangement of these filaments within the cell is far from settled. This latter dilemma arises because the appearance of the contractile apparatus as observed in electron microscope studies of whole muscle is extremely variable[3–15], a situation which derives mainly from the marked lability of the myosin-containing filaments under conditions of chemical fixation.

Another approach to the problem of smooth muscle structure was suggested by the demonstration[16] that viable smooth muscle cells which retain their spindle-like shape may be separated from toad stomach by conventional cell separation methods, utilising collagenase and trypsin. These cells were shown to contract on electrical stimulation[16,17]. If model cells could be produced from such preparations, corresponding to isolated myofibrils from striated muscle, whose ability to contract could be controlled through the external environment, then the contractile apparatus should be more accessible to both fine structural and biochemical studies. The same sort of approach has been particularly fruitful in investigations of nonmuscular motile systems[18–20].

With this object in mind, experiments were carried out to develop methods for the preparation of cells from smooth muscles such as chick gizzard, guinea pig taenia coli and guinea pig vas deferens which have already been the subject of several ultrastructural and biochemical investigations. The results from the first stage of this study are summarised in the present report. They show that under conditions whereby the cell membrane is made permeable, either through the cell dispersion process itself, by treatment with the nonionic detergent Triton X-100 or by glycerination, a very regular organisation of obliquely arranged birefringent fibrils is seen in the light microscope. From the ability of such cells to contract in the presence of ATP it is proposed that these fibrils represent the elemental 'contractile units' of the vertebrate smooth muscle cell.

The fibrils

Gizzards from chicks 2–3 weeks old, were thinly sliced and then diced into small pieces in Solution 1, a modified Hanks solution (NaCl, 137; KCl, 5; Na_2HPO_4, 1.1; KH_2PO_4, 0.4; $NaHCO_3$, 4 and glucose, 5.5 mM, respectively; Mg^{2+} and Ca^{2+} ions absent) buffered additionally with PIPES 5 mM (*p*H 7.1 – 7.4) and with added EGTA (2 mM). (The effect of EGTA was two fold: it acted first as a relaxant so that cells could be obtained at an extended length and second as an effective pretreatment for subsequent cell dispersion by collagenase[21].) In some experiments EGTA was replaced by hyoscine (10^{-6} g ml^{-1}). After 2–4 h at room temperature the muscle pieces were then transferred to 10–20 ml of a solution containing 1 mg ml^{-1} collagenase (Worthington CLS or Sigma type I) of the same composition as above except that EGTA and phosphate were omitted and $CaCl_2$ (5 mM) added to activate the enzyme. With slow stirring at 37° C up to three cell collections were made at 1 h intervals, fresh reaction solution being added to the muscle pieces after each harvest. The cells were gently pelleted and washed and stored in Solution 1.

In the light microscope these preparations showed a mixture of whole cells and cell fragments (Fig. 1*a*). The striking feature of both of these components was that they nearly all exhibited, in phase contrast, a regular criss-cross pattern of fine fibrils within the cytoplasm (Fig. 2*a*). The fibrils normally averaged about 0.4 μm in width (range 0.3 – 0.5 μm) with an average separation between parallel neighbours of about 0.9 μm (range 0.8 – 1.1 μm).

Evidently, for the cell fragments, the intracellular contents were in direct contact with the bathing medium and from the following observations it was concluded that the whole cells had also been rendered permeable by the separation procedure. The intense reddish colour of gizzard which is due predominantly to an intracellular pigment and not to the vasculature supplying this tissue, is gradually lost from the muscle pieces and is absent from pellets of the isolated cells. In addition, placing the cells in solutions of widely varying osmolarities caused no change in their dimensions. These general conclusions about the permeability of gizzard cells isolated with collagenase are consistent with the recent results of Kominz and Gröschel-Stewart[22].

In conditions for which the sarcolemma is disrupted and ATP and other soluble components lost from the cell, striated muscle adopts the well known 'rigor' state in which myosin crossbridges are firmly bound to actin[23]. That the cells from gizzard had adopted a similar rigor-like state was confirmed by unsuccessful attempts to stimulate them with a microelectrode (experiments carried out in collaboration with Dr R. Purves). Pushing the cells along with the microelectrode tip revealed that they were extremely stiff, rigid structures.

Among the various other methods tried, glycerinated gizzard pieces (immersed in 50% glycerol, 80 mM KCl, 5mM PIPES, *p*H 6.5 with or without 0.5 mM dithiothreitol and stored at −20° C for 4–6 weeks) were dissociated in the same manner as described above for fresh muscle. Such experiments yielded, by comparison with fresh muscle, a rather low proportion of 'intact' cells. These cells, however, showed the same regular fibrillar pattern as illustrated in Fig. 2.

In general, the mitochondria and nuclei in the gizzard myofibrils were rather swollen and sometimes partly obscured the fibrillar organisation. These organelles could

Fig. 1 Isolated cell preparations (phase contrast) *a*, Chick gizzard cells and cell fragments (× 165); *b*, cells separated from extended taenia coli muscle (0.02% Triton X–100); average cell length 450 μm (× 218); *c*, cells separated from short taenia coli muscle (0.02% Triton X–100), average cell length 115 μm × 297).

however, be removed by brief treatment of the cells with the nonionic detergent Triton X-100 (0.1% (v/v) in Solution 1) to yield 'clean' cells showing only the presence of the fine fibrils (Fig. 2*b*).

For adult guinea pig taenia coli and vas deferens, a different result was obtained when using essentially the same procedure for these muscles as employed for fresh gizzard. Collagenase treatment (carried out by necessity in the presence of Ca) caused the cells in these muscles to shorten, and, if the treatment was long enough, to round up. Such shortened cells could then be grown successfully in tissue culture indicating that, in contrast to the gizzard cells, their membranes had not been ruptured by the separation procedure. But because of their short and irregular form, these cells were unsuitable for structural studies.

Rupture of cell membranes

As one means of obtaining cells at their *in situ* length, methods were employed to deliberately rupture the cell membranes before or during collagenase treatment on the assumption that this would induce them directly into a rigor-like state, comparable to that found for gizzard. This was most readily achieved by the addition of Triton X-100 during incubation of the muscle in collagenase. Of the various concentrations tried, the most suitable were found to be 0.01 – 0.03% (v/v) for taenia coli and 0.1% (v/v) for vas deferens. It was also found more satisfactory to leave these muscles intact and tie them at the desired length to plastic plates during processing in collagenase. After collagenase treatment and after transfer to Solution 1, the cells could be teased from the muscle with fine needles. A more detailed account of the various methods used will be described elsewhere.

The type of preparation obtained in this way from taenia coli muscles extended to their maximal length in the presence of EGTA is shown in Fig. 1*b*. The cells are very long, straight and spindle-shaped and, although not visible in this micrograph, their nuclei are intact. The extended length of cells from taenia coli averaged 450 μm (77 cells—range 320–570 μm) with a corresponding nuclear length of between 30 μm and 50 μm.

At relatively low magnifications with phase contrast microscopy (×300–×500), the cell cytoplasm appears essentially homogeneous but using a ×100 oil immersion objective (total magnification about ×1250) a regular fibrillar pattern is clearly resolved. Observation by polarisation optics showed the fibrils to be strongly birefringent and in these conditions they are most clearly demonstrated (Figs 3*c* and 4).

The average width of the fibrils was about 0.3 μm (range 0.26–0.39 μm) and the centre-to-centre separation between parallel neighbours about 0.5 μm (range 0.45–0.58 μm). No abrupt discontinuities such as banding could be detected along a single fibril.

Taenia coli strips shorten spontaneously at 37° C in a normal balanced salt solution or in a similar medium such as used here for collagenase digestion. Treatment of such strips with collagenase together with Triton X-100 as above yields shortened cells (Fig. 1*c*). The average length of these shortened cells was about 115 μm (100 cells—range 65–160 μm). In these cells the fine fibrils were seen to be considerably more oblique (Fig. 3, *a* and *b* forming angles up to about 24° (at about 115 μm) with respect to the

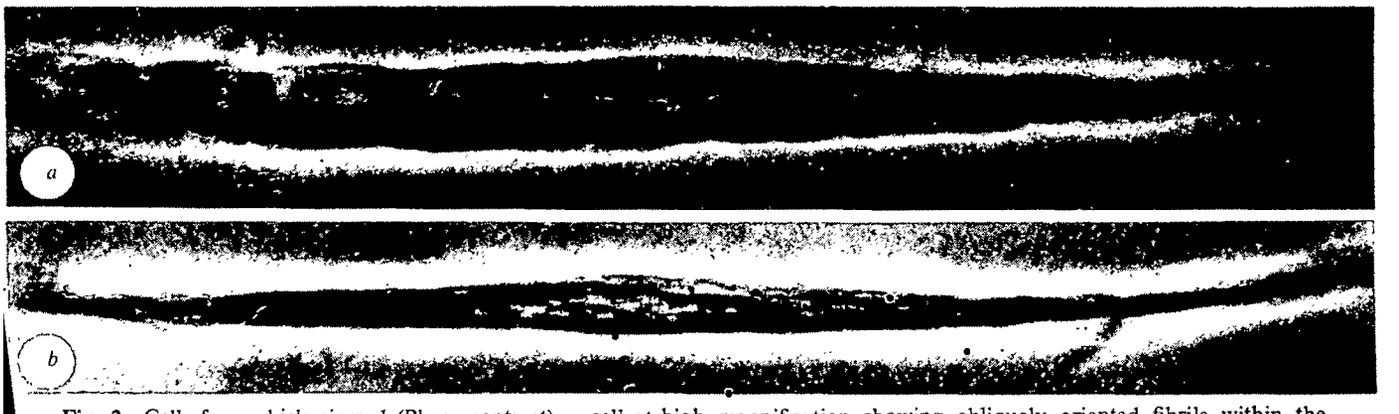

Fig. 2 Cells from chick gizzard (Phase contrast) *a*, cell at high magnification showing obliquely oriented fibrils within the cytoplasm (× 1246); *b*, gizzard cell from a preparation treated additionally with Triton X-100 (see text), again showing the fibrils (× 774).

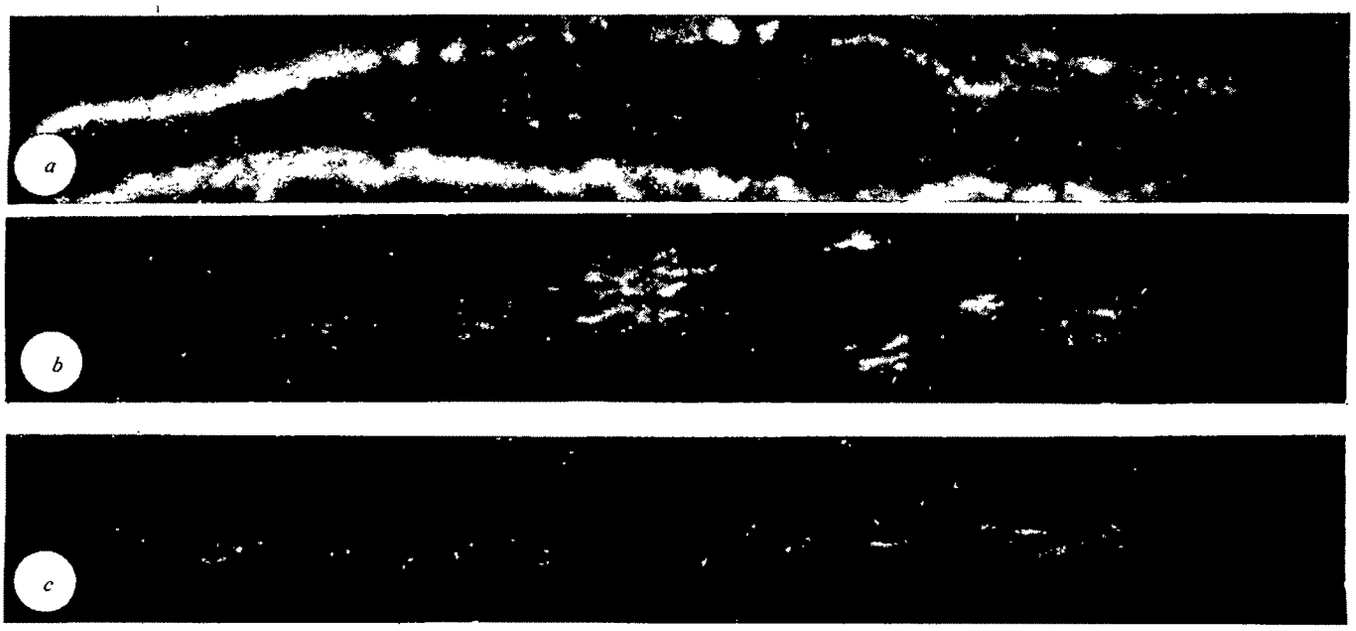

Fig. 3*b* and *c*, short cell from taenia coli (from a preparation such as shown in Fig. 1*c*). The cell length is about 90 μm. The fibrils are considerably more oblique with respect to the cell axis as compared to the extended cells (Figs 3*a* and Fig. 4). Polarisation optics and phase contrast respectively (× 1970). *c*, Part of an extended taenia coil cell (from a preparation such as shown in Fig. 1*b*) observed with polarisation optics. The fibrils are birefringent and subtend angles up to about 5° with respect to cell axis (× 2340).

cell axis, as compared to about 5° in the extended cells (Fig. 3*c*)). Cells could also be found which had contracted to as short as about 35 μm. These supercontracted cells had an irregular outline and their fibrils subtended angles up to 40° with respect to the cell axis. Cells from the vas deferens contained fibrils of similar dimensions to those observed in the taenia coli cells.

By comparison with the taenia coli and vas deferens, the fibrillar pattern in the gizzard cells was as already indicated, normally rather coarse and could be recognised at quite low optical magnifications. It was, however, not uncommon to find cells with a much finer fibrillar lattice with fibrils having a similar width to those observed in the taenia coli muscle. Some variation in fibril width was also recognised, but to a lesser extent, in cells from the taenia coli and vas deferens. The reason for these differences is at present unknown, but indicates that some subdivision or association of fibrils can occur.

Response to ATP

Efforts to cause gizzard and taenia coli cells to contract showed that they were capable of shortening in the presence of ATP. Cells suspended under a coverslip in 80 mM KCl, 4 mM $MgCl_2$, 5 mM PIPES, *p*H 6.5–6.8, could be induced to contract by the addition of 0.1–4 mM ATP in the same buffer to the coverslip edge.

The cells reacted to ATP by slowly shortening over a variable time period, but which was at the shortest in the order of about 1 min. Cells from taenia coli shortened to an average length of about 65 μm (40 cells, range 40–100 μm).

The changes in appearance of the cells that accompanied contraction as seen under phase contrast conditions were slightly variable and for taenia coli, two different responses could be recognised. In one case the initiation of contraction was accompanied by a roughening of the cell, apparently on its surface. Although this roughening effect tended to mask the internal details of the cell it seemed that there was also an associated change in the fibrils such that they could no longer be recognised, a situation which persisted throughout contraction.

In the second case, ATP caused a slight swelling of the cells, followed by slow shortening. In this situation the fibrils were seen to disperse and the cells became rather transparent. Roughening of the cell outline occurred as the cells approached their shortest length. For the gizzard preparations, the response was of the latter type described for taenia coli. After shortening had ceased, cells could then be found in which firils were again clearly visible and which then showed a considerable obliqueness with respect to the cell axis (that is, as in Fig. 3*a* and *b*).

In some cases, particularly with gizzard, the addition of ATP did not always produce contraction. With several preparations ATP addition caused some, or all, of the cells to swell up or to completely dissolve. Possible reasons for this variable response are the subject of further investigations. Of additional interest was that the inclusion of EGTA (2 mM) in the ATP-testing medium to chelate any contaminating calcium did not affect contraction in any way. This suggested that the Ca^{2+} regulatory mechanism of vertebrate smooth muscle[24,25] (R. D. Bremel and A. Sobieszek, M. K. Reedy, unpublished), had been lost or rendered ineffective during the cell preparation procedure.

Relaxed cells

By the use of ATP (0.5 mM) instead of Triton in the collagenase medium, extended cells were obtained from taenia coli which were similar in general appearance to the cells obtained from toad stomach by Bagby *et al.*[16] and Fay and Delise[17], being smoothly curved along most of their length. From their observed movement on a slide in a stream of bathing medium, these cells were seen to be very flexible, in contrast to their rigid counterparts obtained with Triton. Furthermore, they were found to shorten immediately on transfer from the EGTA-containing medium (Solution 1) to one in which EGTA was replaced by Ca^{2+}. This shortening could, alternatively, be observed under the microscope by the addition of the medium containing Ca^{2+} to the coverslip edge.

From these findings it was apparent that the cells obtained with ATP were essentially intact and could be considered, in the absence of Ca^{2+}, to be in a 'relaxed' state (The effects of ATP and calcium in this instance will be considered in detail elsewhere).

Under phase contrast or with polarisation optics, fibrils could not be recognised in these relaxed cells, neither could they be observed under phase contrast during contraction with Ca^{2+}.

The contractile apparatus

The present results represent the first demonstration in the light microscope of a regular fibrillar organisation within the vertebrate smooth muscle cell. Fibrils of similar dimension were often described in the early literature on smooth muscle[26–28] but were not seen to form any regular pattern within the cell. It is not unlikely that what the early histologists observed was a distorted arrangement of the fibrils described here.

From the ability of the cells to contract with ATP it is clear that the presence of the fibrils is not artifactual but represents a significant state of the contractile apparatus. As already indicated this state may be considered as essentially equivalent to rigor in striated muscle. In a very recent study, Kominz and Groschel-Stewart[22], using a similar technique, obtained isolated cells from gizzard which, by the use of an 'electric-sizing technique' were also shown to contract with ATP. But these authors did not report the presence of fibrils within the cells.

The most reasonable interpretation of the fibrillar pattern is that it reflects directly the gross organisation of the contractile apparatus. Thus, the contractile elements (the thick and thin filaments etc) are considered as being grouped into fibrillar units, that is the fibrils, within the cell. Furthermore, as there was no evidence for interconnections between the fibrils, it is most likely that each fibril represents a separate contractile unit, presumably attached at either end to the cell surface. These units are arranged obliquely across the cell and contraction is achieved by a shortening of the fibrils, which themselves, as a result of shortening, become progressively more angled with respect to the cell axis. Such changes in fibril orientation are fully consistent with the known decrease in birefringence of smooth muscle on shortening[29] and with the noted disorientation of myofilaments in the shortened cell[17].

The changes that occur when cells pass from rigor to the contracting state and which lead to a loss in visibility of the fibrils, clearly involve changes within the fibrils themselves. Myofibrils obtained from glycerinated striated muscle tend to swell when passing from rigor to the relaxed state[30]. A similar swelling response to ATP would cause the fibrils here to become both less refractile as well as closer neighbours, changes which could render them undetectable by light microscopy. From the results on 'relaxed cells' it is presumed that rather smaller changes occur in fibril dimensions between relaxation and contraction.

I suggest that the results presented here represent a significant step towards elucidating the organisation of the contractile apparatus of vertebrate smooth muscle. There is now strong evidence for an ordered grouping of the contractile elements into separate contractile units. On this basis, the problem of the mode of contraction in this muscle type reduces, in the first instance, to that for an individual fibril. Continuing studies are being aimed at further defining the functional significance of the fibrils and their detailed structural organisation.

Fig. 4 A group of extended taenia coli cells (as in Fig. 3*a*) showing the fibrils. Polarisation optics (× 1162).

I thank Professor G. Burnstock for providing the facilities for this research and thank him and Drs G. Campbell and A. Sobieszek for discussion and criticism of the manuscript. I thank Miss J. McConnell for assistance with tissue cultures, Mr B. Pump for photography and Mrs G. Liddell for typing. The author acknowledges the generous support of the Danish Science Research Council and the Zoology Department for travelling expenses. This work was supported in part by funds from the National Heart Foundation of Australia and the Australian Research Grants Committee.

Received October 1, 1973; revised January 10, 1974.

Note added in proof: By Triton treatment, in the presence of dithiothreitol, of 'relaxed' cells from taenia coli (produced with ATP) cells may be obtained which exhibit the same fibrillar organisation as cells rupture during collagenase treatment and which, further, show sensitivity to Ca^{2+} ion for contraction.

Relative-distance Machian theories

MACH's principle, in essence, requires that the dynamical law of the Universe be expressed ultimately in terms only of the relative distances between the observable entities in the universe. Here I propose a general framework for constructing theories that satisfy this postulate automatically. A simple model shows how the Newtonian world picture can be satisfactorily 'Machianised.' In principle, one could attempt to Machianise the post-1905 world picture along similar lines.

The key Kinematic concept is the relative configuration space (RCS) of the Universe. If, as in Newtonian theory, the Universe is assumed to consist of N particles in a fixed three-dimensional Euclidean space, the points of the RCS (the Newtonian RCS) are all the distinct relative configurations of these N particles. Many other RCSs are conceivable. For example, the points of an RCS could be all distinct three-geometries, and the RCS would then be the 'superspace' familiar in general relativity[1]. The general framework is not, therefore, tied to pre-1905 physics.

A kinematical history of the Universe (or RCS curve) is any continuous curve in the RCS. On any such curve, each point defines an 'instant of time' in the given history; the unfolding of time is but the fact of the universe's moving along some RCS curve (Leibniz's concept of time). Note that time — and therefore the possibility of defining relative velocities — is derived from within the RCS; note also the emphasis that is placed on the motion of the Universe as a whole.

If the dynamical law of the Universe is expressed solely in terms of elements taken from within the RCS, the theory must be Machian by construction. This is the general criterion that a Machian dynamics must satisfy. One possibility of realising such a dynamics is to seek a variational principle that contains only allowed kinematical elements and makes actually realised RCS curves extremal compared with neighbouring kinematically allowed curves. The initial conditions are specified by the direction of the RCS curve at a given point of the RCS. Boundary conditions do not arise.

In the case of the Newtonian RCS, space will play a geometrical but not dynamical role (in contrast to Newtonian mechanics). In a theory in which three-geometries constitute the points of the RCS, a Machian dynamics would automatically entail a variable three-geometry that unfolds in accordance with a Machian law. In this case, it would be more appropriate to speak of a relative-configuration (rather than relative-distance) Machian theory. Such an approach is not identical to the superspace approach to general relativity, in which it is assumed *a priori* that a sequence of three-geometries 'stacks' into a four-dimensional Riemannian space[1]. I see here the extraneous element (not taken from within the RCS) responsible for general relativity's failure to give an entirely satisfactory account of inertia.

It seems difficult to reconcile the universal time defined here with the local time of special relativity. But the flat-space approach to general relativity[2,3] has shown how the *a priori* assumed kinematical elements of a theory can, in fact, be rendered inobservable when a dynamical law of gravitation is imposed on a prescribed kinematical structure. In principle, something similar could happen here — a dynamical law, perhaps in conjunction with a particular class of plausible initial conditions, could lead to a dynamics in which only a local time can in fact be observed. The present approach reverses the priorities that Einstein had in mind when constructing general relativity. Instead of requiring special relativity to hold in the small under all conceivable circumstances in all possible universes (and hoping that this can somehow be reconciled with Mach's principle *via* the equivalence principle), the aim here is to construct theories that are Machian of necessity and then to see if any of these give rise to special relativity in the small in universes like ours.

In the case of a Newtonian RCS with N point particles $i = 1, \ldots, N$ of mass m_i (an intrinsic number associated with each particle; $\Sigma m_i = M$), the obvious allowed kinematical elements are the relative distances $r_{ij}(\lambda)$ between all pairs i and j of particles, and their derivatives $\dot{r}_{ij} = \mathrm{d}r_{ij}/\mathrm{d}\lambda$ with respect to an arbitrary time parameter λ along the RCS curve. The simplest nontrivial gravito-inertial dynamics is then defined by the Lagrange function

$$L = \psi\Gamma \tag{1}$$

where

$$\Gamma = \Big(\sum_{i<j} m_i m_j \dot{r}_{ij}^2\Big)^{1/2}, \quad i = 1, \ldots, N$$

$$\psi = \sum_{i<j} m_i m_j / r_{ij}$$

Equation (1) has a product form to ensure that $L\mathrm{d}\lambda$ is independent of the time parameter (a sum like $(\psi + \Gamma)\mathrm{d}\lambda$ would not be λ-independent).

The equations of motion deduced from (1) in three dimensions are too complicated to be readily comprehensible. Simple equations are obtained in one dimension by introducing Cartesian coordinates, whose origin may execute any suitably continuous motion whatsoever relative to the particles in their one-dimensional universe. The resulting Euler-Lagrange equations will describe the uniquely determined relative motion (which is all that is observable) in terms of the arbitrarily chosen coordinate system. Let $x_i(\lambda)$ be the coordinate of particle i; then L becomes

$$L = \psi\Big[\sum_{i<j} m_i m_j (\dot{x}_i^2 - 2\dot{x}_i\dot{x}_j + \dot{x}_j^2)\Big]^{1/2} \tag{2}$$

and the Euler-Lagrange equations

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}(\partial L/\partial \dot{x}_i) = \delta L/\partial x_i$$

are

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}\left\{\frac{\psi m_i}{\Gamma}\left[\sum_{j\neq i} m_j(x_i - x_j)\right]\right\} \equiv$$

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}\left\{\frac{\psi m_i}{\Gamma}\left[\dot{x}_i(M - m_i) - \sum_{j\neq i} m_j\dot{x}_j\right]\right\} = \frac{\Gamma\partial\psi}{\partial x_i}$$

We can now specialise both λ, taking

$$\mathrm{d}\lambda = \mathrm{d}s = \Big(\sum_{i<j} m_i m_j \mathrm{d}r_{ij}^2\Big)^{1/2}, \quad \text{i.e. } \Gamma \equiv 1,$$

and the coordinate system, taking it such that

$$\Sigma m_i x_i = 0 \text{ (here } \mathrm{d}\lambda = \mathrm{d}s)$$

In these special frames, which are distinguished by the uniquely determined relative motion, the equations of motion simplify to

$$M\frac{\mathrm{d}}{\mathrm{d}s}(\psi m_i \dot{x}_i) = \frac{\partial\psi}{\partial x_i} \tag{3}$$

If only a few particles are present in the Universe, equations (3) clearly lead to motion that is very different from the Newtonian. On the other hand, in an environment broadly similar to ours (very many stars distributed uniformly over a large region), ψ

will be effectively constant and s will be indistinguishable from Newtonian time. Then equation (3) becomes

$$m_i \, d\dot{x}_i/dt = (1/M\psi)\partial\psi/\partial x_i \quad (4)$$

where $\gamma = 1/M\psi$ is a 'gravitational constant' that is determined by the actual distribution of matter in the Universe. A different model (in preparation) turns out to have more interesting properties, so I shall not attempt to estimate γ here. In the neighbourhood of the Sun, say, the motion predicted by equation (4) is essentially indistinguishable from the Newtonian if γ has the correct value.

This model is, I believe, interesting for several reasons. First, it explains inertia (resistance of a body to rectilinear acceleration relative to the remaining bodies in the Universe) solely in terms of relative distances and relative velocities and demonstrates that a complete dynamics can be expressed in such terms. For the discussion of how Mach's principle should be implemented, this may be important, for Einstein, in particular, doubted whether the Newtonian world picture could be Machianised in this manner[4]. It is particularly satisfying that preferred frames (the inertial frames of Newtonian theory) are distinguished by a motion whose dynamics is expressible solely in terms of relative distances.

Second, although two features of Newtonian gravitation are introduced *a priori* in equation (1) — all gravitational 'charges' are of the same sign and are proportional to the inertial 'masses' — the theory itself determines the actual strength of gravity (because a coupling constant cannot enter the product L) which must be attractive. (In the model in preparation, gravity and inertia are truly subsumed into a single mechanism and the correct order of magnitude of the gravitational constant is predicted.)

Third, whereas Newtonian theory and general relativity provide equations of motion for essentially inobservable quantities in the limit of universes containing only a few particles, no such problem arises in the present approach. If there is just one particle in the Universe, the RCS does not even exist, so there is no theory at all. If there are two particles, the RCS is the positive half axis, but no equation of motion can be formulated because equation (1) becomes trivial; the particles may approach or recede but no meaning can be attached to the rate at which this happens. Nontrivial dynamics first becomes possible when there are three particles, and even then the motion is quite unlike the Newtonian. Many particles in an isotropic background are required to build up the inertial forces as we know them in this universe.

Other forces could be included readily by adding a term linear in the r_{ij}s to L (gyroscopic-type forces) or multiplying L by another factor $\Phi = \Phi(r_{ij})$. Indeed, in an attempt to include electrostatics, take $L' = \Phi\Psi\Gamma$, where $\Phi = \sum_{i<j} e_i e_j / r_{ij}$, with $e_i = 1$ for $i = 1, \ldots N/2$ and $e_i = -1$ for $i = N/2 + 1, \ldots N$. Then the equations of motion corresponding to the conditions under which equation (4) hold are

$$m_i \, d\dot{x}_i/dt = (1/M\Psi)\,\partial\Psi/\partial x_i + (1/M\Phi)\,\partial\Phi/\partial x_i \quad (5)$$

As L' is a product, the relative strength of the new forces is again determined by the theory for each particular universe. In fact, if the particles in this case have equal masses and are distributed more or less uniformly, then $|\Psi/\Phi| \sim N$, because all the $\sim N^2$ terms in Ψ are positive, whereas there are just N more negative than positive terms in Φ. Thus, the electrostatic forces in equation (5) are $\sim N$ times stronger than the gravitational forces and like charges repel and opposites attract (provided $\Phi < 0$; I do not know whether distributions could exist for which $\Phi > 0$). As it happens there are $N \sim 10^{80}$ baryons in the observable Universe[5], whereas we require a strength ratio $\sim 10^{40}$, but the fact that we get the square of the right answer is perhaps an indication that product Lagrangians, which arise naturally (if not uniquely) in such a global approach to motion, could perhaps provide an explanation for the famous cosmic coincidences[5].

If the general framework is in fact the right approach to the problem of inertia, radical changes in theoretical physics are almost certainly necessary, and it is unlikely that the simple model presented here could bear any more resemblance to an ultimately successful theory than Bohr's original model of the hydrogen atom does to modern quantum field theory.

I thank D. Sciama, C. Misner, K. Kuchar, D. Raine, and R. Breuer for discussions and encouragement and the referee for helpful comments.

Upper mass limit for quasar

The radio source 4C11.50=1548 + 115 is reported to be a pair of quasars only 5 arcs apart[1,2]. One quasar, 4C11.50a, has a redshift $z = 0.4359$ and is approximately 17 mag, the second quaser, 4C11.50b has a redshift $z = 1.901$ and is an object of 19 mag. I wish to point out that if the redshifts are cosmological the mass of 4C11.50a must be less than about $4 \times 10^{12} M_\odot$.

The light ray from the more distant b passes close to a. The impact parameter for the light ray depends somewhat on the cosmological model but may be taken as about 40 kpc ($H_o = 50$ km s^{-1} Mpc^{-1}). If a quasar has a mass as large as a giant galaxy then the gravitational deflection of the light ray may be noticeable. Gravitational imaging has been discussed at length by many authors but the discussion presented by Press and Gunn[3] is entirely adequate for this consideration. For simplicity, it can be assumed that both quasars are point masses and point light sources. When a light ray from a distant quasar b passes close to the quasar a then two images of b may be seen located on opposite sides of a. When a, b and an observer are exactly aligned, then b is seen as a ring with quasar a located at its centre. The angular radius of the ring, φ_o, is of the same order of magnitude as the deflection angle of the light ray. Therefore, there is an approximate relationship: $\varphi_o \approx 2'' \, (M_a/M_\odot)/(l/R_\odot) \approx 5 \times 10^{-8''} \, (M_a/M_\odot)/(l/pc)$, where M_a is the mass of the quasar a and l is the impact parameter. If a, b and the observer are not exactly aligned, then the observer sees two images of b. If the angular separations from a of the brighter and the fainter image are φ_1 and φ_2 respectively, then

$$\varphi_1 > \varphi_0 > \varphi_2$$

Combining the two relationships provide an estimate of the mass of a:

$$M_a/M_\odot < (\varphi_1/5 \times 10^{-8''})/(l/pc)$$

The observed image of 4C11.50b is almost certainly the brighter, as there is no other object visible within about 1 arc min on the opposite side of 4C11.50a (ref. 2). Inserting $\varphi_1 = 5''$, $l = 4 \times 10^4$ pc into the latter formula gives an upper mass limit for the quasar 4C11.50a:

$$M_a < 4 \times 10^{12} M_\odot$$

This mass limit is not excessively large. Combining the observed luminosities for cluster galaxies of the first rank[4] with the luminosity-to-mass ratio for ellipticals[5] gives masses of $10^{13} M_\odot$.

If it were possible to detect the second image of 4C11.50b the mass of 4C11.50a could be calculated. For the point-mass scatterer there is a simple relationship between the luminosity ratio and the separation ratio of the two images[3]. If the observed ratios did not agree with those predicted for the point

masses then information could be obtained about the mass distribution around the quasar 4C11.50a. If quasars are active nuclei of giant galaxies[6] the existing observations indicate that the total mass within 40 kpc of the nucleus of 4C11.50a is less than about $4 \times 10^{12}\ M_{\odot}$. There is a weak emission in 4C11.50a at the same wavelength as a strong CIV emission in 4C11.50b (ref. 1). It may be because of the unresolved second image of 4C11.50b.

I thank Professor W. Zonn for informing me about the discovery of a close pair of quasars.

Transit of Mercury across the solar disk

THE transit of Mercury across the solar disk on May 9, 1970 (4 h 20 min 30 s – 11 h 12 min 0 s UT), was observed by recording the radio emission at a wavelength of 8 mm using a 22-m paraboloid radio telescope[1]. The pencil beam of the antenna is of width $D=1'.6$ and the sensitivity of the radiometer $\simeq 1.5$ K. The antenna was steered so that Mercury was in the centre of the beam. Mercury obscures the inhomogeneities of radio emission when passing across the solar disk and some fluctuations of the flux of radio emission can occur. The characteristic time of these fluctuations and their amplitude characterise the sizes and temperatures of condensations respectively. In Fig. 1 we show a sample of original (averaged over 15 s) records of fluctuations during the passage of Mercury across the relatively active regions on the disk. Similar records, but with slightly slower fluctuations of smaller amplitude have been obtained for quiet regions of the disk. The auto-correlation curves for active (A) and quiet (Q) regions (Fig. 2) reveal details of the nature of the emission.

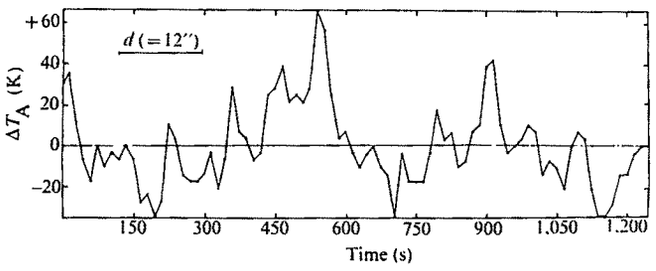

Fig. 1 Fluctuations of radio noise observed as Mercury transits the Sun.

For Q regions the characteristic sizes corresponding to maxima are 3″.4 for the lag $m=0$ and 32″.2 and 41″.3 for the lags $m=44$ and $m=53$. We note that the characteristic size l of condensations is approximately determined from the relations: $l=V\tau_m/2$, if $d>1$, and $l=V\tau_m-d$ when $d<1$, where $\tau_m=m\Delta t$, ($\Delta t=15$ s), v is the velocity of the transit of Mercury across the disk ($=0''.067\ s^{-1}$) and d is the size of Mercury (12″). (We assume, of course, that the size of condensations of the order of the spacing between them).

For A regions the corresponding maxima appear at lags $m=0$, 5, 29, and 36 which correspond to the sizes 1″.8, 2″.51, 17″.4, and 24″.2, respectively. Condensations in A regions are a little more compact than in Q regions. The smallest condensations in both regions have a size of 2″ to 3″ which coincides with the size of smallest 'elements' of the general magnetic field[2]. The group of larger condensations (from 17″ to 41″), although in the size range characteristic of larger 'elements' of general magnetic fields, reflects, we believe, the characteristic sizes of chromospheric supergranules (10^4 to 3×10^4 km[3]).

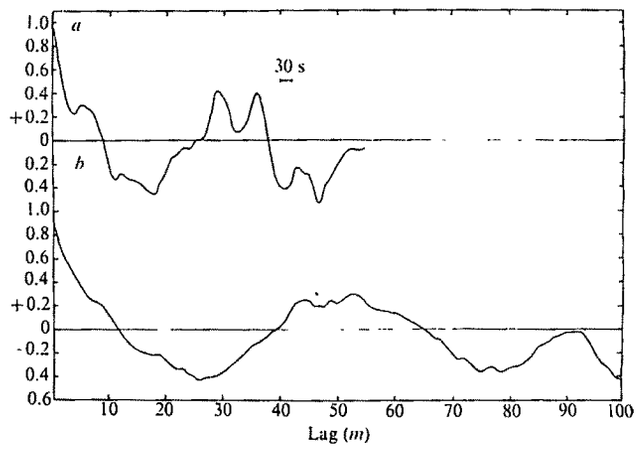

Fig. 2 Autocorrelation curves for: *a*, A region; *b*, Q region.

The characteristic amplitude of fluctuations or excess of brightness temperature ΔT_B over the background (temperature $T_{B0}=8{,}000$ K for $\lambda=8$ mm) determined as the r.m.s. of all fluctuations (deviations from the mean) depends on the ratio d/l and the value of D, and also on the character of eclipse ('central' or 'partial') of condensations by Mercury. The corresponding approximate formulae for excess of antenna temperature ΔT_A are $\Delta T_A \simeq (d^2/D^2)\ \Delta T_B$ when $d<l$ and

$$\Delta T_A \simeq 2\,(d/l)/(D/l)^2 \Delta T_B$$

when $d>l$. The brightness temperature excess ΔT_B for small condensations ($l<3''$) is $\simeq 5{,}000$ K in Q regions and 8,950 and 6,420 K in two observed A regions. For large condensations connected with supergranules the corresponding temperatures ΔT_B are 2,830 K for Q regions and 2,690 for A regions. As the background temperature is 8,000 K the true brightness temperature 8,000 $+\Delta T_B$ is 13,000 K for small condensations (Q regions) and is 14,000–17,000 K in A regions. The values are characteristic of upper chromospheric temperatures and transition layer temperatures. For supergranular structures the true T_B is about 10,700 – 10,800 K in A and Q regions, typical of the lower chromosphere. In other words small condensations, which are more compact in A regions, are appreciably hotter than supergranular structures; the latter are practically of the same temperature in both regions. Condensations of radio emission do not form a continuous sequence in the regions examined and all are concentrated around characteristic size of granules and supergranules.

Could the effect observed be due to the time variations of radio emission from the whole area D. To exclude this possibility scans along the same path were repeated without Mercury. These records did not show appreciable fluctuations similar to that of Fig. 1. Moreover we have examined the cross correlation of these fluctuations with those without Mercury; the cross-correlation coefficient never reached 0·05. The fluctuations we consider here cannot therefore, be

connected with possible time variations of the radio emission of the Sun as a whole[4].

Ionisation ledges in the equatorial ionosphere

A CUSP formation on topside ionograms recorded at equatorial latitudes by means of the satellite Alouette I, has been discussed by earlier workers[1, 2]. The cusps are associated with an ionisation ledge lying along the magnetic field line passing through the peaks of the equatorial anomaly.

We here describe observations of cusps associated with echoes reflected from a feature aligned with the field below the anomaly field line and we suggest how the ledge of ionisation in the equatorial topside ionosphere may be formed.

On ISIS-2 ionograms from the dip latitude region 9°N to 7.5°S, recorded at Ahmedabad on October 6, 1972. The ionograms were reduced to electron density profiles by the 'parabolic in log N method'[3].

Figure 1 shows one of the sequence of ionograms exhibiting a cusp, and Fig. 2 shows the corresponding electron density profile. The ledge, which is an enhancement of the electron density over the 'normal' level shown by the dashed line is clearly evident. The horizontal arrow (Fig. 2) indicates the height of maximum percentage deviation of the electron density in the ledge region and the tip of the vertical arrow indicates the height from which the cusp echoes were reflected. The cusp echoes were returned from below the ledge.

Figure 3 shows the heights of constant electron density contours in an altitude against dip latitude diagram. The equatorial anomaly is well developed and the dashed line in the diagram shows the magnetic field line passing through the peaks of the equatorial anomaly. The height of the anomaly field line over the equator is 860 km. The heights at which the maximum percentage deviation of the ledge electron density

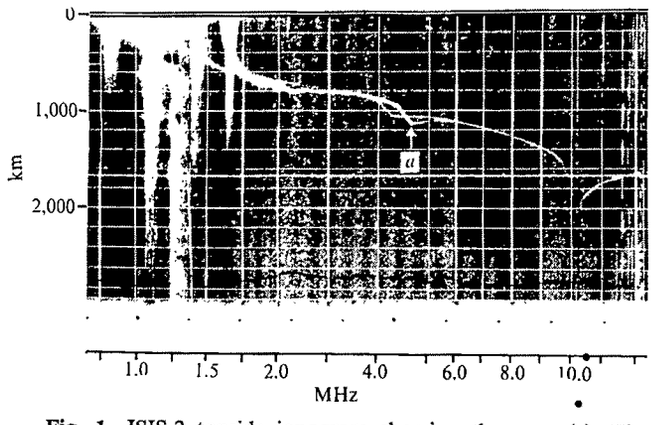

Fig. 1 ISIS-2 topside ionogram showing the cusp (*a*). The x axis is the frequency (MHz), the y axis is the virtual depth (km) below the satellite.

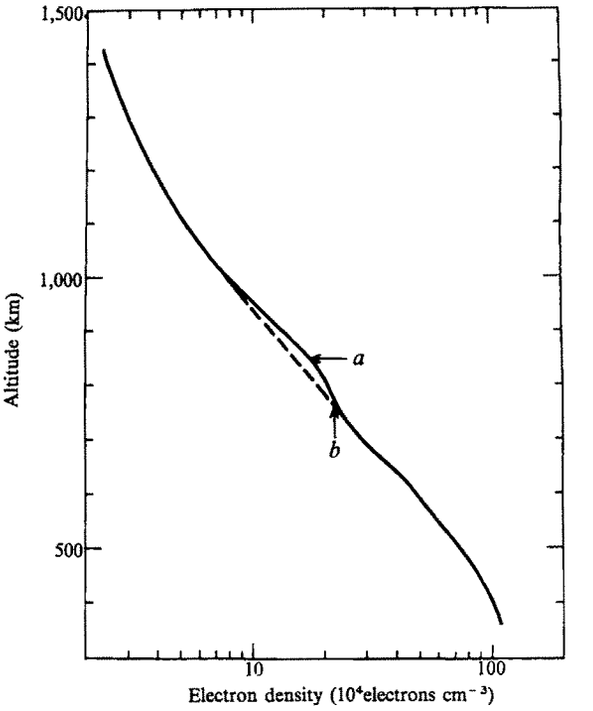

Fig. 2 The electron density profile obtained from the ionogram shown in Fig. 1. recorded October 6, 1972 (UT, 08 h 00 min 32s; LT 1240). Longitude, 70° E; latitude, 7.6° N; dip latitude, —1.42°. *a*, Height of maximum deviation of electron density; *b*, altitude of echoes associated with cusps.

occurred at different dip latitudes are shown by squares in the diagram and they fall on or closely to the anomaly field line. The maximum percentage deviation was observed to increase towards the dip equator, reaching a maximum value of 16%.

The circles in Fig. 3 indicate the heights at which the cusp echoes were reflected. The locus of the 'cusp points' are aligned along a magnetic field line crossing the magnetic equator 775 km above the ground, that is, below the anomaly field line. The ionograms were accurately scaled and the error in evaluating the true height of the cusp points is not more than 15 km. A possible mechanism leading to the formation of a ledge of ionisation such as that observed, can be described.

Recent observations of the neutral densities of molecular

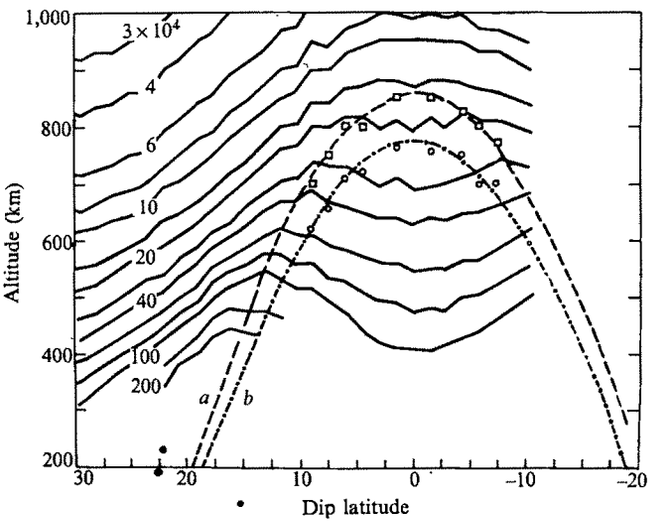

Fig. 3 Latitudinal variation of the height of contours of constant electron density. □, Ledge maxima; ○, heights at which echoes associated with the cusps were reflected. *a*, Locus of anomoly peak; *b*, locus of cusps.

nitrogen and atomic oxygen using a mass spectrometer on the satellite, OGO 6, reveal an equatorial anomaly at an altitude of about 450 km, similar to that in the equatorial ionosphere; density maxima (crests) occur on either side of a minimum (trough) at the magnetic equator. Typical values of the differences between the densities of N_2 and O at the trough from those at the crests, observed at $\pm 20°$ magnetic latitude, are 20% and 10% respectively. It seems likely that the neutral density enhancements will extend above 450 km, along a magnetic field line in a manner similar to the ionisation enhancements, and will merge above the magnetic equator. The neutral temperatures derived from the observed densities show enhancements of 3 to 4% at the neutral density crests.

The existence of enhancements aligned with the field in the neutral density will decrease the diffusion of plasma along the field lines involved. Ionisation in the equatorial ionosphere is lifted vertically during the day by the $\mathbf{E} \times \mathbf{B}$ effect, where $\mathbf{E}$ and $\mathbf{B}$ are the electric and magnetic fields respectively, and diffuses downwards along the magnetic field lines with an ambipolar diffusion coefficient[4]:

$$D_a = [(T_e + T_i)/T_i]\,[7 \times 10^{18}/n(\mathrm{O})]\,[T_n/1{,}000]^{\frac{1}{2}}\ \mathrm{cm^2\,s^{-1}} \quad (1)$$

where T_n, T_i and T_e are the neutral, ion and electron temperatures respectively, and n(O) is the number density of atomic oxygen. The value of D_a increases exponentially with altitude as the neutral density, which is predominantly atomic oxygen in the topside ionosphere, decreases, and can be represented by $D_a = D_0 e^z$ where z is measured in units of the atmospheric scale height H and D_0 is the value of the diffusion coefficient at any known lower level.

The ionisation velocity, V, along the field line, resulting from diffusion in the absence of temperature gradients and winds, is given by[5]

$$-V = (D_a/H)\,[(1/N)\,(\mathrm{d}N/\mathrm{d}s) - (1/2)\sin I] \quad (2)$$

where I is the dip angle and s the distance along the field line measured in units of H and taken positive in the northward direction, so that $-\mathrm{d}z/\mathrm{d}s = \sin I$.

Equation 2 shows that at a given dip angle V is directly proportional to D_a which varies inversely with the density of neutral atomic oxygen (equation 1). Away from the equator neutral density enhancements occur along the ionisation anomaly field line. Along this field line the diffusion coefficient, and therefore the diffusion velocity parallel to the field line, will be decreased by about 10% because of the enhanced O concentration. Any increase in neutral temperature along the same field line will increase the scale height. This further decreases the diffusion velocity. We suggest that these processes will result in the enhancement of the electron density around the field line on which the neutral density is greatest. The field line with which the ionogram cusps are associated may thus occur at the beginning of the sharp rise in the neutral density.

Lightning incidence in Britain and the solar cycle

The existence of a correlation between solar activity and meteorological or climatological parameters seems no longer in doubt and a credible explanation has recently been suggested[1]. It has also been shown that the mean monthly or yearly number of sunspots gives a crude but effective index of the solar activity and that the most marked variation is cyclic with a period of approximately 11 yr.

It has been deduced from lightning-counter records (F. Popolansky's, unpublished) and from analysis of faults caused by lightning in overhead electricity supply systems[2,3] that the mean incidence of lightning (usually expressed as the number of flashes per unit area per year) is proportional to the mean number of annual thunderstorm days recorded by observers, raised to the power 1.9. The data from 40 Meteorological Office observers chosen to be representative of Britain were used to obtain means of the annual number of thunderstorm days for the years 1930 to 1973, and the square of the mean for each year was taken as a rough index of the annual incidence of lightning. The 5-yr running means of both the annual values of this index and the mean annual sunspot numbers are plotted in Fig. 1. In spite of the year-to-year variations in

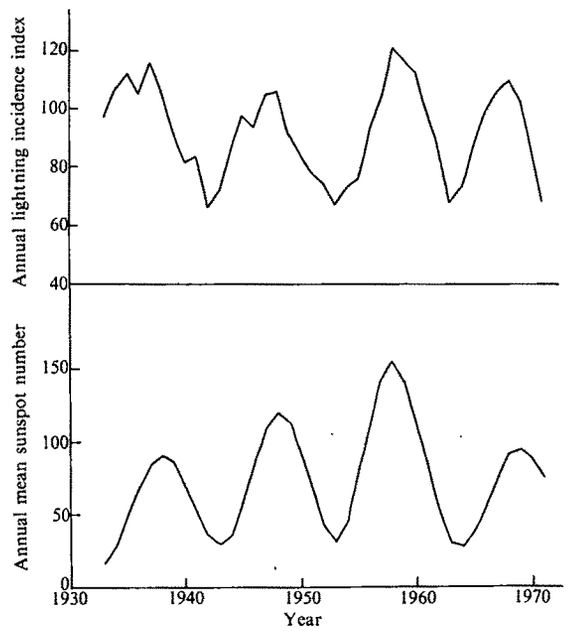

Fig. 1 Annual variation of: *a*, 5-yr running means of lightning incidence; *b*, sunspot number.

the incidence of lightning, there is an underlying cyclic variation with a period of about 11 yr which is in phase with the solar cycle and has an amplitude of $\pm$ 30% of the mean. The correlation obtained between these smoothed data is 0.8, a result of statistical significance despite the smoothing. During the period 1964 to 1972 the trend in faults attributed to lightning on the British electricity distribution network also followed the lightning incidence/sunspot cycles but these fault data are too few to be statistically significant.

The conclusion that the underlying trend in lightning activity is related to the solar cycle is not only of interest to the atmospheric physicist but also to those electricity supply and civil engineers who are concerned with long-term planning of lightning protection. Of more immediate

interest is the fact that mean lightning incidence in Britain reached a minimum in 1973 and, neglecting year-to-year variations, can be expected to reach a peak at the peak of the next solar cycle with a magnitude of about twice the 1973 level.

Major and trace elements in the Allende meteorite

WE have determined major and trace element abundances for seven Ca,Al-rich aggregates, ten melilite chondrules, and an olivine chondrule and two olivine-rich aggregates from the Allende meteorite, a type III carbonaceous chondrite. Major element abundances were determined with the electron microprobe technique described by Reed and Ware[1]. An MS7 spark source mass spectrometer was used for the determination of trace element abundances. The technique used was that described by Taylor[2] but with improved and extended data reduction techniques. The precision is about ±5% for the rare earth elements (REEs) and the accuracy about ±10%, but varies somewhat, being poorer for elements below mass number 105 than for those with higher mass numbers.

The Allende samples can be grouped in various ways using chemical, mineralogical and textural parameters. Our results distinguish four distinct groups, as follows: group I, melilite-rich chondrules; group II, CaAl-rich aggregates with fractionated chondrite-normalised REE abundance patterns; groups III, Ca,Al-rich aggregates with unfractionated chondrite-normalised REE abundance patterns, except for negative Eu and Yb anomalies; group IV, olivine-rich chondrules and aggregates.

The range and average of the elements studied for each group and for the bulk meteorite are given in Table 1. Chondrite-normalised REE abundances of the average for each group and for the bulk meteorite are shown in Fig. 1.

The melilite-rich chondrules in group I are spherical aggregates of melilite, Ti-rich fassaite, spinel and anorthite with a coarsely crystalline igneous texture, and have high Al_2O_3, high CaO and an unfractionated REE pattern averaging 10–15 times chondritic abundances but with a small positive Eu anomaly. In contrast the olivine-rich chondrules and aggregates of group IV have an REE abundance pattern averaging three times that of the chondrites, with possibly a slight positive Ce anomaly and a slight negative Eu anomaly. The major and trace element abundances of these two chemically distinct types of chondrules indicate that the melilite chondrules may represent the initial condensates from a cooling gas of solar composition and the olivine chondrules later low-temperature condensates. (Condensation sequences for a cooling gas of solar composition have been calculated by Lord[3], Larimer[4] and Grossman[5].)

The fine-grained Ca,Al-rich aggregates, composed mainly of spinel, fassaite, melilite and/or grossular, and minor amounts of nepheline and sodalite, can be divided into two groups on the basis of their trace element abundances. Two of the seven examined, classified as group III, have relatively unfractionated REE abundances at about 20 times those of chondrites, but with large negative Eu and Yb anomalies. Even though the chemistry of these aggregates, like that of the melilite chondrules, suggests they would be the first condensate from a cooling gas of solar composition,

The numbers in brackets after the groups are the number of specimens analysed: the figures for the bulk composition are from a compilation by E. Jarosewich (unpublished).

it is apparent from their fine-grained texture and the presence of grossular that these aggregates cooled rapidly, certainly more rapidly than the primeval solar nebula. It would seem therefore that the melilite chondrules and the aggregates of Group III have been subjected to similar high energy events, which vaporised already condensed material, the chondrules cooling from a gas through the liquid state to the solid whereas the aggregates, because of conditions of lower pressure, cooled directly from a gas to a fine-grained solid.

The remaining five Ca,Al-rich aggregates, however, classified as Group II, exhibit remarkable REE abundance patterns. Although the light REE (La-Sm) show similar abundances in groups II and III, group II aggregates have rapidly diminishing abundances of the heavier REEs. Superimposed upon this are a marked negative Eu anomaly and a large positive Yb anomaly. Group II aggregates are also depleted in Y, Zr, Mo and possibly Nb with respect to those of group III. Tanaka and Masuda[6] have described an Allende aggregate with a group II REE pattern. Like the group III Ca,Al-rich aggregates, the aggregates of group II have a fine-grained texture and contain metastable minerals, indicating they cooled rapidly, probably directly from the gas phase to a fine-grained solid.

It is very difficult to produce the fractionated REE abundance patterns of group II either by fractional condensation or evaporation at a suitable temperature range based solely on the boiling points of the REE metals or any of their compounds for which there are sufficient data. For example, even assuming that Eu and Yb exist in the divalent state and are located in different lattice sites to the remaining trivalent REEs, Sm and Dy are not depleted relative to the other REEs yet have much lower boiling points. It is possible that a property of the REEs for which we, as yet, do not have sufficient information might, under certain conditions, give rise to the fractionated REE patterns observed.

An intriguing alternative is that the group II aggregates may contain a component which has had a different history of nucleosynthesis to other matter in the Solar System. The light REEs are produced by an *s* process inside stars whereas the heavy REEs are produced predominantly by the *r* process during supernova explosions. Clayton *et al.*[7] on the basis of oxygen isotope anomalies, have postulated a separate history of nucleosynthesis for some of the Ca, Al-rich material of the Allende meteorite. They found enrichment of ^{16}O in all anhydrous minerals in C2 and C3 meteorites, however, whereas we find depletion of heavy REEs only in group II Allende aggregates, and thus there seems to be no correlation between these two anomalies. Critical examination of our data on isotopic abundances of the REE shows no indication of preferential depletion in *r*-process nuclides, and Gray *et al.*[8] found no evidence of lack of isotopic homogeneity in Rb and Sr execpt for variation in ^{87}Sr abundance produced by radioactive decay of ^{87}Rb.

The differences in minor and trace element distributions evidently reflect differing conditions of genesis of these components. The melilite chondrules seem to represent material segregated at an early high temperature stage; the olivine chondrules and aggregates at a slightly later stage, and the aggregates of groups II and III may represent residual material which condensed after the previous components had segregated from the initial material. The complex pattern of trace element distributions in these Allende components indicates a complex history of formation of this meteorite.

We thank Mrs P. Muir, Mr J. Nelen, Mr M. P. Gorton and Professor A. E. Ringwood for help and advice. This research was supported by the National Aeronautics and Space Administration and the Smithsonian Research Foundation.

Chandler wobble and viscosity in the Earth's core

JEFFREYS[1], and Munk and MacDonald[2], have stated that viscosity of the core cannot account for the observed damping of the Chandler wobble. This statement may be in error.

Jeffreys's statement is based on a simple algebraic error on page 257 of the fourth edition of *The Earth*[1]. He starts from the assumption that there exists, at the core–mantle boundary, an Ekman boundary layer of thickness $(\nu/\omega)^{1/2}$, where ν is the kinematic viscosity and ω the angular velocity of rotation of the earth. If V is the differential velocity between the core and the mantle, the rate of dissipation for unit area is of the order of $\rho V^2 (\nu\omega)^{1/2}$, where ρ is the density. If α is the small angle between the axes of rotation of core and mantle, $V = a\alpha\omega$, where a is the radius of the core. The total rate of dissipation, F, is then

$$F = 4\pi\rho a^4\omega^2\alpha^2(\nu\omega)^{1/2} \quad (1)$$

This is Jeffreys's equation (13) except for the factor 4π and his inadvertent writing of ω^3 instead of ω^2. This error is unfortunately carried into the numerical result on the following line (Jeffreys's equation (14)); the damping time, which is proportional to $1/F$, is consequently too long.

Munk and MacDonald[2] (page 170) proceed in essentially the same way as Jeffreys, except that they write $V = \alpha a \sigma$, substituting the frequency, σ, of the Chandler wobble for ω. The substitution is hard to justify. Munk and MacDonald justify it with Jeffreys and Vicente's[3] demonstration that, to a first approximation, the core remains motionless, which is, however, precisely the reason that Jeffreys[1] adopted $V = \alpha a \omega$.

Returning to Jeffreys' corrected expression (1), and comparing F with the wobble energy, E_w of the mantle:

$$E_w = \frac{1}{2} A_m \frac{(C_m - A_m)}{C_m} \omega^2 \alpha^2 \quad (2)$$

where A_m and C_m are the principal moments of inertia of the mantle. The time, τ, needed to reduce the energy by $1/e$ is

$$\tau = \frac{E_w}{F} = \frac{A_m}{8\pi\rho a^4} \frac{(C_m - A_m)}{C_m} (\nu\omega)^{-\frac{1}{2}} \quad (3)$$

and the time needed to reduce the amplitude in the same ratio is 2τ. Observations indicate that $2\tau \sim 30$ yr. Equation 3 then gives for the kinematic viscosity of the core

$$\nu = 0.026 \text{ cm}^2 \text{ s}^{-1} \quad (4)$$

Leppaluoto[4], using the significant-structure theory of liquids, finds that the dynamic viscosity, $\eta = \nu\rho$, of liquid iron at its melting point and at the pressure of the core–mantle interface (1.4 Mbar) probably lies between 0·1, and 0·5 poise. The density at the top of the core is approximately 10 g cm^{-3}, and the corresponding limits on ν are therefore 0.01 and 0.05 cm^2 s^{-1}, which nicely bracket the value of equation 4, even though Leppaluoto's values should be corrected for the presence in the core of elements other than iron (for example, sulphur), and for temperature, which, at the core–mantle boundary, is unlikely to be precisely the melting temperature of pure iron. Gans[5], using somewhat questionable approximations, suggests $\nu = 0.066$ cm^2 s^{-1} as a typical value of the viscosity of the liquid core at the inner-core boundary.

The third (1952) edition of *The Earth* does not have the ω^3 error[6]. Assuming $\nu = 5 \times 10^7$ cm^2 s^{-1}, Jeffreys consequently found a damping time that was too short and concluded that the viscosity of the core must be less than 10^5 cm^2 s^{-1} to account for the observed damping. He did not conclude at that time that viscous damping of the Chandler wobble is impossible, as indeed it does not seem to be.

Montmorillonite in surface detritus

QUANTITATIVELY, clay minerals are usually the most important components of those fractions of deep-sea sediments which are smaller than 2 μm. There are specific patterns in the distributions of the principal groups of clay minerals in both deep-sea sediments[1] and in aeolian dusts from the overlying marine atmosphere[2], which have been used to evaluate the origin of the clays. It is considered[1–3] that the clay minerals kaolinite, illite and chlorite are largely detrital in origin and are transported to the oceans from the continents.

Less is known, however, about the origin of montmorillonite. Deep-sea sediments of some regions, for example, the South Pacific, show extensive evidence that montmorillonite has formed from the *in situ* alteration of volcanic debris on the ocean floor[1], that is the montmorillonite is authigenic. A similar explanation has been proposed for the origin of montmorillonite in Indian Ocean deep-sea sediments[1], where this mineral makes up approximately 41% of the total clays smaller than 2μm. There is, however, speculation about the origin of montmorillonite in deep-sea sediments from the South Atlantic, where it comprises approximately 26% of the total clays smaller than 2 μm (ref. 1). It is believed[1–3] that either the montmorillonite or the parent volcanic material is transported to the region by aeolian and river mechanisms or that the mineral is derived from volcanic material from the Mid-Atlantic Ridge region. These theories are based on observations of the distribution of montmorillonite in deep-sea sediments; there is little information available on its concentration in marine detritus from the World Ocean.

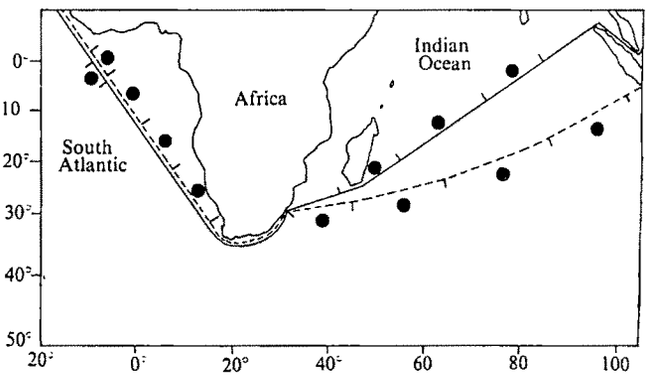

Fig. 1 Partial track of the MV Cyclops. Solid line, UK–Japan run; broken line, Japan–UK run. Detritus samples were collected over the intervals indicated by the lines perpendicular to the track; ●, central positions of sampling sites.

Here, we present preliminary data on the relative concentrations of montmorillonite in 'open-ocean' surface water samples (0–5 m) from the South Atlantic and Indian Oceans. Collections were made during March and July, 1972 on board MV Cyclops by pumping water from a position in the ship's bows (which minimised contamination from the ship's sides) through plastic tubing. The particulate matter was separated by continuous centrifuging. The centrifuge bowl was lined with plastic and after each collection the liners were removed, placed in plastic bags and stored in a deep freeze. The detritus was later removed from the liners and dried at about 40° C, and representative samples taken. A fraction of the samples smaller than 2 μm was separated, treated with hydrogen peroxide to remove organic matter, and the clay minerals were determined by X-ray diffraction. The ship's track and the sampling positions are shown in Fig. 1 and the average montmorillonite concentrations in the detritus are listed in Table 1 together with those of the underlying deep-sea sediments.

On average, the concentration of montmorillonite is similar in detritus samples from both the South Atlantic and Indian Oceans, and constitutes approximately 14% of the total clays smaller than 2 μm. This is considerably less montmorillonite than is present in the underlying deep-sea sediments. Furthermore, the relative distributions of montmorillonite vary between the detritus and deep-sea sediments of the two regions; in the South Atlantic there is about one and a half times as much montmorillonite in the sediments as in the detritus, and in the Indian Ocean about three times as much in the sediments.

There are a number of explanations for the deficiency of montmorillonite in the detritus relative to the sediments. For example, other clay mineral species, and/or volcanic

Table 1 Average concentration of montmorillonite*

South Atlantic Ocean	
Detritus	~14%
Deep sea sediments[2]	~26%
Indian Ocean	
Detritus	~14%
Deep sea sediments[1]	~41%

* The concentrations of montmorillonite are given as a percentage of the four clay minerals montmorillonite, illite, chlorite and kaolinite in the fraction of the detritus and sediments smaller than 2μm.

ash, could be transported to the surface of the ocean and could subsequently undergo modification to form montmorillonite both in the water column and at the sediment surface. Alternatively, montmorillonite could be formed from the *in situ* modification of locally derived volcanic debris at the sediment surface. Whatever processes are operative, however, it may be concluded from the present results that only about half of the montmorillonite in South Atlantic deep-sea sediments, and only about a third of that in Indian Ocean sediments, have a continental detrital origin.

We thank the Blue Funnel Line for permission to make collections from their ships; the Master, officers and crew of the MV Cyclops; A. J. Woodward for his help in the collection of samples; and the Natural Environment Research Council for financial support.

Revised continental fit of Australia and Antarctica

I HAVE already presented a morphological reconstruction of the continental fragments of Gondwanaland in the south-western Pacific[1]. The reassembly was based on the computer-generated fits of Australia and Antarctica[2,3] (which match the 1,000-fathom and 500-fathom isobaths). The method used in each case[2,3] is a 'least squares' geometric fit of the selected isobath. Another fit has recently been proposed[4], for this fit an instantaneous rotation pole is determined from fracture zones, at 10.8° N, 32.2° E, but the Australia–Antarctica fit is based on a 'least squares' geometric pole at 6° S, 40.5° E. I suggest that all of these fits may be in error by about 250 km, as present-day isobaths only define poorly the predrift continental edges.

A better method of making continental reassemblies is to 'reverse' seafloor spreading, using a mapped pattern of magnetic lineations and fracture zones. Such a pattern is fairly well defined between Australia and Antarctica[5,6]. Weissel and Hayes[6] show several stages of drift (see their Fig. 13), but in the initial step they have accepted the computer fits[2,3] as the constraint. They therefore delineate a westward bend in fracture zones south of Australia, amounting to some 250 km (see their Fig. 2). Hayes and Ringis[7] attempted a regional continental reconstruction but erroneously implied that the Australia–Antarctica fit has been "rather precisely determined" using only the reversal of the magnetic patterns, whereas Weissel and Hayes[5,6], in fact, used the computer fit[2,3]. They note that the South Tasman Rise overlaps the Iselin Plateau, presuming that both are continual crust, and then suggest that relative movement of West and East Antarctica occurred during drift.

In the light of these problems and inconsistencies, I have revised my original reconstruction[1] (Fig. 1). The fit was made using a 1:15 million scale Lambert's Equal Area Azimuthal projection, centred at 160° E, 60° S (near Macquarie Island). Continental boundaries were initially defined at the 2,000-m isobath, and fracture zones plotted from ref. 6, except that each fracture zone was projected straight towards the Australian coast. Australia was then

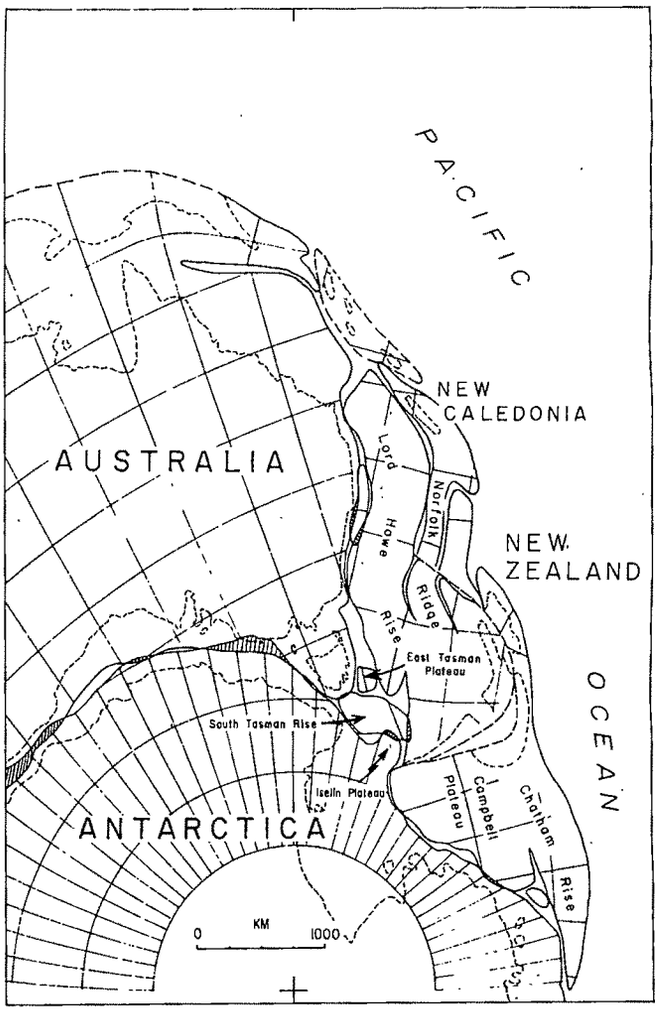

Fig. 1 Reconstuction of continental fragments in the south-western Pacific. Continental outlines and 2,000-m isobaths (smoothed) shown, taken from Lambert's Equal Area Azimuthal projection, centred at 160° E, 60° S. Present latitude and longitude lines (5 °spacing) shown for reference. Hatching denotes overlap.

fitted to Antarctica by reversal of motion along the intervening fracture zones. This operation places Australia some 250 km west (relatively) of its position in earlier computer fits[2-4] and allows the continental South Tasman Rise[8] to fit neatly between Tasmania and the Iselin Plateau (Fig. 1).

The fit was checked by rotating contiguous points to their present positions using a 50-cm stereographic net, and it was found that rotation about a pole at 10.8° N, 32.2° E

(determined from fracture zones in ref. 4) gave results consistent with the fit proposed here, and significantly different from the least squares geometric fits. The shape of mutually opposed coasts on the Lambert's Equal Area projection were compared with their computer-drawn equivalents by enlarging the latter optically to a scale of 1:15 million. No significant distortion was found.

The Campbell Plateau was fitted against Antarctica as before[1] and the Tasman Sea closed by a 23° rotation of the Lord Howe Rise about a rotation centre at 145° E, 15° S. This is broadly consistent with the Tasman Sea magnetic pattern but implies that the orientation of fracture zones, particularly in the north, is different from that of Hayes and Ringis[7]. This suggests that their interpretation may be in error in this region. A 5° grid (present coordinates) is superimposed on the fragments in the reconstruction (Fig. 1). This shows that neither the Campbell Plateau nor the Lord Howe Rise have been deformed to achieve the fit. The only significant deformation required is along the Alpine Fault Zone through New Zealand.

The modified fit (Figs 1 and 2) still has one major overlap, where the bulge of the Antarctic 2,000-m isobath overlaps Australia. A similar mismatch (though placed further west) was noted by Sproll and Dietz[2], who suggested that either the Antarctic bathymetry was substantially in error in this area, or that postrift volcanics or sediments form the bulge. A detailed compilation of available oil-company exploration data from the south-eastern Australian continental margin shows, however, that with the fit suggested here, this bulge largely overlaps an Upper Mesozoic and Cainozoic sedimentary sequence in the Otway Basin of south-eastern Australia[9]. These are typical rift-fill sediments (refs 9, 10, and K. A. Richards, and B. M. Hopkins, ECAFE Symposium, Canberra, 1969) which represent an unusually wide development of the continental margin in this area. On Fig. 2, I have delineated the 3,000-m isopach of Upper Mesozoic and Cainozoic sediments along the Australian margin, selecting this line as more representative of the predrift margin. The correspondence of this isopach with the Antarctic 'bulge' is quite clear.

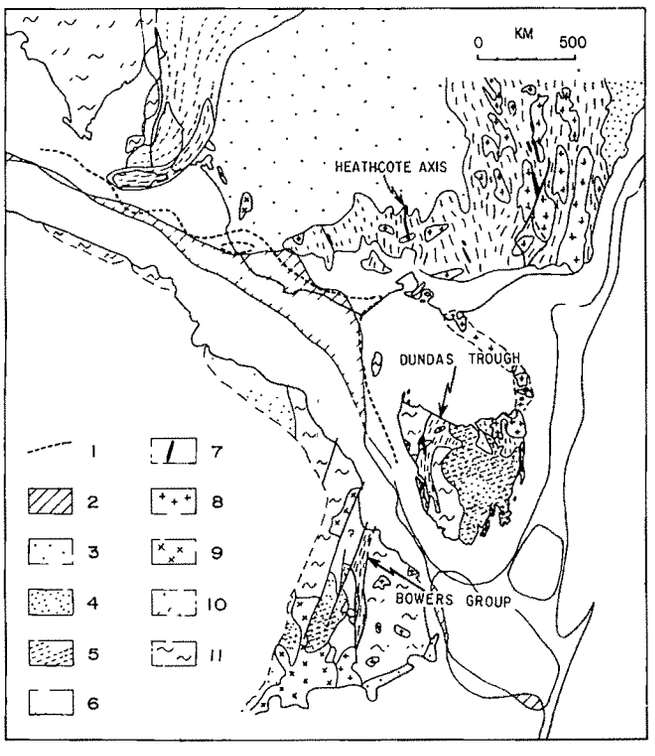

Fig. 2 Detailed fit of south-eastern Australia and Antarctica, showing major geological elements. 1, 3,000-m isopach of Upper Mesozoic Cainozoic sediments of south-eastern Australia; 2, overlap of 2,000-m isobaths; 3, Cainozoic sedimentary cover; 4, Upper Palaeozoic and Mesozoic basins (essentially undeformed sediments); 5, areas of Jurassic dolerite intrusions; 6, Palaeozoic of Tasman Orogenic Zone; 7, ultramafic masses; 8, Silurian-Devonian granites; 9, Cambrian–Ordovician granites; 10, late Proterozoic sediments of the Adelaide Geosyncline (moderately folded); 11, exposed Precambrian "basement". Some major faults are also shown by heavier solid lines. Data taken from refs 11 (Australia) and 12 (Antarctica).

The outlined fit (Figs 1 and 2) is therefore preferred to computer fits based on present isobaths[2,3] and points to the obvious need to establish the geological status of lines of fit before using computer techniques. Isopachs of marginal sediments are probably a more realistic definition of prerift continental shapes. The fit also eliminates the source of several 'problems' in the region. For example, the South Tasman Rise is incorporated without any movement of West Antarctica.

Figure 2 also shows the major geological elements of mainland Australia, Tasmania and Antarctica[11,12]. No certain correlations can be made yet. One speculative correlation, however, is that of the Dundas Trough (Cambrian sediments, ophiolites and Andean-type calc-alkaline volcanics[13]) with the Heathcote Axis (Cambrian greenstones and calc-alkaline volcanics[14]) and Bowers Group (Cambro–Ordovician sediments[15,16]). This suggestion offers a chance to correlate narrow units, without depending on vague lithological similarities, but needs further evaluation.

There has been some discussion of alternative reassemblies and argument for and against major transcurrent movements active during the Palaeozoic and Mesozoic[17–20]. These articles do not allow for any possible error in the computer fits[2,3] and generally make very vague and generalised lithological correlations to support their conclusions. Many of the supposed difficulties in regional correlations using earlier fits[2,3] diminish considerably if the revised fit presented here is valid. The occurrence of Precambrian basement rocks in Tasmania also suggests that the island is uplifted relative to Victoria and Antarctica, probably as a result of Cainozoic seafloor spreading and therefore a relatively deeper erosion level is observed at present in Tasmania[9].

The present knowledge of the regional geology, seems to provide little to support unequivocally hypotheses involving major transcurrent movements[17,19,20].

I thank R. D. Beattie for helpful comments.

Archaean tectonics

THERE is compelling evidence that Archaean convective motions were very different in scale from the motions which we associate with modern plate tectonic phenomena. The ancient motions resulted in a distinctive surface expression. Many lines of evidence suggest that the Earth is cooling by heat and mass transfer which is reflected in magmatic phenomena at or near the surface. Evidence of convective mixing in all regions of the deep Earth is accumulating. Today, the major sites of mass and energy transfer are at the ocean ridges where new crust is formed. This motion towards the surface is balanced by the return of crustal material at the subduction zones. There are few sites of crust formation. They are all elongated, with linear dimensions comparable with the circumference of the Earth, and they are widely spread.

Geological maps of the crust of more than 3×10^9 yr ago indicate a totally different tectonic-magmatic situation. Such regions are well documented from southern Africa and Greenland[1]. The sedimentary and igneous rock types in these regions have, in general, modern counterparts, and they provide evidence of the existence of an extensive hydrosphere. The rocks of the granite family, however, dominate 80–90% of the geologic maps and there are no significant areas of ophiolitic rocks; no analogues of the modern ocean crust[2]. Metamorphic rocks of the granulite facies are very common and are often associated with anorthosite complexes[3]. Metamorphic events reflect steep thermal gradients. Extensive linear features are rare and volcanic–sedimentary basins involve complex mixtures of volcanic types from ryholites and andesites to basalts and komatiites. This is not a modern situation.

A model for the early crust must take account of three concepts. Runcorn[4] has summarised evidence which indicates that convective motions have been quantised through time. The evidence from age distribution patterns is compelling. Elder[5] has indicated how the thermal structure of the Earth is appropriate to a body cooling from the surface and in a state of vigorous convection. The models involve a rather thin surface region with a steep thermal gradient followed by a deep, essentially isothermal region. Where the gradient changes rapidly, there is a layer of high thermal turbulence with large fluctuations of temperature (a possible low velocity or melting region). With time, this region will sink into the cooling body and the amplitude of fluctuations will decay. Finally, Fyfe and Leonardos[6] point out that basalt will not continuously penetrate a fusible granitic layer; fusion of the granite, will form a viscous low density layer, and this will turn off injection or encapsulate the heavier magma. I use the term encapsulate in the sense in which it is used in the ceramic or metallurgical industries to describe the situation in which a heavy material is protected from the environment by a lighter, viscous, glassy layer.

The Archaean model proposed here is in part a result of an attempt to explain the map and synthesis proposed for the Rhodesian craton[7] which is similar to many cratonic regions of a comparable age. Before any quantum jump

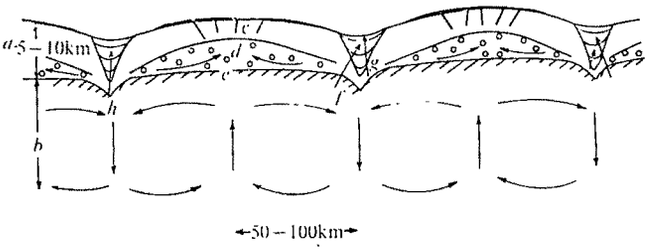

Fig. 1 Model of convective motion in the early crust and upper mantle, *a*, granitic crust; *b*, low velocity zone of upper matle; *c*, region of basaltic penetration of the crust; *d*, granitic domes; *e*, granulites and anorthosites; *f*, basalts; *g*, rhyolites; *h*, andesites.

in the convective pattern[4], the dynamic structure could be as shown in Fig. 1. A continuous, thin, highly radioactive, easily fusible granitic layer, 5–10 km thick (Fig. 1*a*), overlies a high-level melting zone in the upper mantle (Fig. 1*b*). In the melting zone partial melting occurs on a large scale, and various products of melting result from a high level of thermal turbulence. Convection cells in the mantle have a short wavelength pattern (about 100 km) as is implied by the separation of basins in Rhodesia[7]. Basalt penetration of the crust (Fig. 1*c*) is sporadic and is terminated by crustal fusion and the formation of granitic domes (Fig. 1*d*). Basalt flow is concentrated beneath the encapsulating acid layer. The basalt tends to underplate the acid crust and fractionates to produce anorthosite complexes which themselves will be associated with granulites, the crustal fusion residue (Fig. 1*e*). Above regions of return flow where the crust is thinned, volcanic rocks may be injected; basalts, rhyolites, or, where mixing occurs, andesites (Fig. 1*f*, *g*, *h*). During periods of maximum thermal turbulence and high partial fusion, the ultramafic komatiites may erupt.

The situation after the convective pattern changes might represent that pertaining only for a short time before the change. The quantum jumps are considered to be towards larger cells (compare with ref. 4). In the model of early patterns, heat–mass transfer in the upper layers involves a two-storey motion, with basic magmas adding heat to the acid layer which itself overturns by magmatic processes. Erratic convective motion could lead to thrusting of the mini-continents, which would produce the type of tectonics frequently observed when basement rocks are exposed.

It is proposed here that modern ophiolitic plate tectonics began only after the thermal regime of the acid crust allowed stable thickening to the point where granitic materials did not cover most of the earth. This idea does not conflict with palaeomagnetic results discussed by Piper *et al.*[8] and perhaps provides the "supplement to plate theory of orogenesis" discussed in their work. It could be predicted that future convective patterns will lead to a further thickening of acid materials and a more extensive covering the basaltic crust.

Electrons and the emission of soot from flames

AN increasing body of evidence suggests that soot formation is associated with ionisation in flames and may be controlled electrically. Work in which sooting flames are subjected to large electric fields[1–3] shows that all soot particles are charged (at least in the presence of an applied field) and can therefore be manipulated by fields. This applies not only to fully formed particles but also to their growth and burning up in flames. Thus by applying fields so as to remove particles rapidly from the zone in which they are formed, their size as well as the total yield is greatly reduced. The former is ascribed to the decreasing residence times and the latter to the removal of surface on which growth can occur. Conversely, very large particles can be produced by holding them stationary against the gas flow by means of a field and thereby increasing their residence times. Also, any appreciable field intensity removes the charged nuclei on which carbon particles tend to grow[3].

Many practical systems are not amenable to the application of large electric fields and a great many research projects have concerned themselves with the effect of additives (refs 4–8 and E. M. Bulewicz, D. G. Evans, and P. J. Padley, personal communication). The most effective additives have generally proved to be substances which have low ionisation potentials or form particles of low work functions. Thus the alkali metals, when introduced to the extent of parts per million, alter the 'structure' of carbon black and the effectiveness of the additive in breaking long chains is in the inverse order of its ionisation potential. Although the order of effectiveness within each group of elements is determined by the ionisation potential, this does not apply across groups, the alkaline earths, for example, differing from the alkali metals, barium additives which produce $BaOH^+$ as the positive ion being the most effective. Also, the same additive can produce suppression of soot formation, or its promotion, depending on the amount and the position in which it is introduced. Where the position of addition is not localised, the pattern is that small amounts of additive produce promotion whilst large amounts produce suppression with a crossover point of zero effect in between. When the additive is introduced locally—on a wire, say—insertion at the base of the flame produces suppression; introduction higher up results in an increase of soot produced[6].

Chemical—as an alternative to electrical— effects have been considered responsible for some of these observations[5]. Since electronic structure is inevitably related to chemistry, the issue is most likely to be resolved by the application of electric fields. Different groups, however, have used either additives, or applied fields—not both simultaneously. We now propose a hypothesis based on free electrons and then test it by the combination of the two techniques. Although the results bear out the hypothesis and, furthermore, offer a novel practical method for controlling soot emission, this does not, of course, constitute a proof that chemical effects could not also be important.

Most of this work has been carried out in diffusion flames —in which the reactants are initially separate the maximum temperature and the main reaction zone occurring close to the stoichiometric contour. This is also close to the surface along which ionisation will peak, being a strong function of temperature. It is not, however, the region of carbon formation, since conditions for pyrolysis are most favourable on the fuel side, where there is a lack of oxygen. Thus if ionisation is to play a major part in soot formation, the diffusion coefficient of the charge carrier must be a most important parameter. Of the particles involved, it is the electron that has by far the largest diffusion coefficient and it is known that the negative charge carrier in the high temperature zones of flames is an electron[2]. We therefore suppose, as an initial hypothesis, that the effect of additives is entirely due to the free electrons which they produce. We shall then attempt to account for all previous experimental observations in terms of such a hypothesis and, if that is successful, design some further crucial experiments.

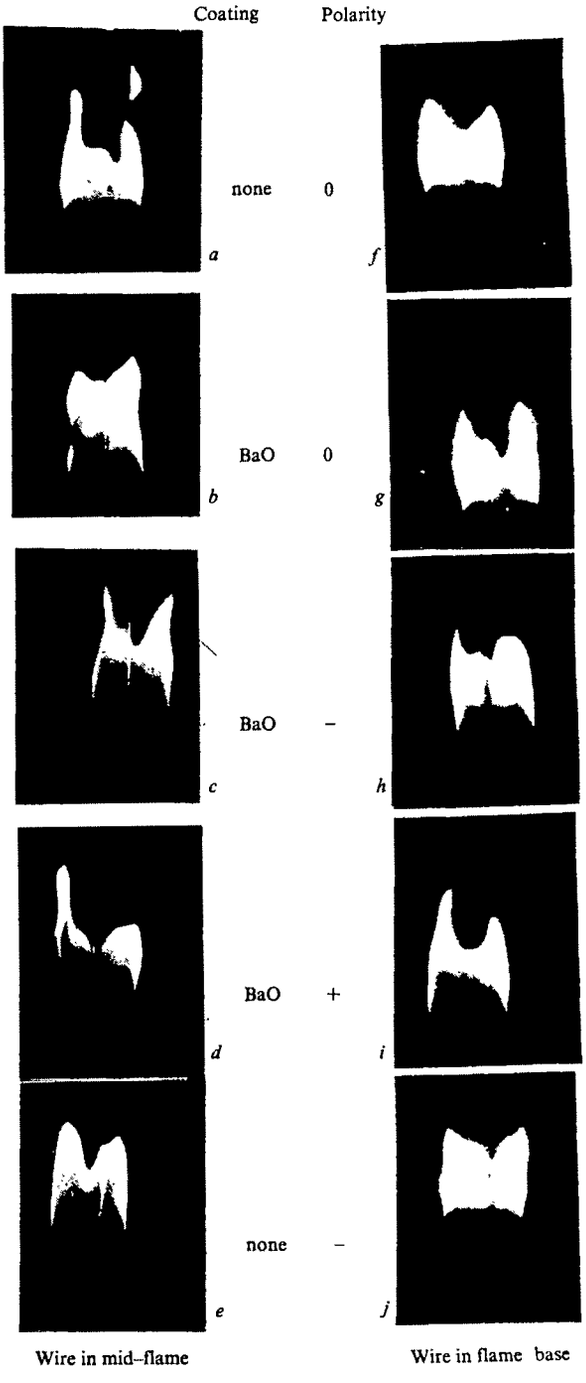

Fig. 1 Effect of coating and polarity on soot formation above wires.

Although the chief role of an influx of additional electrons into the pyrolysis zone is likely to be that of neutralising positive charges, this can have two diametrically opposed consequences. Where all or most of the particles[1–3], or

chains of particles, are positively charged, neutralisation of positive charges at their extremities would stop them repelling one another and thereby remove the obstacle to agglomeration. Agglomerates of appreciable size are much less likely to burn away during their subsequent passage through the high temperature zones in the presence of oxygen. When only a fraction of the chains is charged, on the other hand, agglomeration occurs by dipole action, the rate reaching a maximum when the fraction charged is a half. For smaller proportions of charged particles, electrons will therefore decrease agglomeration rates.

This proposition accords extremely well with the observed facts. Large electron concentrations will eventually always inhibit agglomeration and thereby suppress soot formation. Electron concentrations insufficient to neutralise a very large proportion of particles under conditions where the majority of particles is charged will act mostly as a 'glue' in encouraging small particles to aggregate and thereby increase the mass of soot escaping.

The dependence on the mobility of the positive ion also falls into place, although the role attributed to it is diametrically opposed to what has been supposed hitherto. In terms of the above hypothesis, the positive ion acts chiefly through recombining with the electrons it meets away from the high temperature zone (it is of course much more likely to encounter an electron than a carbon particle). The larger the ion the smaller its excursion.

Although this tentative hypothesis thus accounts for all the experimental observations, a much more direct test would be one in which the additive would be discouraged from migrating by being held on a wire at a relatively low temperature, whilst the charges emanating from it could be controlled by an electric potential applied to the wire.

Nichrome wires coated with barium oxide and uncoated wires of diameter 0.2 mm were inserted at various heights into diffusion flames of propane diluted with argon, burning with air. The flames consisted of single, approximately flat, faces, which were contrived very simply by attaching a 'fish-tail' nozzle to the fuel burner tube and blowing off the second flame face by an adjacent argon stream emerging from a similar nozzle. The results are shown in the photographs of Fig. 1 and the current–voltage characteristics of Fig. 2.

The results are in exact accord with the predictions of the hypothesis, in that it is the electron which produces effects characteristic of the additive. At heights where the additive promotes soot formation (Fig. 1*b* as compared with Fig. 1*a*) application of a negative potential, encouraging the emission of electrons, greatly increases the effect (Fig. 1*c*) and the application of a sufficient positive potential prevents it altogether (Fig. 1*d*). It transpired from the current–voltage characteristics that positive potentials not only prevented electron emission but led to the emission of positive ions (Fig. 2) and some ionic wind effects came into evidence at higher currents. The absence of soot formation in the case of positive ion emission casts doubt on previous suppositions that positive inorganic ions themselves act as nuclei; they do of course mop up electrons.

We tried, unsuccessfully, to explain these effects in terms of what is already known about the effects of electric fields on carbon formation. According to this, the negatively charged wire would be expected to collect the positively charged carbon particles—and this is indeed precisely what happens in the case of the uncoated wire (Fig. 1*e*)—rather than to increase soot formation. Once a layer of carbon is built up on the wire, of course, electron emission sets in.

Figure 1(*f–j*) illustrates the effects observed when wires are inserted into zones in which suppression is produced by the additive in the absence of an applied potential (Fig. 1*g*). Although these are the reverse of the pattern of Fig. 1*a–e* they also can be summarised by the observation that the behaviour associated with additives is manifested by free electrons. It is accentuated when the applied field promotes electron emission and tends to reverse when electron emission is prevented by positive polarity of the support.

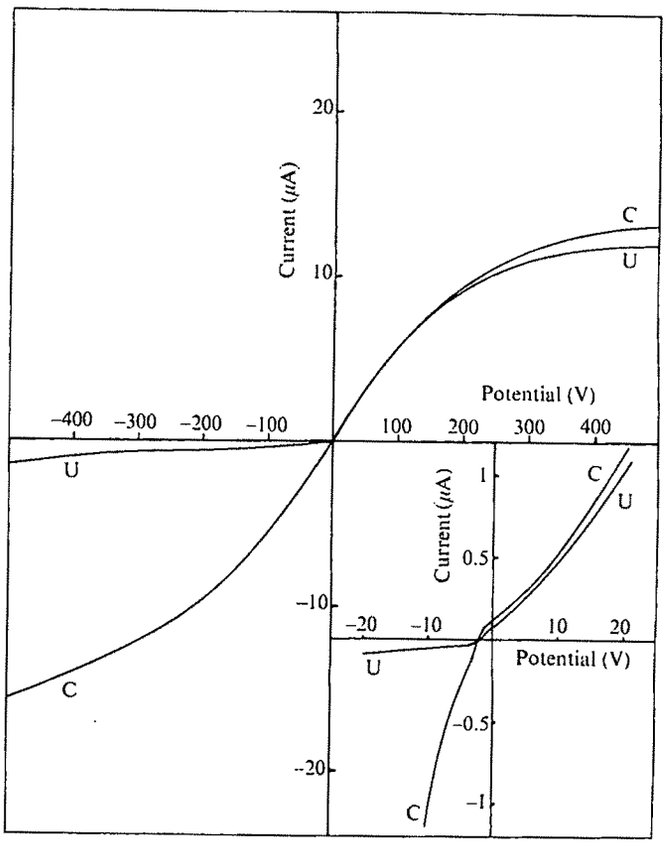

Fig. 2 Current/potential characteristics of the wire with respect to the burner, of coated (C) and uncoated (U) wires in mid-flame.

We do not suggest that the entire subject of sooting in flames can be accounted for in terms of free electrons and we think it very likely that the underlying chemical processes retain the importance that has been attributed to them. But it does seem possible to account for the behaviour of ionising additives entirely in terms of the electrons they produce as regards both suppression and promotion, the effect of the amount of additive, the site of its introduction and the effect of ion size.

What is probably much more important is that we can produce all the observed effects by controlling the emission of free charges electrically, using coated surfaces maintained hot by the flame, and connected to a source of electrical potential—without introducing additives into the fuel and, thereafter, into the atmosphere by way of exhaust gases. The power that would be involved in injecting electrons in this manner would, of course, be quite small, 1 mA being sufficient to provide 6×10^{15} particles s^{-1}.

Radicals in irradiated ethyl iodide and related compounds

IN studies of the radiolysis of various alkyl halides, particular attention has been focused on a multiline electron spin resonance (ESR) spectrum obtained from ethyl iodide at 77 K (ref. 1). Despite the use of a wide range of isotopically enriched materials, however, there has been no satisfactory interpretation of these complex ESR spectra and this remains one of the unsolved problems of ESR spectroscopy[2].

The spectrum for normal CH_3CH_2I comprises sets of 'parallel' and 'perpendicular' type features covering a total range of about 1,000 gauss which seem, in the outer regions of the spectra, to comprise sextets with $a \approx 22$ gauss. These are centred close to the free-spin g value (see Figures in ref. 1).

Studies of other alkyl halides[3–5], indicate that the most likely candidates are the α– or β–iodo alkyl radicals (Fig. 1, I and II). Radical I is, however, expected to exhibit a very marked g-value variation which would lead to considerable spectral asymmetry,

I II

Fig. 1

with strong features in the region of low-field, and even if these radicals were librating or rotating the resulting g_{av} value would be $>> 2.0023$. This is not observed, and indeed, the spectra are completely different from that obtained from irradiated α–iodo acetamide, which we assign to $HCI(CONH_2)$ radicals (G. W. Neilson, and S. P. Mishra, unpublished results).

Again, the β–iodo radical, II, is expected to have a far larger hyperfine coupling to ^{127}I than is possible for the ethyl iodide radical, and the α–proton coupling should give rise to a triplet having $a \leqslant 20$ gauss. (Coupling to the two β–protons should be small.)

Thus I and II can be firmly rejected. The radical $CH_3CH_2 - - - I^-$ is, however, a likely candidate. Methyl bromide in a methyl cyanide matrix gives a species $CH_3 - - - Br^-$, which has the normal magnetic properties for methyl radicals, but with each feature split into a pair of quartets by hyperfine coupling to ^{79}Br and ^{81}Br (ref. 6). We have extended this work to include methyl iodide, which again gave a spectrum characteristic of methyl, with a weak hyperfine coupling to iodine[7] (Table 1).

We find that the spectra published by Willard *et al.*[1], and ourselves for normal CH_3CH_2I can be quite satisfactorily analysed on this hypothesis, using the parameters given in Table 1. In particular, the 22-gauss sextets have their $\pm 5/2$ components broadened, as is usually the case for ethyl radicals in rigid media, and therefore could be mistaken for quartets (1 : 3 : 3 : 1), thus closely resembling the features for $CH_3CD_2 - - - I^-$, as noted by Willard *et al.*[1].

Comparable species were not obtained from methyl iodide or from solutions of ethyl iodide in CD_3OD. A very similar species, $(Me)_3C\cdot - - - I^-$, was, however, obtained from t-butyliodide (Table 1).

Table 1 ESR parameters for $CH_3CH_2 - - - I^-$ and related anions

Medium	Radical	Hyperfine coupling (gauss) *, † ^1H	^{127}I
CD_3OD‡	$CH_3 - - - I^-$	21 (∥)78	(⊥)56
C_2H_5I	$CH_3CH_2 - - - I^-$	22 (∥)168	(⊥)126
Me_3CI	$Me_3C - - - I^-$	22 (∥)> 53.5	(⊥)53.5

*, 1 gauss = 10^{-4} T;
†, all g values close to 2.0023;
‡, ref. 6.

We conclude that the process involved is

$$RI + e^- \rightarrow R\cdot - - - I^-$$

in which the radical, R·, has its normal planar geometry, but, under favourable circumstances, exhibits a very weak charge-transfer interaction with iodide. We suggest that the occurrence of this interaction, and its magnitude, is governed primarily by the crystal structure of the host compound and therefore by the mobility of the alkyl radical. The results for CD_3OD solution show that the interaction is lost when iodide can be solvated, even at 77 K.

Lyoluminescence of trehalose dihydrate

LYOLUMINESCENCE of trehalose.$2H_2O$ in water has been observed over a wide range of radiation doses. It has been possible to cover linearly the range from 10 rad up to 150 krad. With some samples the lower limit was 100 mrad.

The emission of light when irradiated saccharides are dissolved in water has been described[1,2]. Saccharides were chosen because of their good solubility in water and because they are quite good soft tissue equivalent materials. Free radicals which formed during irradiation of the solid probably cause the light emission when they are set free to react in solution[3].

There is evidence from our experiments that the diffusion controlled reactions involved in the process of light emission are of the type:

$$R^{\cdot} + R^{\cdot} \rightarrow R\text{–}R \quad (1)$$

$$R^{\cdot} + O_2 \rightarrow RO_2^{\cdot} \quad (2)$$

$$2RO_2^{\cdot} \rightarrow R\text{–}R + (O_2)_2^{*} \quad (3)$$

This is based on the several observations.

(1) The emission spectrum of all saccharides (for example, trehalose.$2H_2O$, glucose, mannose) has a maximum at approximately 4,900 Å as determined by interference filters. This coincides with the absorption peaks of the S→T transition of $(O_2)_2$ associate[4].

(2) When irradiated saccharides are annealed at different temperatures, they tend to exhibit more lyoluminescence. This is a result of the temperature-assisted diffusion of O_2 during annealing.

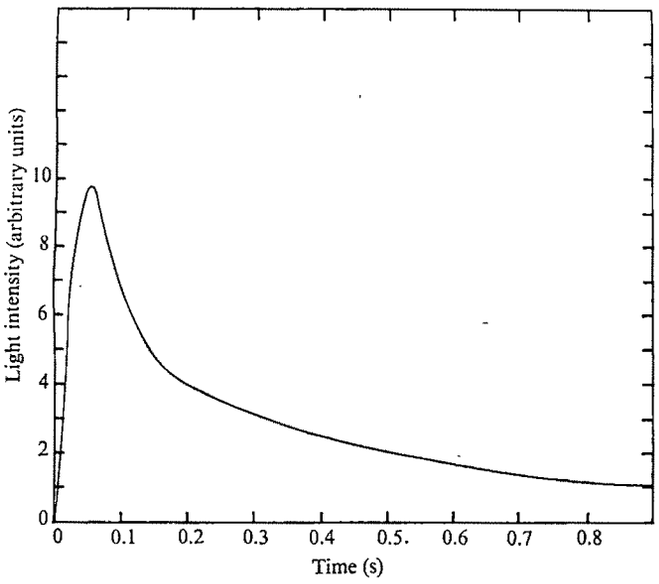

Fig. 1 Lyoluminescence decay curve of trehalose.$2H_2O$ in water.

(3) The addition of $\approx 10^{-4}$ M concentration of Cu^+, Cu^{2+}, $Mn\,O_4^-$ and $Fe(CN)^{3-}$ quenches the light to 31%, 14%, 4% and 1.5%, respectively, of the value for pure water. Addition of fluorescein has no effect, whereas water saturated with O_2 enhances the light emission. The quenching effect of these ions is because of the tendency of radicals to react preferentially with them instead of with oxygen. The failure of fluorescein to enhance the light, suggests that no energy transfer occurs between the produced R–R and fluorescein molecules.

(4) Reaction (2) has to compete with reaction (1). At higher concentrations of radicals, that is, at high doses, reaction (1) becomes more frequent as the distance between radicals decreases. This explains the saturation and the decrease in the light yield over 150 krad, which is common for all saccharides (Fig. 3). The actual saturation level in solid saccharides, as determined by ESR, is over 100 Mrad (ref. 5).

When luminol solution was used instead of water the enhancement of light emission was a million times in the case of glucose and twenty times for trehalose.$2H_2O$. The light emission accompanying the oxidation of luminol strongly suggests that $RO_2^{\cdot}$, with its oxidising properties, is involved in the process.

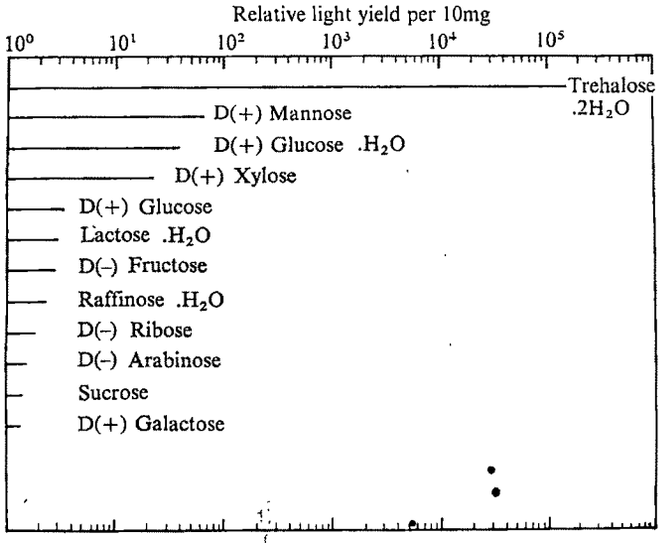

Fig. 2 Lyoluminescence response of saccharides to radiation. All given the same dose (67 krad) using a ^{60}Co γ source.

Figure 1 shows the lyoluminescence decay curve of trehalose .$2H_2O$ in water. The light which can be seen easily with the naked eye, was integrated for a period of 3 s, which adequately covers the light output. The relative lyoluminescent sensitivity of various saccharides is presented in Figure 2.

The relationship between the radiation dose (using a ^{60}Co γ source) and the integrated light intensity is shown in Figure 3. The curve is linear between 100 mrad and 150 krad. The lower limit is mostly controlled by the dark current of the photomultiplier tube and can be improved by one order of magnitude if a cooled tube is used. It also depends on the lyoluminescence response of trehalose which varies for samples of different origin.

The lyoluminescence stability of trehalose.$2H_2O$ after irradiation was revealed by the isothermal annealing after

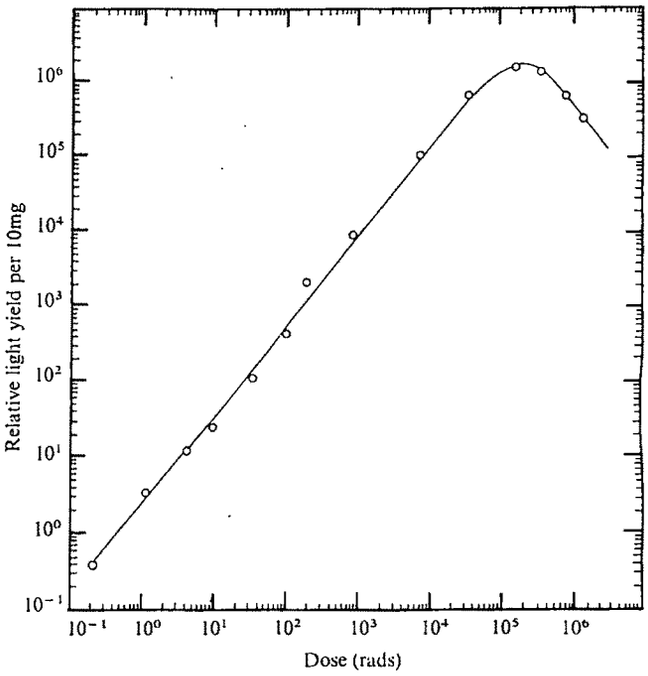

Fig. 3 Light yield against radiation dose for trehalose.$2H_2O$ dissolved in water.

irradiation. A sample heated to 80° C for 2 h showed no change in the light output and heating to 60° C for 60 h caused a decrease of only 18%. These results are consistent with the measurements of Löfroth *et al.*[6], who found that irradiated trehalose.$2H_2O$ loses only 10% of its ESR signal after storage for six months.

We thank Professor J. H. Fremlin for guidance and advice. This work was supported by the Science Research Council.

BIOLOGICAL SCIENCES

SV40 nucleoprotein complex activity unwinds superhelical turns in SV40 DNA

THE replication of closed circular superhelical DNA of simian virus 40 (SV40) has been shown to proceed through replicative intermediates that are composed of newly synthesised linear polynucleotide chains hydrogen bonded to closed circular template (parental) strands[1–3]. To replicate these molecules in a semiconservative fashion a swivel, about the phosphodiester backbone of the template strand of DNA, required during polynucleotide chain propagation[2,3]. Such a swivel could be obtained by a nuclease which introduces a single-stranded break in the template strand, thereby allowing free rotation about the phosphodiester bond opposite the nick and relaxing the superhelical turns in the DNA molecule. This type of single-stranded break must, however, be transient and rapidly ligased closed in the cell because breaks in the template strands of replicative intermediates have not been detected[1–3]. Alternatively, an activity has been described in *E. coli*[4,5] and mouse cells[6], that can relax superhelical turns in closed circular DNAs without introducing either single or double-stranded chain scissions in the DNA product of this reaction. This 'untwisting activity' is also a potential candidate for the swivel required during SV40 DNA replication.

The replicative intermediates of SV40 DNA have most often been characterised[1,2,7] after lysing SV40-infected cells with sodium dodecyl sulfate (SDS) in the presence of 1 M NaCl[8]. This results in the isolation of viral DNA molecules that contain little or no protein associated with the DNA[7]. When polyoma[9] or SV40-infected[10,11] cells are lysed instead with the nonionic detergent Triton X-100 in the presence of 0.2 M NaCl, all the viral DNA is recovered in a rapidly sedimenting nucleoprotein complex (44–53S). This complex contains both mature viral DNA as well as the SV40 replicative intermediates[10,13], associated with histone-like proteins and at least two of the viral coat proeins coded for by the *ts*B8 and *ts*B11 loci of SV40[11,12]. The complex containing replicative intermediates sediments faster than that composed solely of mature viral DNA[10,13].

Here we report that the SV40 nucleoprotein complex has associated with it an untwisting activity that reduces the number of superhelical turns in exogenously added SV40 DNA. The underwound product of this reaction remains closed and circular as detected in the ethidum bromide (EtBr)–caesium chloride (CsCl) dye-density gradient. This activity has been shown to be associated with the nucleoprotein complex that contains either mature or replicative intermediates of viral DNA.

SV40-infected African Green Monkey Kidney cells were labelled with ^{3}H-thymidine for 20 h, starting 16 h post-infection[7]. The SV40 nucleoprotein complex was isolated as described in Fig. 1. After concentrating the preparation and dialysis, the complex was incubated at 37°C for 2 h in the presence or absence of exogenous purified closed circular superhelical (Form I) SV40 DNA[7]. At the end of this incubation period, ^{32}P-labelled Form I SV40 DNA was added (at 0°C) to the sample incubated in the absence of exogenous SV40 DNA. Each of these reaction mixtures was then analysed in an EtBr-CsCl equilibrium gradient to determine the amount of Form I and II DNAs present in each sample and to monitor the superhelical density of the endogenous DNA (^{3}H-labelled) in the nucleoprotein complex and exogenously added ^{32}P-labelled DNA.

The results of the EtBr-CsCl gradients are presented in Fig. 1. Two conclusions can be drawn from these data: First, incubation at 37°C for 2 h of 50S complex alone or this complex with exogenously added Form I SV40 DNA resulted in no detectable endonuclease activity that generated relaxed (Form II or III) SV40 DNA molecules (Table I) under these assay conditions. When the 50S nucleoprotein complex was incubated with ^{32}P-labelled exogenous SV40 Form I DNA, however, the superhelical density of this DNA was decreased as seen by a shift of the ^{32}P-labelled viral DNA to a heavier density position in dye-density gradients (Fig. 1*b*). The superhelical density of Form I DNA in the complex (endogenous; ^{3}H-labelled) may also show a small reduction in the number of superhelical turns (Fig. 1*a*, *b*).

To determine if this untwisting activity was preferentially associated with the nucleoprotein complex containing mature DNA or replicating intermedates, the experiment described above was repeated. A second neutral sucrose gradient was used to separate the faster sedimenting component of the nucleoprotein complex that contains mainly replicating DNA from the complex containing mostly mature viral DNA. The untwisting activity was found to be associated with both species of this complex.

These experiments demonstrate the presence of an untwisting activity, associated with 50S nucleoprotein complex, that could act as a swivel during replication of

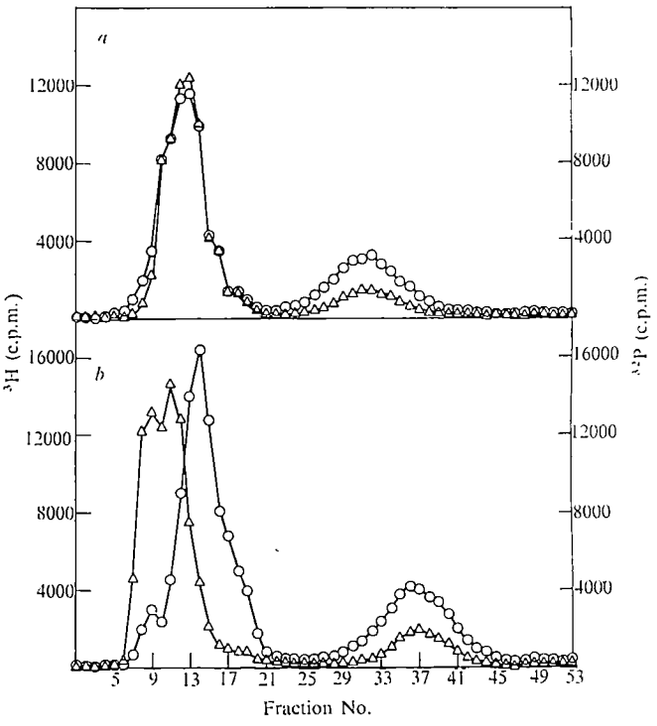

Fig. 1 EtBr-CsCl equilibrium gradients of SV40 DNA incubated with the SV40 nucleoprotein complex. SV40-infected AGMK cells were labelled with ^{3}H-thymidine 16–36 h after infections. The cells were lysed as described previously and the 50S complex was isolated from a sucrose gradient (ref. 9 and A. S., R. Hancock, and A. J. L., unpublished). The complex was then concentrated (5–8 fold) by dialysis against glycerol followed by dialysis against 10 mM Tris buffer (*p*H 7.4), 0.2 M NaCl, 4 mM EDTA and 1 mM β-mercaptoethanol. The ^{3}H-labelled (thymidine) nucleoprotein complex was incubated at 37°C for 2 h with or without exogenously added ^{32}P-labelled purified Form I SV40 DNA (ref. 7). The reaction mixture contained 0.5 μg Form I viral DNA (1.5×10^5 c.p.m. μg^{-1}), 10 mM Tris buffer (*p*H 7.9), 0.1 m NaCl, 2 mM EDTA. The reaction was stopped by adding 1 M NaCl and 1.598 g ml^{-1} of CsCl ($\eta = 1.3900$). 100 μg ml^{-1} of EtBr was added (final concentration) and this mixture (6 ml total) was spun to equilibrium at 32,000 r.p.m. for 90 h in a fixed angle 50 rotor. Samples were collected and counted as described previously[7]. ○, ^{3}H c.p.m. endogenous complex SV40 DNA; △, ^{32}P c.p.m. exogenously added SV40 DNA.

Table 1 Test for nuclease activity in the 50S complex

Procedure	Endogenous DNA Form I	Endogenous DNA Form II	Exogenous DNA Form I	Exogenous DNA Form II
No incubation	90%	10%	76%	24%
Incubation: 2 h at 37°C (50S complex alone)	88%	12%	—	—
Incubation: 2 h 37°C (50S complex plus exogenous DNA)	94%	6%	72%	28%

The experimental details are presented in the legend to Fig. 1. The percentage of Form I and II DNA observed after each incubation produce was calculated from the experimental points in Fig. 1.

superhelical SV40 DNA. The untwisting activity cosediments with the 50S complex upon repeated centrifugation, and is not found sedimenting at the 50S position of a sucrose gradient when uninfected cells are lysed under similar conditions, but it is not clear whether this activity is associated with nucleoprotein complex *in vivo*. Experiments are in progress to characterise conditions where the untwisting activity will act as efficiently upon endogenous viral DNA in the nucleoprotein complex as on exogenously added purified Form I DNA. When such conditions are determined, the nucleoprotein complexes containing replicating viral DNA would then become useful templates for an *in vitro* DNA replication system.

Enzymatic aziridine synthesis from β aminoalcohols—a new example of endogenous carcinogen formation

BETA aminoalcohols are not only used as drugs, such as ephedrine, chloramphenicol or pronethalol, but also occur naturally in animals and man, as adrenaline and noradrenaline, for example. It would be interesting to know whether these β aminoalcohols can be metabolised to aziridines, a class of carcinogenic compounds. Howe[1] described the carcinogenicity of pronethalol (I) and supposed that the aziridine (II) could be the ultimate carcinogen (Fig. 1).

In vitro formation of aziridines from β aminoalcohols only occurs through a less stable intermediate, for example by the sulphate ester in the Wenker synthesis[2]. On the other hand, the enzymatic formation of sulphate esters is catalysed by various sulphotransferases and requires phosphoadenosinephosphosulphate (PAPS) as a sulphate donor[3]. For practical purposes PAPS can be substituted by a mixture of ATP and SO_4^{2-}, which is transformed partially into PAPS by enzymes, contained in the supernatant fraction of liver homogenates[4]. It should be noted, however, that the carcinogenic 2-acetylaminofluorene is also metabolised through a sulphate ester to the ultimate carcinogen[5]. We supposed that the hydroxyl group of β aminoalcohols also could react enzymatically in special conditions to form O sulphates. These sulphates can then be transformed into aziridines in a slightly alkaline medium. To confirm this hypothesis we investigated the enzymatic formation of 1, 2-dimethyl-2-phenylaziridine[6] (III) from the β aminoalcohol[6] (IV), an isomer of ephedrine (Fig. 1):

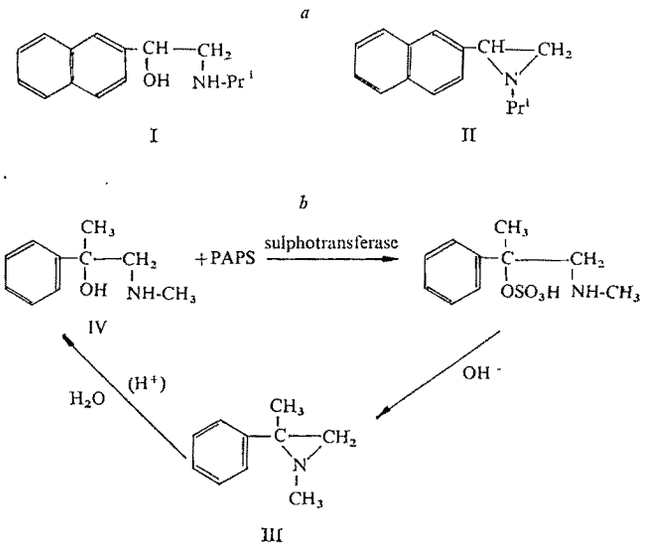

Fig. 1 *a*, Pronethalol (I) and its aziridine (II); *b*, enzymatic formation of 1, 2-dimethyl, 2-phenylaziridine from the β aminoalcohol.

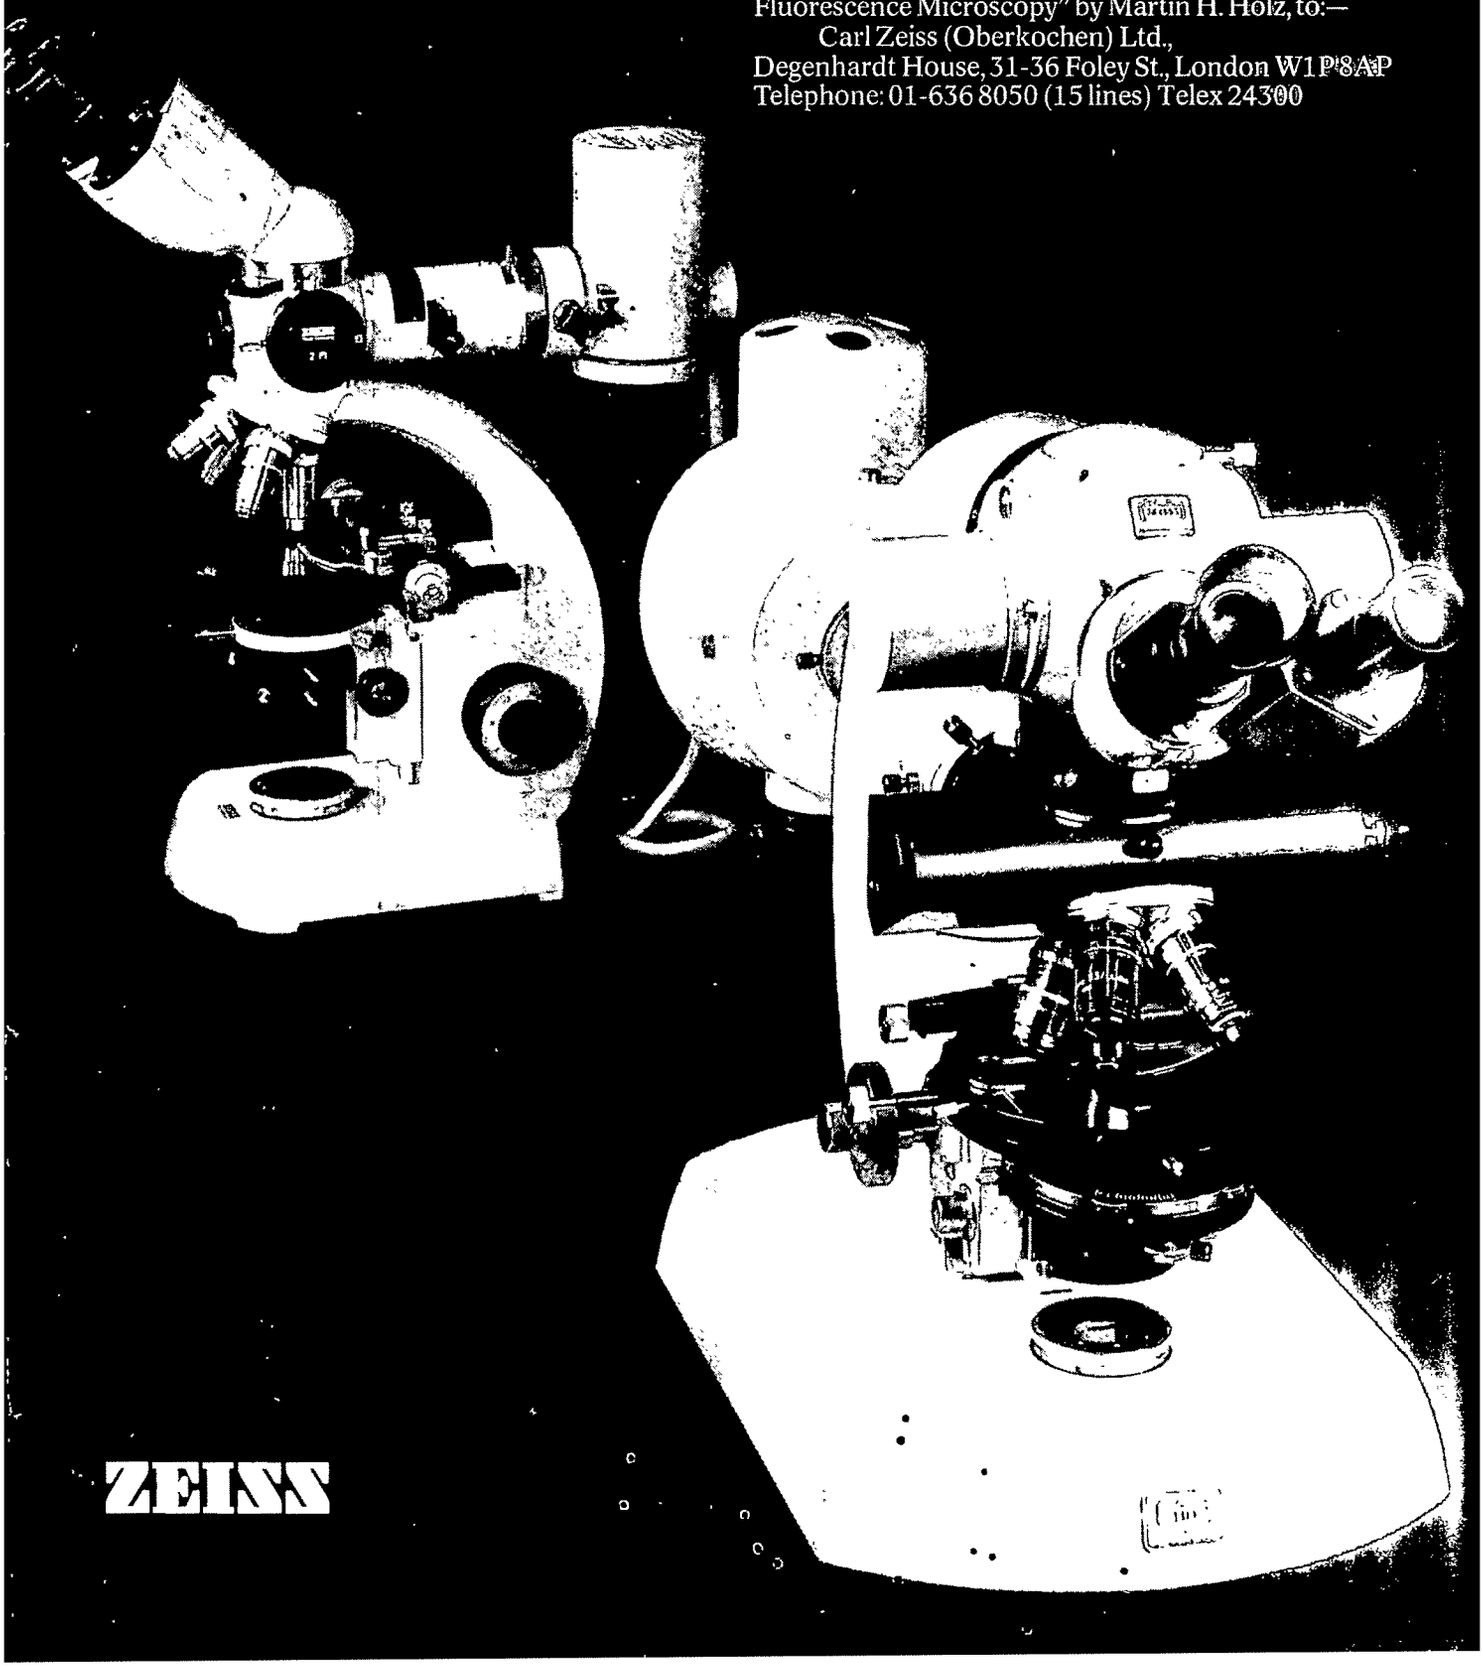
A liver homogenate of a female Hauben rat (20% in 0.1 M potassium phosphate buffer, *p*H 7) was prepared by means of a Potter homogeniser and centrifuged at 100,000*g* for 1 h. To 5 ml of the supernatant, 75 μmol **IV**, dissolved in 0.05 ml ethanol, 50 μmol ATP, 50 μmol K_2SO_4 and 50 μmol $MgCl_2$ were added. After 2.5 h incubation at 37° C the reaction was terminated by the addition of 10 ml of ethanol and the precipitate removed by centrifugation. The supernatant was adjusted to approximately *p*H 8 by 1N NaOH and incubated at 37° C for 1 h. After evaporating to 5 ml under reduced pressure, the alkaline solution was extracted with ether. Basic compounds were separated from the ether solution by extraction with 2N H_2SO_4. The acid solution was alkalised immediately to avoid opening the ring of the aziridine formed. Repeated extraction with ether and evaporation to about 0.5 ml yielded a concentrate, which was investigated by means of TLC on silica gel. The solvent systems used were ethyl acetate–ammonia–methanol (85 : 5 : 10) and benzene–acetone (1 : 1), respectively.

For detecting aziridines, the colour reaction of 4-(4-nitrobenzyl-)pyridine perchlorate (NBP-ClO_4) with alkylating agents[7] was modified. The plate was sprayed with 0.5% NBP-ClO_4 in 1, 2-dimethoxyethane, incubated at 100° C for 30 min and, after cooling, sprayed with 25% aqueous ammonia. The aziridine (III) appeared blue with R_f values of 0.80 and 0.32, respectively, identical with those of authentic samples in both systems. After standing overnight in 2N H_2SO_4, **III** could not be detected in the extract, indicating ring-opening to **IV**. When SO_4^{2-} and ATP were not added to the reaction mixture, aziridine (III) was not formed. We therefore suppose that the aziridine is formed enzymatically from the β aminoalcohol according to the pathway shown in Fig. 1.

These investigations were made from the point of view that aziridines could be synthesised enzymatically not only from various drugs, but also from biogenic β aminoalcohols. This

Fluorescence Microscopy

Every kind of fluorescence microscopy can be carried out with Zeiss equipment.



The new IVF Epi-condenser, fitted to a Zeiss standard or WL series microscope (as shown left) gives a versatile and efficient instrument for all kinds of reflected-light fluorescence work. A special low-priced microscope for routine FITC-induced immuno-fluorescence is also available.

The Zeiss Universal Research Microscope (shown right) offers the ultimate in versatility, including the ability to combine fluorescence work with many other advanced techniques.

We can also offer a new incident-light fluorescence illuminator for any model of the celebrated Zeiss Photomicroscope.

Intragenic regulation of the synthesis of ΦX174 gene *A* proteins

ONLY one phage gene, *A*, has been shown to be necessary for the replication of ΦX174 double-stranded replicative form (RF) DNA[1–3]. The host genes required have yet to be fully determined although one host mutation, *rep*$^-$$_3$, prevents progeny RF synthesis[4]. Dissection of the characteristics of gene *A* has shown that it is (*a*) *cis* acting[5]; (*b*) necessary for the detection of a *cis*-related viral strand specific discontinuity in the parental RF[6,7]; (*c*) the region of the genome which contains the origin of DNA replication[8], and (*d*) a gene from which two proteins, A and A′ (molecular weights 35,000 and 60-65,000, respectively) are synthesised[9,10].

A model for the synthesis of two proteins from one gene is shown in Fig. 1. The synthesis of the smaller protein, A, is initiated internal to gene *A*. Amber mutants mapping from N14 to R7 synthesise only the A molecule, while amber mutants mapping from H90 to S29 do not synthesise either molecule[9]. The tryptic peptides of A′ have been shown to include the tryptic peptides of A in addition to unshared peptides[10].

While trying to understand how two proteins could be synthesised from one gene, we noticed that more of the smaller molecule, A, was synthesised than the larger A′. If a single mRNA served as a template for both proteins of gene *A*, a simple explanation for this observation could be that A′ is translated only from the new mRNA while A is synthesised from old mRNA. This model would predict that synthesis of A′ but not A would be prevented by preventing phage mRNA synthesis.

Preliminary experiments with cells irradiated with ultraviolet light before infection (to eliminate host protein synthesis[11,12]) indicated that A′ synthesis was selectively prevented when rifampicin of 200 μg ml^{-1} was added various times after infection (1, 5, 10 and 15 min). To verify that this effect was associated with gene *A* function, DNA replication experiments were planned. Therefore, the rifampicin effect was then examined in mitomycin C-pre-

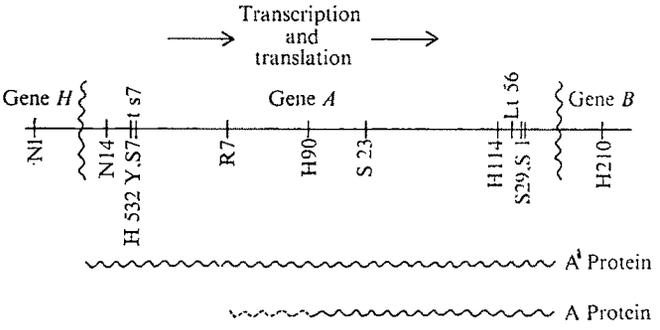

Fig. 1 A model representing synthesis of two proteins from gene *A* of ΦX174. The presumed internal initiator would be between the R7 and H90 positions. Amber *A* mutants N14, S7, H532y and R7 synthesise a stable A molecule while amber *A* mutants H90, S23, H114, S29, and S1 do not synthesise stable A or A′ molecules. Lt 56 and t's-7 are temperature-sensitive gene *A* mutants. The transcriptional and translational directions were derived from previous studies[25–28]. The map of gene *A* was constructed by Marie N. Hayashi.

treated cells (to eliminate host DNA synthesis[2]) using two hosts: *E. coli* HF4704 Rif^r, a mutant resistant to rifampicin in RNA polymerase, and *E. coli* HF4704, a rifampicin-sensitive host. Figure 2*a* shows the effect of adding 200 μg ml^{-1} of rifampicin on ^{3}H-uridine incorporation with mitomycin C-pretreated, ΦX174-infected HF4704 15 min after infection. Figure 2*b* illustrates the same with the rifampicin-resistant host, HF4704 Rif^r. Rifampicin selectively inhibits RNA synthesis in HF4704 cells but not in HF4704 Rif^r cells.

The same protocol was used for labelling ΦX174-specific proteins. Rifampicin (200 μg ml^{-1}) was added 15 min after infection and ^{3}H-lysine was added 1 min later. The infection was allowed to proceed for 15 min and then the protein was isolated and run on sodium dodecyl sulphate (SDS) polyacrylamide gels[11]. Control cultures without rifampicin were labelled with ^{14}C-lysine from 16 to 30 min after infection (with no mitomycin C pretreatment of cells, phage protein is primarily synthesised 15 min after infection (E. Linney, unpublished observation)). Figure 3*a* shows the gel patterns of protein from the infected rifampicin-resistant host. The patterns with or without rifampicin are identical. Figure 3*b* illustrates that with the rifampicin sensitive host A′ is clearly not synthesised when rifampicin is added. All the other phage proteins, previously identified by this laboratory[9,11], are synthesised.

If A is translated from old mRNA, the ratio of A/A′ synthesised might be expected to increase as the infection proceeds. Table 1 summarises results which illustrate this point. *E. coli* HF4704 was preirradiated with ultraviolet light to eliminate host protein synthesis. Cells were then infected with an amber mutant, N11, in the lysis gene *E*. Protein was labelled with ^{3}H-lysine from 0–10, 10–20 and 30–40 min after infection. The protein was isolated and separated on SDS polyacrylamide gels[9,11]. The ratio of A/A′ was calculated from their regions in the gels. In addition, a 0–10 min labelled culture was washed and chased 10–30 min after infection with cold lysine. Similarly, a 10–20 min culture was washed and chased 20–40 min after infection with cold lysine. The results in Table 1 support the view that more A is synthesised than A′ as the infection proceeds. Additionally the chase data support the view that A′ does not chase into the smaller protein A.

Because of the many conflicting reports on the molecular weight of gene *A* products[9,11,13–15], this effect of rifampicin on the synthesis of A′ was examined to see whether it correlated with gene *A* function. To examine this, mitomycin C-pretreated HF4704 cells were infected in the pre-

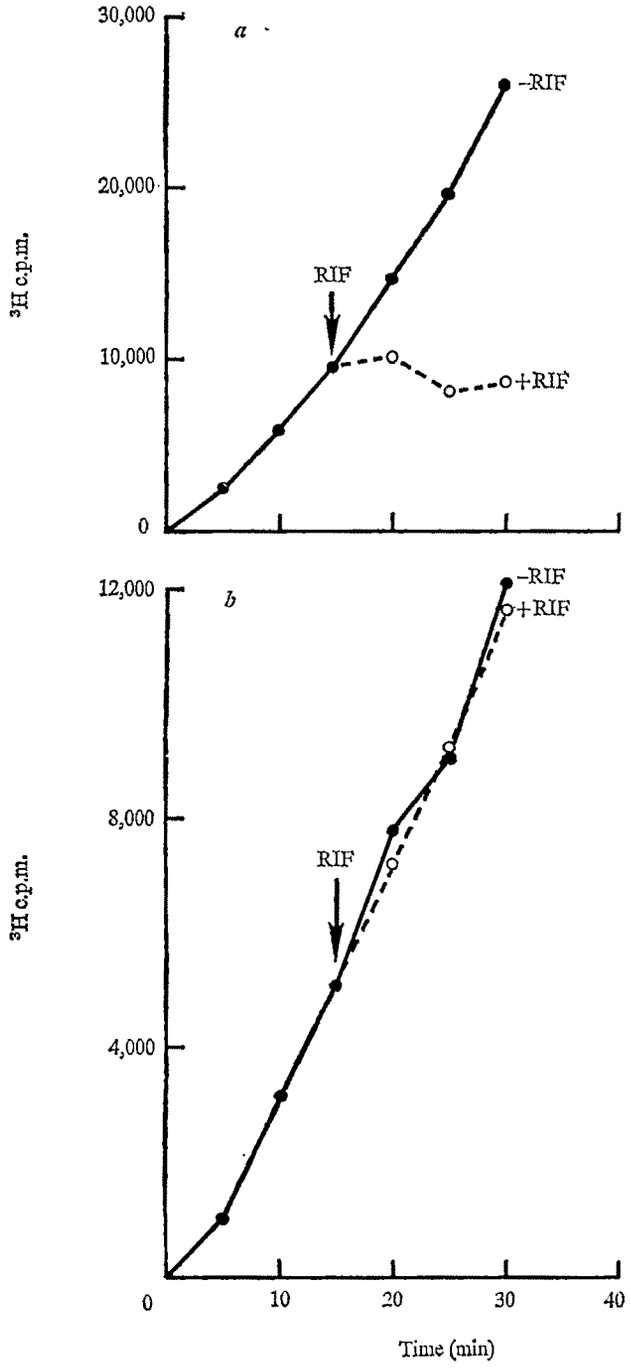

Fig. 2 Incorporation of ^{3}H-uridine into mitomycin C-pretreated, ΦX174-infected cells. *E. coli* HF4704 Rif^r is a spontaneuos mutant of *E. coli* HF4704 selected on rifampicin plates by Marie N. Hayashi. It was found to be rifampicin-resistant in RNA poly erase. HFC and HFB medium have been described previously[11]. Cells were pretreated with mitomycin C at 37° C at a cell concentration of 5×10^8 ml^{-1} in HFC for 30 min with no agitation[2]. Cells were then sedimented and washed once in cold HFB. Phages were adsorbed for 5 min in HFB at a cell concentration of 5×10^9 ml^{-1} at 37° C before starting the infection by diluting ten-fold with HFC. RNA was labelled by adding 20 μCi ml^{-1} ^{3}H-uridine (New England Nuclear Corp., 26 Ci mmol^{-1}) to cultures containing 2 μg ml^{-1} uridine. Fractions (200 μl) were taken for incorporation experiments, precipitated with trichloroacelic acid (TCA) and collected on Whatman GF/C filters for scintillation counting. *a*, Host cell, HF4704; no rifampicin (●—●) 200 μg ml^{-1} rifampicin added 15 min after infection (O- - -O). *b*, Host cell rifampicin-resistant, HF4704 Rif^r; no rifampicin (●—●); 200 μg ml^{-1} rifampicin added 15 min after infection (O- - -O).

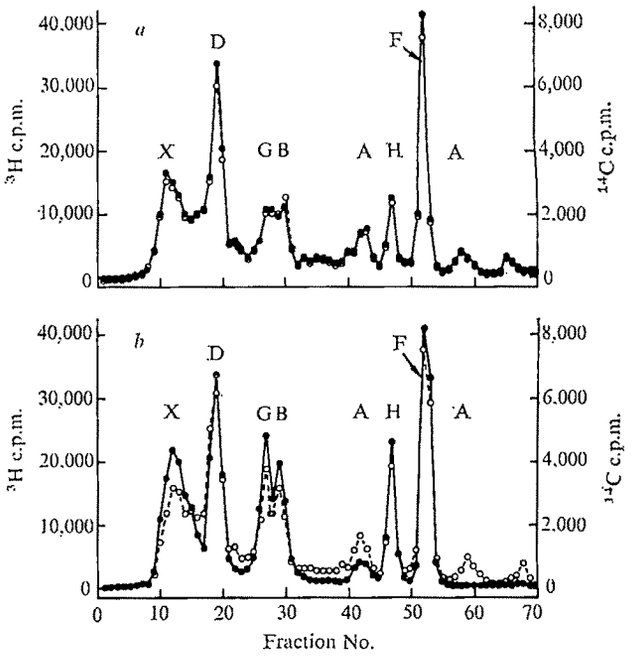

Fig. 3 SDS polyacrylamide gel of ^{3}H and ^{14}C-lysine of ΦX174 total protein from mitomycin C-pretreated cells labelled 16-30 min after infection. Decreasing molecular weight is to the left. The letters represent the gene products previously identified in this laboratory[9,11]. The electrophoresis methods have been described previously[9]. For labelling protein 20 μg ml^{-1} of ^{3}H-lysine (Amersham-Searle, 5.3 6 mmol^{-1}) was added at the given time or ^{14}C-lysine (Amersham-Searle, 342 MCi mmol^{-1}) at an equivalent lysine concentration. *a*, Protein from ΦX174-infected HF4704 Rif^r: 200 μg ml^{-1} rifampicin, 15 min after infection, ^{3}H-lysine, 16-30 min after infection (●—●); no rifampicin, ^{14}C-lysine 16-30 min after infection (O- - -O). *b*, Protein from ΦX174-infected HF4704: 200 μg ml^{-1} rifampicin 15 min after infection (——); ^{3}H-lysine, 16-30 min after infection (●—●); no rifampicin, ^{14}C-lysine, 16-30 min after infection (O- - -O).

sence of 200 μg ml^{-1} chloramphenicol to allow parental RF synthesis[1,16] and mRNA synthesis (unpublished observations of M.H.) but to inhibit protein synthesis. After 10 min of infection the chloramphenicol was washed out in the presence and in the absence of 200 μg ml^{-1} of rifampicin. After washing, the infection was allowed to proceed in the presence or absence of 200 μg ml^{-1} of rifampicin, respectively. Thus, the rifampicin culture would have to rely on old mRNA for gene *A* function. Figure 4 illustrates ^{3}H-thymidine incorporation under these conditions. In the presence of chloramphenicol for 30 min, DNA replication was inhibited while if the chloramphenicol was removed in the absence of rifampicin DNA replication proceeded. If chloramphenicol was replaced with rifampicin, DNA replication remains inhibited.

Thus, phage DNA replication is prevented when it is made dependent on old phage mRNA. That this effect is related to the absence of A′ synthesis and not the absence of a necessary newly synthesised host protein is suggested by previous findings that in cells preirradiated with ultraviolet light to eliminate host protein synthesis, phage DNA replication occurs[11].

The results indicate that A′ is necessary for gene *A* function. The tight coupling between translation and transcription could be responsible for the *cis* effect of gene *A*. Since both A and A′ have been shown to bind tightly to DNA cellulose columns[9], if A′ is synthesised at the DNA template as the tight coupling suggests, this affinity might increase the possibility of A′ remaining there and not diffusing to another phage DNA molecule.

Because the smaller gene *A* protein, A, and the other identified phage proteins are synthesised in the presence of rifampicin the results suggest that the 5′ end of the gene *A* message is unique. A promoter is presumed to be located at the beginning of gene *A*[17,18] because the observed gene *F* to gene *H* polarity has not been found to extend to gene *A*. Although ΦX174 mRNA has been found to be structurally stable in a macromolecular sense[17], it has been shown[19] that the functional half life of gene *F* mRNA from the related phage S13 follows a two-component curve: about 70% of functional message decays with a half life ($t_{1/2}$) of approximately 1.4 min and 30% with a $t_{1/2}$ of approximately 14 min. Since a promoter site is presumed to be at the beginning of gene *F* (ref. 18), the $t_{1/2}$ of approximately 1.4 min was suggested to be caused by rapid degradation of the 5′ end of the gene *F* message[19]. This model of degradation from the promoter end of phage mRNA[19] is consistent with our results for A′ synthesis. Quantitation of A′ synthesis immediately after the addition of rifampicin is impossible at this point in time because it is a minor peak in the total gel profile. When rifampicin and ^{3}H-lysine are added together, 15 min after infection, no detectable A′ is synthesised. The possibility remains that a small base-pairing region at the 5′ end of gene *A* message rather than selective degradation at the end could explain this phenomenon. However, the decrease in A synthesis after the addition of rifampicin (see Fig. 3*b*) supports the degradation model (Fig. 5). It is still not known whether there exists a promoter internal to gene A that might also explain the synthesis of the smaller gene *A* protein. If this were the correct explanation there would still be different mRNA stabilities for the A′ and A mRNAs.

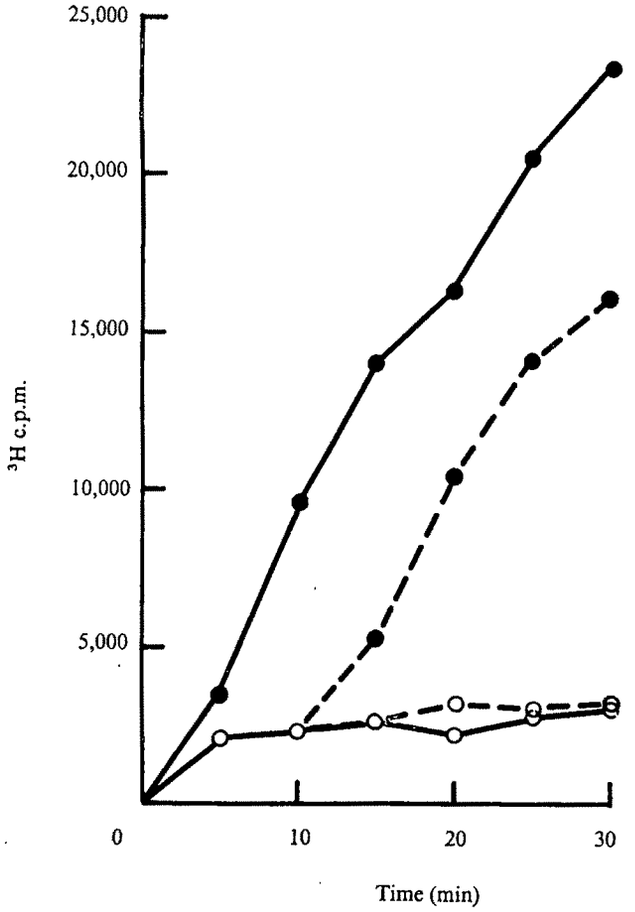

Fig. 4 ^{3}H-thymidine incorporation into mitomycin C-pretreated HF4704, ΦX174-infected cultures. Chloramphenicol (a gift from Parke-Davis Co.) was used at a concentration of 200 μg ml^{-1}. Cells were washed twice with HFC with ^{3}H-thymidine plus or minus rifampicin to remove the chloramphenicol. Rifampicin (Calbiochem) dissolved in dimethyl sulphoxide (20 mg ml^{-1}) was used at a concentration of 200 μg ml^{-1}. DNA was labelled by adding 20μCi ml^{-1} of ^{3}H-thymidine (New England Nuclear Corp., 6.7 Ci mmol^{-1} was added to the media containing 5 μg ml^{-1} thymine. No chloramphenicol (●—●); 200 μg ml^{-1} chloramphenicol from 0 to 30 min after infection (O—O); chloramphenicol present from 0 to 10 min after infection and then washed out (●···●); chloramphenicol washed out in the presence of 200 μg ml^{-1} of rifampicin 10 min after infection and the infection then allowed to proceed in the presence of rifampicin (O···O)

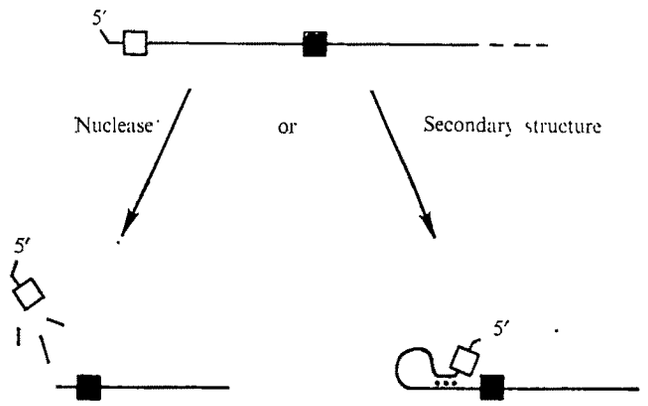

Fig. 5 Two models for gene *A* on RNA. □ A′ translational initiation site; A translational initiation site.

Table 1 Ratio of ^{3}H-lysine c.p.m. in A and A′ from *E. coli* HF4704 preirradiated with ultraviolet light to eliminate host protein synthesis[11,12] and then infected with the ΦX174 lysis mutant, N11

Conditions	A c.p.m./A′ c.p.m.
0-10 min pulse	1.9
10-30 min chase	1.9
10-20 min pulse	2.5
20-40 min chase	2.6
30-40 min pulse	2.8

The effect of rifampicin on ΦX174 DNA replication has been described before. Although it does not prevent complementary strand synthesis on the incoming single-stranded DNA molecule[20], as has been found for M13 (ref. 21), it has been shown to inhibit phage DNA replication when added before infection[22]. Addition of rifampicin later in infection allowed replication to occur. The assumption made in ref. 22 was that gene *A* mRNA was long lived and sufficient mRNA was available for gene *A* to function after the addition of rifampicin. The results are consistent with ours but our interpretation would be that once gene *A* is allowed to function, new A′ is not necessary for continued phage DNA replication.

Although the results suggest that the larger of the two gene *A* proteins is necessary for gene *A* function, they provide no explanation for the smaller protein, A. For reasons we cannot explain this molecule is not clearly separated from gene *H* protein when *bis* acrylamide is used as a cross-linker in SDS polyacrylamide gels. Since *bis* acrylamide has been commonly used by the other laboratories, our use of ethylene diacrylate as a cross-linker which clearly separates A and H (see Fig. 3*a* and *b*) explains why no other laboratory has associated a 35,000 molecular weight protein with gene *A*. No function has been established for A, though a minor virion component (approximately one molecule per particle[13]) described previously[13,23,24] has been

found to coelectrophorese with A isolated from single-stranded DNA cellulose columns.

This work was supported, in part, by grants from the US Public Health Service and the US National Science Foundation. M. H. is the recipient of a research career development award from the US Public Health Service.

Requirement for either DNA polymerase I or DNA polymerase III in post-replication repair in excision-proficient *Escherichia coli*

WHEN *Escherichia coli* bacteria deficient in excision repair (*uvr*) replicate their DNA after ultraviolet irradiation the newly-synthesised DNA contains gaps which are rejoined during subsequent incubation[1] by a postreplication repair process believed to be recombinational in nature[2]. Double mutants (*uvr recA*) deficient in both excision and post-replication repair are up to 25 times more sensitive to ultraviolet than those deficient in excision alone[3]. Bacteria deficient in excision repair and DNA polymerase I (*uvr polA*) in contrast are no more ultraviolet-sensitive than those deficient solely in excision[4], which might suggest that DNA polymerase I is not required for successful post-replication repair. The fact that DNA polymerase III seems to be able to substitute for DNA polymerase I in the repair of excision gaps[5], and type II DNA strand breaks[6] after X irradiation, however, indicates that DNA polymerase I cannot be excluded from involvement in post-replication repair if similar substitution by DNA polymerase III could occur there.

We have therefore examined the filling and joining of daughter-strand gaps in DNA synthesised after exposure to ultraviolet of bacteria deficient in DNA polymerase I (*polA*) and possessing temperature-sensitive DNA polymerase III activity (*dnaE*). The results are consistent with a requirement for either DNA polymerase I or DNA polymerase III in the gap-filling process.

We used *E.coli* BT1026 *dnaE polA*-1 *thy* (ref. 7) and 1026-1 which is a *polA*$^+$ MMS-resistant revertant isolated by W. Goebel. Some experiments were also carried out with a related strain BT1126 *dnaE polA*-1 *thy* (ref. 8) which carries a different *dnaE* mutation. All these strains are deficient in endonuclease I. The bacteria were grown at 33° C (permissive temperature) to about 2×10^8 ml^{-1} in M9 minimal medium supplemented with 1% casein hydrolysate and 2 μg ml^{-1} thymine and exposed to ultraviolet. They were then pulse labelled at 33° C by the addition of 100 μCi (^{3}H-methyl) thymidine ml^{-1} for a period of 7.5 to 12.5 min, filtered on membrane filters, washed with ten volumes of prewarmed buffer, and resuspended in unlabelled medium. The length of the pulse was adjusted to ensure that label uptake was not too dissimilar in irradiated and unirradiated cultures to minimise end-error artefact[9]. The molecular weight of the DNA synthesised during the pulse was examined by centrifugation through an alkaline sucrose density gradient immediately after the pulse and at various times during subsequent incubation of the bacteria at 33° C or 44° C (restrictive temperature for *dnaE*).

Strain 1026-1 is phenotypically PolA$^+$ DnaE$^+$ at 33° C and, as expected, filled gaps in daughter-strand DNA efficiently within 20 min at that temperature (Fig. 1*b*, *c*). At 44° C, daughter-strand gaps were also joined within 20 min. (Fig. 1*d*) indicating that postreplication repair can occur with no noticeable loss of efficiency in the absence of DNA polymerase III activity. It also shows that continued normal semiconservative replication is not necessary for post-replication gap filling.

As found with other *polA* bacteria[10], DNA synthesised in BT1026 at 33° C did not reach normal size as fast as in *polA*$^+$

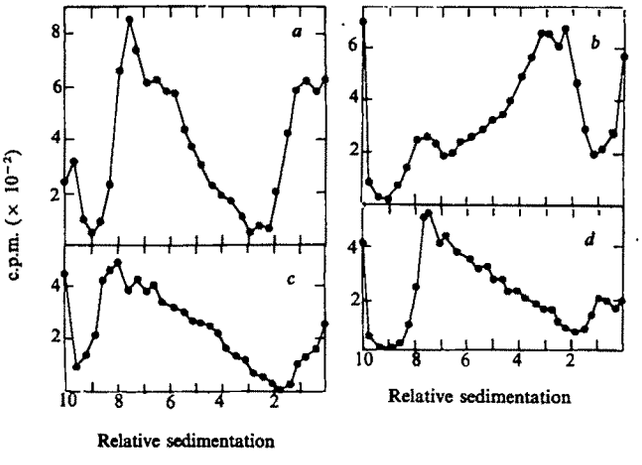

Fig. 1 Alkaline sucrose gradient sedimentation profiles of newly-synthesised DNA from *E. coli* 1026-1. *a* No ultraviolet, 7.5 min ^{3}H-thymidine pulse; *b* 100 ergs mm^{-2} ultraviolet, 10 min ^{3}H-thymidine pulse; *c*, 100 ergs mm^{-2} ultraviolet, 10 min ^{3}H-thymidine pulse, 20 min incubation at 33° C; *d*, 100 ergs mm^{-2} ultraviolet, 10 min ^{3}H-thymidine pulse, 20 min incubation at 44° C.

bacteria and about 20 min of subsequent incubation were needed before the normal profile was obtained (Fig. 2*a*). Further incubation did not result in any further increase in size. DNA synthesised in irradiated BT1026 was of smaller size. After 80 min incubation at 33° C, however, the DNA had been joined together to form pieces of normal size (Fig. 2*c*). Thus at 33° C, where BT1026 is phenotypically PolA$^-$ DnaE+, daughter-strand gaps could be filled indicating that a deficiency of DNA polymerase I does not prevent postreplication gap-filling although the process is slower in this strain.

In BT1126 there was postreplication repair during 30 min incubation at 33° C (Fig. 3*c*) indicating that in this strain the polymerase I deficiency did not markedly slow down the rate of gap filling. Other experiments have shown that *polA dnaE*$^+$ bacteria are able to carry out gap filling at 44° C (data not shown).

In contrast, in both BT1026 and BT1126 at 44° C, where the bacteria were phenotypically PolA DnaE$^-$, DNA that had been synthesised on an irradiated template (Fig. 3*b*) never increased to normal size and was degraded (Figs 2*d* and 3*d*). Degradation was faster in BT1126, the smaller pieces being completely acid-soluble within 15 min. Thus where both polymerase I and polymerase III were inactive there was no detectable filling of daughter-strand gaps. If there was any residual repair (perhaps involving DNA polymerase II) it was very limited in extent and did not give rise to DNA of normal size.

An interesting observation with BT1026 was that when unirradiated bacteria were transferred to 44° C after being pulse labelled at 33° C, the initially small DNA increased in

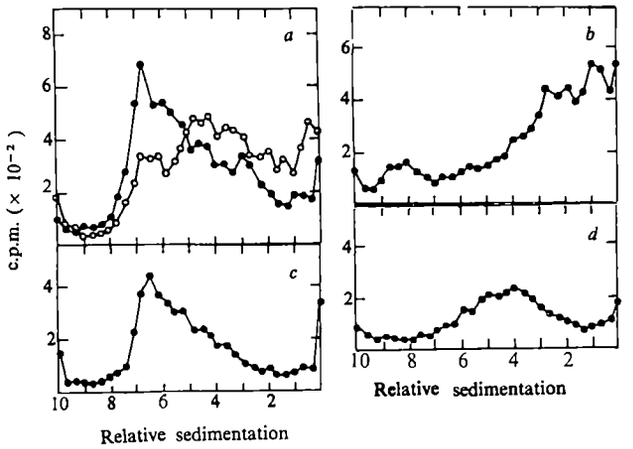

Fig. 2 Alkaline sucrose gradient sedimentation profiles of newly-synthesised DNA from *E. coli* 1026. *a*, No ultraviolet, 7.5 min ^{3}H-thymidine pulse with no (●) or 20 min (O) incubation at 33°; *b*, no ultraviolet, 7.5 min ^{3}H-thymidine pulse, with 20 min (●) or 80 min (O) incubation at 44° C; *c*, 100 ergs mm^{-2} ultraviolet, 12.5 min ^{3}H-thymidine pulse, no (●), 20 min (O) or 80 min (▲) incubation at 33°; *d*, 100 ergs mm^{-2} ultraviolet, 12.5 min ^{3}H-thymidine pulse, 20 min (●) or 80 min (O) incubation at 44° C.

size and sedimented at essentially the normal molecular weight after 20 min incubation but further incubation to 80 min resulted in a decrease in size without any loss of counts (Fig. 2*b*). We have no explanation for this observation.

We conclude that ultraviolet-irradiated bacteria deficient in either DNA polymerase I or DNA polymerase III are able to carry out postreplication gap filling. Bacteria deficient in both polymerases show little or no postreplication gap filling and tend to degrade newly-synthesised DNA. The results are consistent with the hypothesis that the two polymerases can substitute one for the other in daughter-strand gap filling, as in repair replication after excision repair[5]. The data do not give any indication as to which is the normal polymerase in conditions in which both enzymes are present and potentially active.

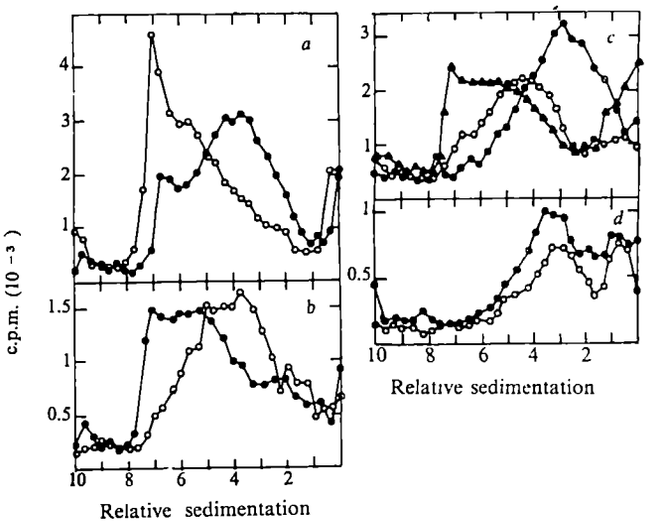

Fig. 3 Alkaline sucrose gradient sedimentation profiles of newly-synthesised DNA from *E. coli* BT1126. *a*, No ultraviolet, 7.5 min ^{3}H-thymidine pulse with no (●) or 30 min (O) incubation at 33 C; *b* 100 ergs mm^{-2} ultraviolet, 10 min ^{3}H-thymidine pulse; *c*, 100 ergs mm^{-2} ultraviolet, 10 min ^{3}H-thymidine pulse, 30 min incubation at 33° C; *d*, 100 ergs mm^{-2} ultraviolet 10 min ^{3}H thymidine pulse, 45 min incubation at 44° C.

It should be emphasised that these results have been obtained with excision-proficient strains. Their postreplication repair process may conceivably be different from that in excision-deficient strains. It is possible, for example, to formulate a model for excision-proficient bacteria in which photoproducts are excised from recently replicated parental DNA using the homologous parental strand transiently rehybridised with it as the template for repair replication. Such a process might be expected to require both excision and recombination genes. Circumstantial evidence for a process with such requirements has been recently reported[11].

Is the cytoplasm a site of nuclear DNA synthesis?

OBSERVATIONS which do not harmonise with the original self-replicative scheme of DNA synthesis have received little attention. In particular, interest in cytoplasmic DNA synthesis in eukaryotic cells has been limited to semiautonomous structures which contain DNA templates. But it was pointed out[1] as early as 1958 that transfer of genetic information between DNA, RNA and protein often can proceed in either direction. It is possible that an initial step of DNA synthesis, corresponding for example to RNA-primed synthesis of Okazaki fragments[2,3], may generally occur out of cell nuclei and without direct participation of a DNA template.

Table 1 Incorporation of ^{14}C-thymidine into nuclear, organellar and cytoplasmic DNA fractions of germinating wheat embryos

Germination time (h)	DNA amount and radioactivity (per 100 embryos)					
	Nuclear		Organellar		Cytoplasmic	
	(μg)	(d.p.m.)	(μg)	(d.p.m.)	(μg)	(d.p.m.)
3	125	<10	15	<10	<5	<10
6	120	250	20	<10	<5	220
12	140	640	25	40	<5	210
24	170	1,350	20	150	<5	120

A sample of 350 wheat grains was surface sterilised with 2% NaClO and left at 2° C for 8 h with 10 ml of ^{14}C-thymidine solution (1.0 μCi ml^{-1}, 53 μC-μmol^{-1}). The prelabelled sample was washed with water and allowed to germinate at 22° C for the indicated time. Embryos were then separated and ground in a mortar with 10 ml of ice-cold 0.25 M sucrose containing 15 mM potassium phosphate (*p*H 7.3) and 10 mM $MgCl_2$. The homogenate was filtered through a nylon tissue and fractionated by centrifugation. Nuclear (1,000*g* pellet), organellar (18,000*g* pellet) and cytoplasmic (18,000*g* supernatant) fractions were obtained and washed with 0.3 M $HClO_4$ containing 1 mM thymidine. RNA was removed by an alkaline hydrolysis (0.3 M KOH, 37° C, 15 h) and DNA fraction obtained as an acid hydrolysate (0.5 M HCl, 100° C, 30 min). The acid hydrolysate was applied to paper chromatography in a water-saturated butan-1-ol solvent system[10]. Adenine and guanine were eluted from the corresponding spots and determined spectrophotometrically to calculate the DNA content. The origin, containing a mixture of pyrimidine nucleotides resulting from the acid hydrolysis of DNA, was used for the measurement of radioactivity in a Packard liquid scintillation counter.

We tested for a prenuclear stage of DNA formation in germinating wheat embryo, in which biosynthetic events triggered after the breaking of dormancy are naturally synchronised[4]. It has been observed[5] that incorporation of thymidine into DNA of germinating wheat seeds begins only after some preliminary activation of RNA synthesis is completed, implying an RNA-dependent DNA synthesis in this system. To check whether the cytoplasm may contribute to the early stage of DNA synthesis, wheat grains were prelabelled with ^{14}C-thymidine and germinated for various periods. Total amounts and radioactivities of nuclear, organellar and cytoplasmic DNA of the embryo were then determined (Table 1).

I found that after 6 h germination radioactive DNA appeared in the nuclear and soluble cytoplasmic fractions (Table 1). Specific radioactivity of the cytoplasmic DNA was, however, at least 20-fold higher than that of the nuclear DNA. As germination proceeded further the radioactivity of the cytoplasmic DNA decreased considerably and that of the nuclear DNA rose correspondingly. These observations are consistent with the hypothesis of a precursor–product relationship between the cytoplasmic and nuclear DNA. Rapid activation of cytoplasmic DNA synthesis in an early response to proliferative stimuli has been observed in other eukaryotic cells[6-8]. The experimental data do not exclude the possibility of an independent synthesis of the cytoplasmic and nuclear DNA. But the only explicable reason for the synthesis of deoxyribopolynucleotides in the supernatant fraction of the cytoplasm, which is virtually free of mature DNA molecules, is to supply them to the nucleus and other DNA-containing structures.

Another explanation is the transport of informational DNA from nucleus to cytoplasm, which has been reported for cultured animal cells[9]. This explanation, however, can be hardly extended to the germinating wheat embryo, where radioactivity of the cytoplasmic DNA decreases after the nuclear DNA becomes highly radioactive. The same observation seems to exclude the possibility of a significant contamination of the cytoplasmic fraction by nuclear DNA during the homogenate fractionation. I have therefore come to the conclusion that the cytoplasmic DNA synthesis may represent a prenuclear stage of the genome replication.

I thank E. Kraszewska for technical assistance. This work was supported by the Polish Academy of Sciences and, in part, by the US Department of Agriculture, Agricultural Research Service.

Effect of 5-bromodeoxyuridine on the size distribution of DNAs isolated from sea urchin embryos

5-BROMODEOXYURIDINE (BUdR), an analogue of thymidine, has been shown to selectively inhibit cell differentiation in various cell types and development of embryos, without affecting cell maintenance capabilities[1]. Gontcharoff and Mazia[2] demonstrated that exposure of newly fertilised sea urchin eggs or early cleavage stage embryos to BUdR resulted in embryos which did not gastrulate or produce echinochrome pigment. From this laboratory evidence has been reported[3] for a BUdR-induced modification of DNA replication in developing sea urchin embyros. Pulse-chase experiments in sea urchin gastrulae demonstrated that newly synthesised low molecular weight (8-15S) nuclear DNA labelled with ^{3}H-BUdR was not readily chased by unlabelled BUdR into higher molecular weight DNA. In contrast, 8-15S DNA labelled with ^{3}H-thymidine was converted into higher molecular weight DNA during a relatively short chase period with unlabelled thymidine. This data suggested the incorporation of BUdR into newly synthesised low

molecular weight DNA molecules in embryos might prevent or slow the rate of normal linkage of such molecules into higher molecular weight DNA.

We report here that morula and blastula stage sea urchin embryos grown continuously from fertilisation in the presence of BUdR accumulate DNA molecules (30-60S) which are not integrated into higher molecular weight bulk DNA.

The effect of BUdR on the size distribution of isolated long term ^{32}P-labelled DNA from embyos was determined on neutral sucrose gradients. A control culture of morula stage embryos grown continuously from fertilisation in the presence of ^{3}H-thymidine was collected and mixed with a culture of morula stage embryos similarly labelled with ^{32}P but grown continuously in the presence of either 50 μg ml^{-1} BUdR or 50 μg ml^{-1} thymidine (TdR). DNA was coisolated from mixtures of ^{3}H- and ^{32}P-labelled embryos and centrifuged through a neutral sucrose gradient as described in the legend to Fig. 1. ^{32}P-labelled morula stage DNA isolated from embryos grown in the presence of 50 μg ml^{-1} TdR sedimented with a distribution similar to ^{3}H-labelled morula stage DNA coisolated from embryos grown without added nucleoside (Fig. 1*a*). In contrast, a portion of ^{32}P-labelled morula stage DNA isolated from embryos grown in the presence of 50 μg ml^{-1} BUdR sedimented more slowly than ^{3}H-labelled morula DNA coisolated from the control culture (Fig. 1*b*). Similar differences in sedimentation distribution of control DNAs and DNAs isolated from embryos grown in the presence of BUdR were obtained from blastula stage embryos.

A summary of data demonstrating the effect of BUdR on the size distribution of ^{32}P-labelled morula and blastula stage DNAs on neutral sucrose gradients is presented in Table 1. In addition to the coisolation and sedimentation of BUdR and control DNAs as shown in Fig. 1, long term ^{32}P-labelled DNAs were isolated separately and consedimented with marker ^{3}H-DNA from bacteriophage Φ80. This facilitated a determination of the proportion of different size ranges of sea urchin DNA compared with the position of the marker DNA. A portion of the ^{32}P-labelled DNAs isolated from both morula and blastula stage embryos grown in the presence of BUdR sediments more slowly than ^{32}P-labelled DNA isolated from control cultures. The difference is represented by a decrease in the proportion of DNA sedimenting at greater than 60S and a corresponding increase of 8–10% in the morula and 3–5% in the blastula stage DNA sedimenting in a range from 30–60S. That this difference in sedimentation distribution is specifically the result of the presence of BUdR during embryogenesis rather than excess deoxyribonucleosides in the culture medium is demonstrated by the close similarity between the sedimentation distribution of DNA isolated from control cultures and those in which the embryos were grown in 50 μg ml^{-1} TdR (Fig. 1*a* and Table 1).

To ensure that the difference in sedimentation of ^{32}P-labelled DNAs obtained from embryos grown in the presence of BUdR (compared with control DNAs) was not the result of ^{32}P-containing molecules other than DNA, samples of the sea urchin DNA preparations labelled with ^{32}P were subjected to enzymatic and alkaline treatment. More than 90% of the ^{32}P was resistant to a mixture of pancreeatic and T_1 RNases; more than 95% of the radioactivity was DNase-sensitive; more than 85% of the ^{32}P was resistant to 0.2 M NaOH at 60° C for 1 h. Thus at least 85% of the ^{32}P recovered was in DNA. More importantly, ^{32}P-labelled morula stage DNA isolated from embryos grown in the presence of BUdR was incubated with or without the addition of DNase and then centrifuged through neutral sucrose gradients (data not shown). The small percentage of DNase-resistant ^{32}P was found near the top of the gradient. Therefore, we believe that the shift in distribution of ^{32}P observed in the sedimentation profiles of DNAs isolated from embryos grown in the presence of BUdR (Fig. 1*b* and Table 1) represents ^{32}P-containing DNA.

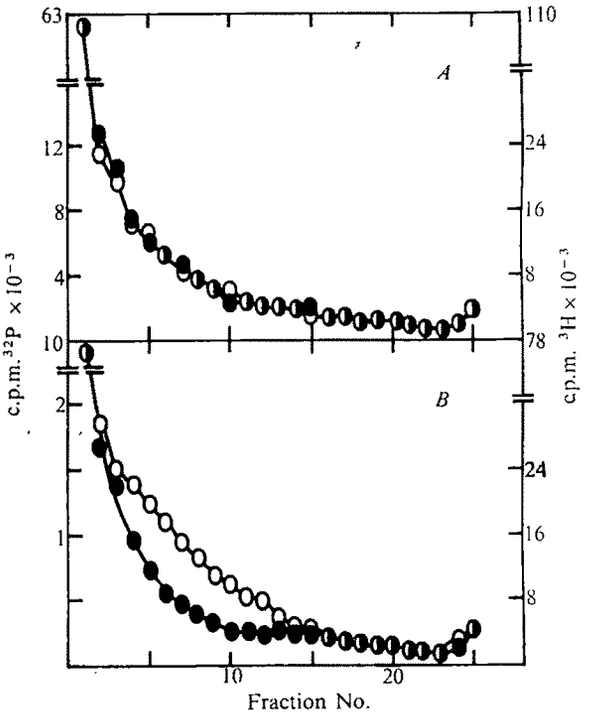

Fig. 1 Comparison on neutral sucrose gradients of profiles of control DNAs and DNAs synthesised in the presence of BUdR. *Strongylocentrotus purpuratus* embryos were cultured[3] in artificial seawater[11] containing penicillin and streptomycin to the morula stage of development: *A*, DNA coisolated from embryos grown under normal conditions in the presence of 2 μCi ml^{-1} ^{3}H-methyl-thymidine (20 Ci mmol^{-1}) and then mixed after growth with embryos grown in the presence of 50 μg ml^{-1} TdR with 1 μCi ml^{-1} ^{32}P; *B*, DNA coisolated from control embryos grown under normal conditions in the presence of ^{3}H-TdR and then mixed with embryos grown in the presence of 50 μg ml^{-1} BUdR and 1 μCi ml^{-1} ^{32}P. In all comparative experiments cultures were derived from a single batch of eggs pooled from several females. Nucleosides were added immediately after fertilisation and radioisotopes were added 10 min after fertilisation, all being present until the embryos were collected. Each 100 ml culture of embryos was killed by the addition of an equal volume of 20% phenol (freshly redistilled, saturated with 50 mM sodium phosphate buffer, *p*H 7.0) in –20° C ethanol. The embryos were pelleted from the alcohol-phenol solution by centrifugation at 10,000 *g* for 15 min and resuspended in 100 ml of 100% ethanol. After an additional centrifugation, embryos were resuspended and combined in a total of 10 ml of buffer which was 50 mM Tris, 50 mM EDTA, *p*H 8.5 at 37° C. Cells were lysed by the addition of sodium dodecylsulphate to 0.5%. Pronase (predigested 1.5 h at 37° C in Tris-EDTA buffer) was added to 1 mg ml^{-1} and the lysate was kept overnight at 37° C. α-Amylase (Worthington, twice crystallised) was added to 100 μg ml^{-1} and pancreatic RNase (Worthington, stock solution is 2 mg ml^{-1} in 0.15 M NaCl, heated to 85° C for 20 min) to 20 μg ml^{-1}; the mixture was then incubated at 37° C for 2 h. Predigested pronase was then added to 100 μg ml^{-1} and the DNA was held at 37° C overnight. The resulting DNA solution was extracted three times with phenol and extensively dialysed against 1 × SSC (SSC is 0.15 M NaCl, 0.015 M sodium citrate). Approximately 45 μg of the ^{3}H- and ^{32}P-labelled coisolated DNA was brought to a final volume of 1.0 ml in 1 × SSC and layered onto a 30 ml 5-20% sucrose gradient containing 1 M NaCl, 20 mM Tris-HCl, 1 mM EDTA, *p*H 7.3. Centrifugation was in a Beckman SW 25.1 rotor for 10 h at 24,000 r.p.m. at 20° C. Fractions were collected from the bottom of the gradient and precipitated at 4° C by the addition of 2 volumes of 10% trichloroacetic acid and 25 μg bovine serum albumen. Fractions were collected on Whatman GF/A filters, dried, and counted in toluene-based scintillation fluid. O, ^{32}P; ●, ^{3}H.

It should be noted that the portion of isolated bulk DNA which contains radioactivity represents only nuclear DNA, for mitochondrial DNA replication does not occur in sea urchin embryos until after gastrulation[4,5].

Table 1 Summary of data demonstrating an effect by BUdR on sedimentation in neutral sucrose gradients of ^{32}P-labelled DNAs isolated from sea urchins embryos.

$S_{20,w}$ distribution*	Calculated† molecular weight $\times 10^{-6}$	% of total counts Morula Control	Morula BUdR	Morula TdR	Blastula Control	Blastula BUdR	Blastula TdR
>60	>154	47.9	38.7	50.4	70.3	64.9	70.9

DNA was isolated and centrifuged as described in Fig. 1, except that ^{32}P-labelled DNA was not coisolated with ^{3}H-labelled DNA. The DNAs were extracted from embryos grown without added nucleoside or with the addition of BUdR or TdR to 50 μg ml^{-1}.
* $S_{20,w}$ values were determined by the relative sedimentation distance of freshly prepared ^{3}H-TdR-labelled φ80 DNA[12] cosedimented in each gradient.
† Molecular weight was calculated from $S_{20,w}$ values using the equations of Studier[13]. Native φ80 phage DNA has a calculated $S_{20,w}$ value of 33.4 based on a molecular weight of 28.6×10^6 (ref. 14).

Thus it seems that the ^{32}P-labelled nuclear DNA isolated from early stage sea urchin embryos allowed to develop in the presence of BUdR contains an increased proportion of molecules in the 30–60S range, compared with DNA isolated from embryos grown in the absence of BUdR or in the presence of TdR. This shift in the size distribution of DNA could result from at least one of several mechanisms: (1) certain sequences in higher molecular weight DNA synthesised in the presence of BUdR may be sensitive to excision *in vivo* or breakage during the isolation of the DNA; (2) BUdR may induce the amplification of some episomal DNA; (3) certain newly synthesised DNA molecules may not be able to integrate into bulk DNA when substituted with BUdR. Though the data presented do not distinguish between the above possibilities, certain indirect evidence may favour the latter mechanism.

(1) Birnboim *et al.*[6] have reported the presence of long (greater than 4S) pyrimidine stretches which remain after hydrolysis of HeLa cell DNA in the presence of formic acid and diphenylamine. If the incorporation of BUdR renders DNA more sensitive to excision *in vivo* or breakage during isolation, one might expect incorporation of BUdR to change the size distribution of such long pyrimidine lengths. A comparison of ^{32}P-labelled pyrimidine runs obtained from DNAs isolated from embryos grown in the presence or absence of BUdR demonstrated no difference in length distributions (S.T.C., unpublished observation). This might be taken as evidence against excision or breakage of BUdR-substituted DNA within long pyrimidine runs, though such an occurrence in a small proportion of the pyrimidine lengths or in short oligopyrimidines would not be detected.

(2) Kotzin and Baker[3] reported that 8–15S (alkaline sucrose gradient) newly synthesised sea urchin DNA (apparently occurring as a normal intermediate in DNA synthesis[7]), pulse-labelled with ^{3}H-BUdR, could not be chased into higher molecular weight DNA with unlabelled BUdR during a 20 min chase period. These experiments suggest that a portion of newly synthesised short DNA pieces either cannot integrate with existing higher molecular weight DNA, or the rate of integration is retarded by the BUdR. In the results shown in Fig. 1 and Table 1, exposure of embryos to BUdR over a long period results in accumulation of pieces longer than the 8–15S size range seen at the end of the relatively short pulse-chase period previously described[3]. Thus, it seems possible that BUdR retards rather than prevents the integration of short pieces of certain nuclear DNAs. The 30–60S pices accumulated in embryos continuously grown in BUdR may, however, represent a maximum size beyond which certain DNA sequences cannot increase by acquiring smaller DNA pieces or by integrating into existing longer pieces.

There is some support for the possibility that particular nuclear DNA sequences might incorporate BUdR preferentially. Walther *et al.*[8] report that in the developing pancreas there is a low molecular weight, double-stranded, nuclear DNA fraction (detected with ^{3}H-thymidine) which normally does not incorporate into higher molecular weight DNA. This DNA fraction preferentially incorporates BUdR relative to bulk DNA[1]. Reassociation studies demonstrate that this 15–25S fraction of DNA is not a random sample of chromosomal sequences and does not contain highly repetitive sequences[1].

It is perhaps interesting to note that the size of the DNA molecules which seem to be affected by exposure to BUdR during replication (30–60S in the work reported here) are within the size range reported for the replicons of several higher cell types[9,10]. This suggests a possible mechanism for the selective effect of BUdR on certain specialised functions associated with differentiation. Substitution of BUdR for thymidine could preferentially prevent or retard integration, into higher molecular weight DNA, of those replicons containing sequences coding for or regulating products related to specialised functions associated with differentiation. If such integration is necessary for regulation of gene expression it would be possible for this thymidine analogue to inhibit differentiation without affecting cell viability and proliferation.

Are 'N bands' selective staining of specific heterochromatin?

BY *in situ* DNA–RNA-hybridisation and the association patterns in meiotic and mitotic chromosomes, the nucleolus organiser regions (NOR) have been localised on specific chromosomal segments of some mammalian species[1–4]. Matsui and Sasaki[5] described a staining technique ('N bands') which was assumed to stain the NOR of mammalian chromosomes with high specificity.

This assumption was based on the following findings. First, the satellites of human acrocentric chromosomes are exclusively stained but not the centromeres, short arms or stalks of satellites. From their interpretation of the literature[1,2], they believe that the NOR is located in the satellites of human D and G group chromosomes. Second, N bands appear in the secondary constriction of the rat kangaroo (*Potorous tridactylis*) X chromosome to which the NOR is assigned[6,7]. Third, N bands are visible in the presumed nucleolus organiser regions of several other species (*Rattus norvegicus, Crisetulus griseus, Muntiacus muntiac, Macaca fasicularis* and *Mus musculus*).

We have checked these hypotheses using essentially the same technique[5] with chromosome preparations of human lymphocytes, fibroblasts of the vole species *Microtus oeconomus* and *Microtus ochrogaster*, and the dormouse *Eliomys quercinus*.

In accordance with the results of Matsui and Sasaki, on human metaphase plates we found distinctive red spots on the satellites of acrocentric chromosomes (Fig. 1). Yet, not all satellites stain with this technique as should be the case if this technique gives a differential staining of the NOR. In contrast to the statements of these authors we observed an additional differential staining of the short arm of one D group chromosomes (Fig. 1). No staining of the stalks of satellites could be achieved in all metaphases analysed.

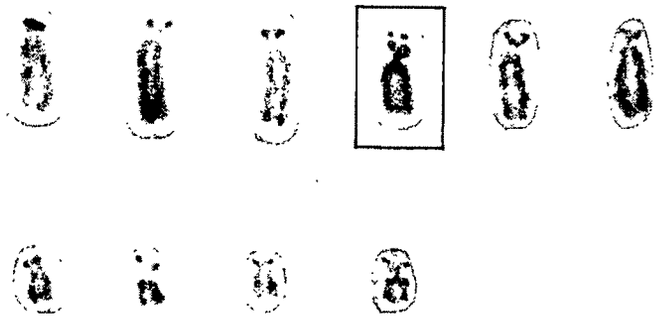

Fig. 1 D and G group chromosomes of a human lymphocyte in metaphase with N bands. Note the polymorphism of the N bands on the short arm and satellites in the marked D chromosome.

As the nucleolus organiser regions in human chromosomes have been assigned to the secondary constrictions of the acrocentric chromosomes[1,2,4], it has to be concluded that the N-band technique does not give a differential staining of the human NOR.

In metaphase chromosomes of *M. oeconomus*[13] N bands were visible at the short arms of the acrocentric chromosomes 13 and 14. The unpublished results of W. Engel, H. Hoehn and W. Krone have shown that the short arm and the secondary constriction of the long arm of chromosome 14 are involved in 'satellite associations'.

Accordingly, in the long arm of chromosome 14 the NOR shows no N band and the N band of chromosome 13 is not correspondent to a NOR. These findings are evidence that the N-band positive sites do not coincide with NORs also in this species. We also treated metaphase plates of *M. ochrogaster* and *Eliomys quercinus* with the N band technique. It was not possible to detect any N bands in either species. As these species are expected to possess NOR, it is obvious that N bands do not represent a differential staining of the NOR.

In many of the species investigated, heterochromatic regions are located adjacent to the NORs. This is true for man[9], mouse[12,11], Indian muntjac[3,8], and the short arm of chromosome 14 in *M. oeconomus*, for example. In a species without heterochromatin (*Eliomys quercinus*, our unpublished results) no N bands can be found. Therefore we conclude that N bands correspond to a specific kind of heterochromatin which is situated adjacent to the NOR in most instances.

We have circumstantial evidence[10] that the production of G bands is determined by qualitative differences of nonhistone proteins along the chromosomes. Matsui and Sasaki[5] give evidence that the specific nonhistone proteins are stained with the N-band technique. Therefore one may assume that N bands reflect nonhistone proteins corresponding to a special kind of heterochromatin. Though N bands apparently do not stain the NORs, they are useful markers in human cytogenetics like other special staining methods.

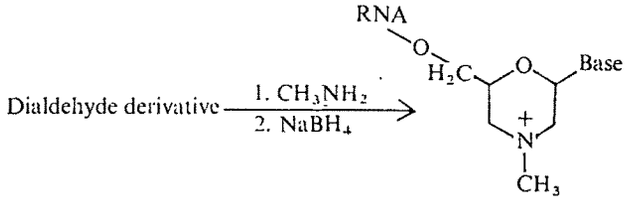
Messenger and aminoacylation functions of brome mosaic virus RNA after chemical modification of 3′ terminus

THE ability of RNA from several plant viruses to bind a specific amino acid in a manner like tRNA is now well established. All members of the tymovirus group so far examined contain RNA which can bind valine [1-3]; all members of the bromovirus group bind tyrosine (ref. 4 and T.C.H., in preparation), and tobacco mosaic virus (TMV) RNA binds histidine[5]. The ubiquity of the reaction, and the similarity of the esterification to that of aminoacylation of tRNA indicates that a significant biological function for the property exists. A tRNA-like function such as that of a virus-specific tRNA, or a mis-sense tRNA seems plausible. Although there is evidence that turnip yellow mosaic virus (TYMV) RNA, or a fragment containing the 3′ terminus of TYMV RNA, may donate valine to nascent polypeptides[6], it has been established that tyrosine, bound to brome mosaic virus (BMV) RNA, is not donated to peptidyl material in a cell-free system from wheat embryo when directed by viral, plant, or synthetic messenger RNA (ref. 7).

Of the several viral RNAs capable of aminoacylation, only BMV RNA has been shown to function as an efficient messenger,



capable of directing the synthesis of authentic viral proteins in a cell-free system[8]. Therefore, with BMV RNA, a unique opportunity exists for determining the inter-relationship between aminoacylation activity and messenger function of viral RNA. A useful approach to understanding this inter-relationship is to test retention of these activities following chemical modification of the viral RNA. A definitive modification should be that of oxidation of the 3′ terminus as this is known to prevent aminoacylation of tRNA (ref. 9).

Two procedures were adopted for RNA modification[10]. First, the 3′ end of BMV RNA was oxidised to the dialdehyde derivative with periodate according to the reaction:

Dialdehyde derivative

It is known, however, that the oxidised 3′ end of the RNA can be removed by an amine-catalysed β-elimination reaction[11], and therefore, the possibility existed that under our *in vitro* reaction conditions replacement of the terminal pA_{OH} could occur, thereby restoring the RNA to its original form. To prevent such repair of the 3′ terminus the second modification procedure used was the preparation of the morpholine derivative according to the reaction:

Morpholine derivative

Both modification procedures resulted in the loss of the ability of the BMV RNA to accept an amino acid but no quantitative difference in messenger function was observed (Table 1).

To determine whether qualitative differences exist in the pattern of proteins synthesised under the direction of the modified RNA, the products synthesised *in vitro* were subjected to sodium dodecyl sulphate (SDS)-polyacrylamide gel electrophoresis. Protein synthesised using unmodified BMV RNA (comprised of components 1,2,3, and 4) (ref. 12) as messenger consists mostly of BMV coat protein, together with a small amount of a protein designated protein 3a and some uncompleted proteins (Fig. 1*a*). The electrophoretic profiles of proteins synthesised under the direction of the dialdehyde derivative, and of the morpholine derivative, appear in Fig. 1*b* and *c*, respectively. The pattern of radioactivity obtained for products of the reaction directed by the dialdehyde derivative (Fig. 1*b*) was identical to that of the unmodified BMV RNA products (Fig. 1*a*), confirming that normal products can be synthesised by viral RNA lacking an aminoacylatable 3′ terminus. Analysis of the products of the reaction directed by the morpholine derivative (Fig. 1*c*) also showed the presence of coat protein and protein 3a. In this case, however, a relatively higher proportion of protein 3a, and a correspondingly lower proportion of coat protein was synthesised. The reason for this difference is unknown. A likely possibility is that configurational changes

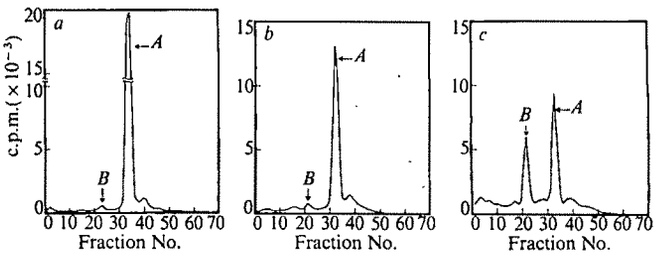


Fig. 1 Polyacrylamide gel patterns of products synthesised *in vitro* under the direction of modified and unmodified BMV RNA. Conditions for *in vitro* protein synthesis and gel electrophoresis were as previously described[8]. ^{14}C-leucine was used as label. The products synthesised under the direction of unmodified RNA (control), the dialdehyde derivative of the RNA, and the morpholine derivative of the RNA are shown in (*a*), (*b*), and (*c*), respectively. Electrophoresis was from left to right. *A*, Coat protein; *B*, protein 3a.

occurred in the BMV RNA molecules after methylamine and sodium borohydride treatment, causing alterations in the affinities of ribosomes for the different cistrons. While this in itself is an interesting finding, the fact that both products synthesised under the direction of the modified RNAs are similar to proteins obtained using native BMV RNA as messenger strongly suggests that aminoacylation of BMV RNA is not an obligatory step for translation of this viral RNA.

Although the apparent tRNA-like structure of BMV RNA, TYMV RNA, TMV RNA, and other plant virus RNAs makes a tRNA-like function an attractive possibility, the present data greatly detract from the proposition that the biological role of aminoacylation of plant virus RNA is directly related to the donation of an amino acid to a viral peptide. The present results do not eliminate the possibility of such a role as a helpful, but not obligatory, step in viral growth. Nevertheless, it now seems more likely that binding of an amino acid to the virus RNA could be involved as a recognition signal for the replicase as proposed by Litvak and coworkers[13], or could function as a regulatory system such as that proposed by Kolakofsky and Weissmann for phage Qβ (ref. 14).

Table 1 Effect of modification of 3′ terminus of BMV RNA on its tyrosine binding ability and on its activity in stimulating amino acid incorporation.

RNA added	Tyrosine binding (c.p.m.)	Amino acid incorporation (c.p.m.)
Control	10,239	13,641
Periodate derivative	254	13,000
Morpholine derivative	495	13,882

BMV RNA was modified according to the procedures described by Fahnestock and Nomura[10] for modification of *Escherichia coli* 5S rRNA. For preparing the control RNA, all the manipulations for periodate oxidation and methylamine-borohydride derivatisation were carried out except that the modifying agents were omitted. Conditions for BMV RNA aminoacylation were as previously described[4], each reaction (0.1 ml) containing 15 μg of RNA. A 20 μl sample was assayed for ^{3}H-tyrosine binding to virus RNA after 30 min incubation at 30°C. Amino acid incorporation conditions were as previously described[8]. Each incorporation mixture (175 μl) contained 30 μg of RNA and 0.5 μCi of a mixture of ^{14}C-labelled alanine, arginine, leucine, and lysine. Aliquots of 50 μl were counted to determine amino acid incorporation into protein.

Virus-induced cell fusion enhanced by phytohaemagglutinin

ONCOGENIC transformation by viruses or chemicals[1–5], treatment with proteolytic enzymes[1,6] and infection with nononcogenic enveloped viruses[7,8], produce cell surface alterations that increase cellular susceptibility to agglutination by plant lectins. More recently, lectins have been used to modify the replication and cytopathogenicity of enveloped viruses grown in normal cells[9,10]. It has been shown that treatment of cells with con A inhibits paramyxovirus-induced cell fusion.[11] In contrast, the results reported here indicate that another plant lectin, phytohaemagglutinin (PHA), can enhance the fusion of cells infected with the paramyxovirus Newcastle disease virus (NDV).

Freeze-dried PHA (Wellcome Reagents Ltd., Beckenham, Kent) was reconstituted in phosphate-buffered saline (PBS) and cells were treated with 1.0 ml diluted in maintenance medium at the concentrations described below. The properties of the NDV strains, cell culture methods, infection of cell cultures and measurement of the extent of cell fusion have been described[12–14]. All cell cultures were grown on coverslips in Leighton tubes at 37° C.

To demonstrate the effect of different concentrations of PHA on NDV-induced cell fusion from within[15], virus was removed 1 h after infection and replaced with 1.0 ml of medium containing different dilutions of PHA, incubated for a further 8 h at 37° C in the presence of PHA, finally fixed and stained and the extent of cell fusion measured. Fusion of BHK 21 cells infected with NDV strain Herts was enhanced in the presence of PHA (Fig. 1). Incubation of PHA with 0.5 M N-acetyl-galactosamine, a haptenic inhibitor of PHA, for 1 h at 37° C before addition to infected cell cultures eliminated its ability to enhance fusion

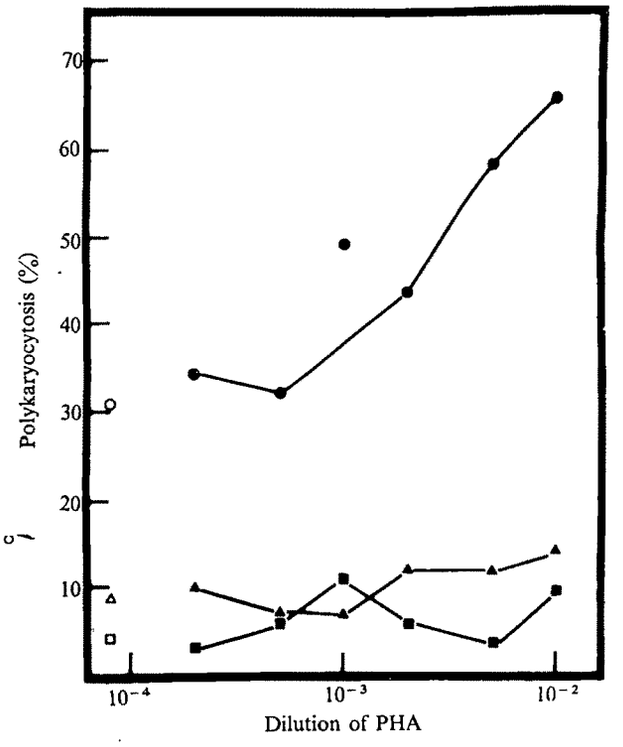

Fig. 1 Effect of different concentrations of PHA on fusion of BHK-21 cells infected with 25 EID_{50}/cell NDV-Herts (●), 50 EID_{50}/cell NDV-Queensland (■), and uninfected control cells (▲). At 1 h after infection, virus was replaced with PHA diluted in maintenance medium. Polykaryocytosis was estimated 8 h after infection. O, □, △, Fusion in the absence of PHA.

from within by strain Herts. PHA had no effect, however, on the fusion of cells infected with NDV strain Queensland (a non-fusing strain) or uninfected control cells. The time of addition of PHA after infection was important in determining the degree of enhancement of cell fusion (Fig. 2). The length of time for which PHA is in contact with the cells is not important, however, as similar enhancement of fusion from within was found after exposure to PHA for 90 min or 8 h with PHA added 1 h after infection. It is more likely that the decrease in enhancement is related to the progression of virus replication and fusion (Fig. 2), that is, once a fusion event has taken place there can be no enhancement of that event.

Fusion from without (ref. 15) was also enhanced by pretreatment with PHA. Maximum enhancement was recorded if cell cultures were treated with PHA (10^{-2} dilution) for 1.5 h or more before infection. Such treatment before infection with 1600 EID_{50}/cell NDV-Herts induced 57.5% polykaryocytosis compared to 37.2% in untreated and 4.1% in uninfected cell cultures. Experiments using PHA-Sepharose 4B conjugate gave similar results and showed that it was not necessary for PHA to enter the cell to cause enhancement. Cells were pretreated for 1.5 h with PHA-Sepharose, which had been washed extensively to remove any free PHA and diluted to give similar activity (as titrated by haemagglutination) to the unbound PHA used, and then infected with 1600 EID_{50}/cell NDV-Herts. Three hours after infection, cells treated with PHA-Sepharose showed 57.5% polykaryocytosis compared to 37.2% in infected, untreated cells and 3.9% in uninfected cells.

The results presented here indicate that PHA has a marked enhancing effect on cell fusion by NDV and that PHA acts rapidly on a prefusion event and does not require the presence of virus products at the cell surface for the initial interaction. The results obtained with PHA-Sepharose indicate that, as with lymphocyte

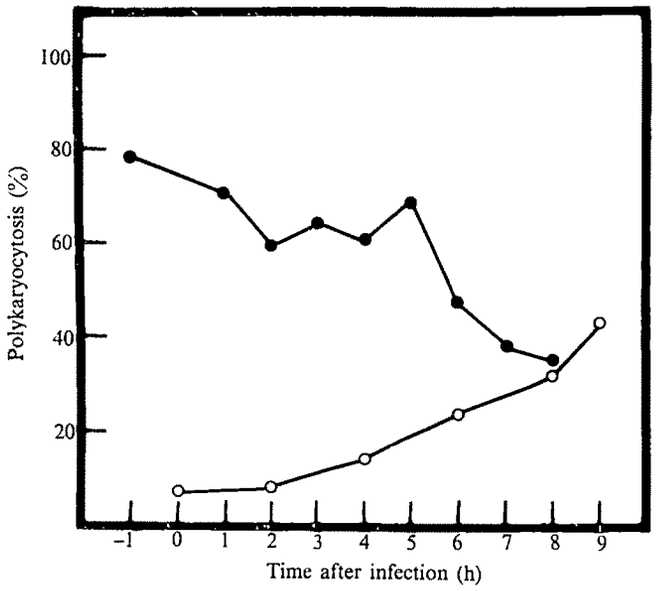

Fig. 2 Effect of PHA (10^{-2} dilution) added at different times on cell fusion of BHK-21 cells at 9 h after infection with 25 EID_{50}/cell NDV-Herts (●). Fusion in untreated cells at different times after infection with NDV-Herts is also shown (○).

activation[16], PHA does not have to enter the cell to be effective.

Further work is required to determine the mode of action of PHA. It may be significant, however, that other studies have indicated that lysosome fragility follows stimulation of lymphocytes with PHA[17] and we have previously suggested the possible role of lysosomal enzymes in virus-induced cell fusion[18].

This work was aided by a grant from the National Cancer Institute of the United States, and a grant from the Agriculture Research Council. G.H. and H.W. were supported by the Agriculture Research Council. PHA-Sepharose was a gift from Dr K. H. Fantes, Wellcome Research Laboratories, Beckenham.

Thymus involvement in female sexual maturation

It is now established that the thymus plays a critical role in a variety of immunological functions. Evidence that the thymus can also function as an endocrine gland has mainly been derived from immunological investigations[1,2]. Because endocrine glands do not function independently, it is likely that the thymus is involved in a number of endocrine functions and some experimental data support such an assumption. Thus, hypothyroidism and persistence of the foetal zone in the adrenals is observed in congenitally athymic nude mice[3] and degranulation of pituitary eosinophil cells occurred following neonatal thymectomy in mice[4].

Here we present experimental evidence that the thymus also influences the maturation of female sexual function during a critical period of development.

Conventional female Charles River mice were surgically thymectomised or sham-operated when 2 or 10 d old. Mice thymectomised on day 2 were implanted on day 3 with 1–2 thymus glands obtained from male or female animals of the same age and other groups of 3 d old were injected intraperitoneally with 5×10^6 thymocytes from adult mice (2–3 months old). Among the parameters studied in the different experimental groups were vaginal opening time (VOT) (the day of complete vaginal opening with full differentiation of the external sexual structures); the sexual cycle (based on daily cytological studies of the vaginal contents), and the morphology of the ovary and uterus (based on gross inspection and conventional histology). The criterion for defining puberty was the vaginal opening time followed by the first oestrus appearing within 4 d.

On completion of the various experiments, all mice were killed for gross morphological and histological inspection of the sexual organs. Any animals found to be incompletely thymectomised were discarded.

It can be seen in Table 1 that there was a marked delay in VOT in animals that had been thymectomised on day 2 (VOT 50.5 ± 1.4 d) compared with the untreated (VOT 35.1 ± 0.8 d) and sham-operated mice (VOT 34.8 ± 0.9 d). It is especially noteworthy that when thymectomy was performed on day 10, there was no delay in VOT (35.4 ± 1.4 d). Grafting the thymus into mice 3 d old and thymectomised 1 d earlier, counteracted the delay in the VOT (37.8 ± 1.5). In contrast to an intact thymus, the administration of 5×10^6 thymocytes did not influence the delay in the VOT in thymectomised 2-d-old mice (47.8 ± 2.8 d).

The sexual cycle, as reflected by vaginal cytology, showed that irrespective of thymic presence or lack of it, once the vagina had opened, the first oestrus appeared in all animals within 4 d. The cycles were entirely normal during the 15 d of observation.

Morphological studies in neonatally thymectomised mice revealed that before the delayed vaginal opening occurs, the ovaries and uterus are very small and display the typical

histological pattern characteristic of prepubertal immaturity.

What we have said of the thymectomised mice is also true of congenitally athymic female nude mice, the behaviour of which prompted us to investigate the thymectomised animals. Nude mice have a thymic anlage in the foetus but on day 14 of pregnancy it is already abnormal. The animals have a scarcity of lymphocytes in the paracortical area of lymph nodes and fail to reject allogeneic skin grafts[5].

Congenitally athymic female nude mice (*nu/nu* BALB/c) and their normal thymus-bearing female litter mates (BALB/c) were kept in specific pathogen-free (SPF) conditions until transfer to this laboratory. Some of the animals were bred and kept in germ-free conditions.

Data on athymic nude mice are given in Table 2. Vaginal opening time was also delayed in germ-free conditions.

The great difference in the size of the uterus and ovary between a 43-d-old athymic nude and a normal mouse is clearly shown in Fig. 1. Especially striking is the normalisation of these organs following thymus transplantation on day 2. By 10 d after VOT, the ovaries and uterus had already developed and presented an entirely normal appear- by increasing their residence times. Also that any appreance histologically.

To determine whether the thymus involvement in sexual maturation is dependent on its immunological function, newborn nude mice were injected intraperitoneally with 15×10^6 each of thymocytes (four animals); spleen cells (three animals); and lymph node cells (two animals) from adult BALB/c mice 3 months old.

Vaginal opening time was found to be delayed (VOT 49.1 ± 0.4 d). 1–2 weeks after VOT, the animals were transplanted with skin from C57 black mice. After 2 weeks, six out of nine nude mice injected with cells had rejected the skin grafts. Thus, it seems that whereas the injected lymphoid cells can establish cell-mediated immunity in the nudes, they cannot normalise sexual maturation.

Our findings indicate that the absence of the thymus in the early stages of life, as in Charles River mice thymectomised on day 2 and in congenitally athymic nude mice, causes a significant delay in puberty (as reflected in vaginal opening time and first oestrus) and a delay in the maturation of the ovaries and uterus. A few days after attainment of the VOT, a normal sexual cycle and normal uterus and ovary morphology are established. The fact that the same delay in sexual maturation occured in germ-free nude mice rules out the likelihood that in these immunodeficient animals, infection is involved in this phenomenon. Thymus grafts were able to speed up the onset of puberty provided they were implanted on the second or third day of life. Postponement of thymus implantation to day 10 no longer effected an acceleration of the sexual function. Furthermore, the injection of lymphoid cells into newborn nudes does not normalise sexual maturation. All these findings indicate a causal relationship between a functioning thymus and the normal development of sexual function in the female during the early stages of postnatal life.

Pfeiffer[6], showed that the pattern of sexual functions is established during the perinatal period. The presence or absence of the testicular hormone determines the future male or female rhythm of gonadotrophin release by the hypophysis (tonic or cyclic pattern). Current concepts[7,8] consider sexual hormones as at least partially responsible for the organisation of some of the central nervous system (CNS) control mechanisms which determine the activation of the sexual endocrine system in the adult.

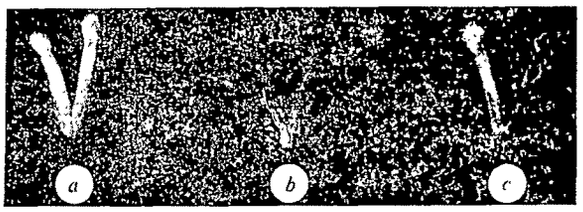

Fig. 1 Normalisation of sexual organ development by thymus. Gross appearance of uterus and ovaries of 43-d-old BALB/c mice (*a*), athymic nude mice (*b*), and athymic nude mice with a thymus graft (*c*). The thymus graft was made on animals 2 d old.

As the thymus has now been shown to influence the onset of the sexual functions, and as this effect is observed during the perinatal period, in which the CNS is being programmed, it is a reasonable assumption that the thymus is likewise involved in this process. The onset of puberty is a neuroendocrine phenomenon[9]; for this reason one can conceive of the thymus exerting its influence by the elaboration of hormones that could either act directly on the CNS or indirectly through endocrine glands. These hormonal influences of the thymus may be greatest during the perinatal period, when this organ is known to be more crucial than in later life.

Table 2 Delay in vaginal opening time in congenitally athymic nude mice (*nu/nu* BALB/c) and restoration by early thymus grafting

The delay in puberty in mice without thymus glands can provide an explanation for the persistence of the reticular zone of the adrenals in nude mice[3] because this zone tends to disappear after puberty.

Nishizuka and Sakakura[10–12] have observed earlier ovary dysgenesis (lack of follicles and of corpora lutea) and hyperplasia of the interstitial cells in about 50% of neonatally thymectomised female mice. This work, however, was not concerned with sexual development, because, depending on the strain studied, the dysgenesis was not observable before 60–120 d of age, a time when puberty had already occurred and normal sexual cycles were well established. This ovarian dysgenesis was prevented by spleen or thymus grafts and by lymphoid cell injection given during the first days of life. These experiments were performed in animals maintained in conventional conditions. As the administration of lymphoid cells and thymus or spleen grafts (which can restore immune functions) prevented the ovarian dysgenesis, the results obtained by these authors could have been influenced by intercurrent infection and might reflect an early manifestation of wasting disease or express some lymphoid cell function. Whichever of these possibilities apply, this situation can hardly involve an endocrine thymic function.

It has been demonstrated that the thymus is involved in the complex endocrine mechanisms controlling sexual development during a critical period of life, presumably by an elaboration of hormonal factor, as immunocompetent cells can not compensate for thymus absence, as far as sexual maturation is concerned. Such thymus involvement in sexual function has been suspected earlier as reviewed by Hammar[13]. In as much as the thymus is involved in the onset of puberty, and thymus involution also begins at this time, this would seem to indicate that a feedback mechanism is in operation.

We thank Dr H. Hurni and Gisela Hämmerli, Ciba-Geigy, Sisseln, for their help and observation in the germ-free animals and Anna Arcon for technical assistance. Sir Peter Medawar and Dr M. Landy criticised the manuscript. The congenitally athymic female nude mice (*nu/nu* BALB/c) and their normal thymus-bearing female littermates (BALB/c) were purchased from Dr C. W. Friis, GI. Bomholtgård, Ry, Denmark. This work was supported by a grant from the Schweizerischer Nationalfonds zur Förderung der wissenschaftlichen Forschung. H. B. is the recipient of an Argentine National Research Council fellowship.

Evidence for non-identity of T killer and T helper cells sensitised to allogeneic cell antigens

Bone marrow-derived lymphocytes (B cells) can be triggered for antibody synthesis by a stimulus from immunocompentent allogeneic[1] or xenogeneic[2] lymphoid cells. The stimulus was shown to act directly on the B cell, since a response may occur in the absence of syngeneic thymus-derived lymphocytes (T cells)[1] and is possible even to a hapten[2]. This observation has led to the hypothesis that cooperating T cells (T-helper) are identical to cytotoxic T cells (T-killer) and act on B cells by surveying them for immunogen bound to their cell surface[3]. The T cells recognise the cell-bound immunogen and emit a sublethal signal to the B cells, triggering them to produce antibody. But the question arises, whether this is the way triggering of B cells usually occurs in the immune response. Recent experiments have shown that T cells sensitised to foreign erythrocyte antigens are able to cooperate with B cells to induce humoral antibody synthesis, but are not able to perform cytotoxic lysis of erythrocyte target cells[4,5]. T helper cells therefore need not be cytotoxic to the sensitising antigen to trigger B cells. This finding led to more extensive experiments concerning the question of whether T killer and T helper functions are performed by the same cell or not.

I shall show here that T helper and T killer cells sensitised to the same immunogen are not likely to be identical, because they are found to be mutually exclusive under certain immunisation conditions.

The DBA/2J mastocytoma P185 injected into C57BL/6J mice has been shown to induce cytotoxic effector cells as well as humoral antibody synthesis[6,7]. For both of these responses, T cells are necessary: T killer cells act as cytotoxic effectors[6] and T helper cells trigger B cells for antibody synthesis. This model therefore seemed to be suitable to explore the relation of T helper and T killer cells. I set up experiments to find immunisation procedures which favour the appearance of either T killer or T helper activity in the spleen. Since it had previously been shown that treatment of erythrocytes with formaldehyde or glutaraldehyde inhibits the humoral immune response to such treated immunogen, without affecting the priming of T helper cells[8], P815 cells were fixed in the same way. P815 cells treated with formaldehyde or glutaraldehyde (F-P815 and G-P815) were injected into C57BL/6J mice and their spleens assayed for cytotoxicity after 9 d. It is seen from Table 1 that F-P815 and G-P815 cells are not able to induce cytoxicity in C57BL/6J splens, while normal P815 cells do so.

To find out whether one or the other of such immunised spleen cell preparations contain T helper cells, the same spleen cell preparations were incubated in Mishell Dutton type cultures[9] together with trinitrophenyl-coupled[10] P815 cells (TNP-P815) as antigen. Table 1 shows that while F-P815 and G-P815 primed spleens vigorously stimulate the TNP response, cytotoxic P815 primed spleens do not. This result could have various explanations: it may be that P815 primed spleen cells are not able to respond to *in vitro* antigen stimulation. But in other experiments it was shown that P815 primed spleen cells respond as well as, or even better than, normal or F-P815 primed spleen cells to sheep red blood cell antigens *in vitro* (unpublished results).

Another possibility could be that P815 primed spleen cells do contain P815 specific T helper cells but these helper cells do not display their activity, maybe because they are not at the proper concentration in these spleens. To check this, cytotoxic P815 primed spleen cells were mixed in varying proportions with normal spleen cells and assayed for carrier priming. Table 2 demonstrates that also under these conditions no helper function can be detected in cytotoxic spleens. Cytotoxic spleens therefore seem to contain no

Table 1 Induction of cell-mediated cytotoxicity and helper activity by normal and fixed P815 cells

2×10^7 F-P815	—	—	+	196

C57BL/6J mice were injected with varying doses of normal and fixed P815 cells intraperitoneally (i.p.) on day −11. DBA-2 mastocytoma cells P815 were grown in Dulbecco's modified MEM supplemented with 10% calf serum and fixed with 1.5% formaldehyde, 0.25% or 0.025% glutaraldehyde exactly as previously described for erythrocytes[8]. *In vitro* cytotoxicity assay: spleen cells of immunised mice were assayed for cytoxicity using ^{51}Cr-labelled P815 target cells as described previously[5,6]. Attacker to target cell ratio was 100:1. Percentage cytotoxicity (over spontaneous release) is calculated from the ratio of released counts to that released after three times freeze thawing[5]. *In vitro* helper activity assay: spleen cells were incubated in Mishell Dutton type cultures[9] with 10^6 TNP-P815 cells per culture. TNP-P815 cells were prepared as described for erythrocytes by Rittenberg and Pratt[10] and subsequently irradiated with 5,000 r. The TNP response was assayed on day 5 on TNP-BRBC[9,10].

helper activity as assayed with TNP-P815 antigen *in vitro*. This finding is somewhat surprising since it had previously been shown that in mice injected with P815 cells antibody production can be detected[7]. T helper cells therefore should at least at some time be operative during the *in vivo* immune response to P815.

Another possibility could be that the helper cells in cytotoxic spleens are not detected, because their activity is suppressed by a population of suppressor cells like those described by Jacobson and Herzenberg[11]. To find out, cytotoxic spleens and carrier-primed spleens were mixed and assayed for helper activity. It is seen in Table 3, experiment 1, that cells from cytotoxic spleens suppress the helper activity of F-P815 primed spleens, either partially (Table 3) or completely (unpublished results). It is therefore not surprising that helper activity cannot be detected in cytotoxic spleens using this assay. The question arises: why do live P815 cells prime for both killer and suppressor activity but not for helper activity, while fixed P815 cells prime only for helper but not for killer and suppressor activity? Though it is tempting to speculate that the cytotoxic T cells are the cells which suppress the function of the helper cells, this has to be shown by further experiments.

Carrier priming for erythrocyte antigens is known to be especially effective with low doses of antigen[8,12]. Since fixation of P815 cells with formaldehyde destroys about 95% of the H-2d antigenic determinants on P815 cells (R. Hyman and G. Dennert, unpublished results), it is possible that carrier priming with fixed P815 cells is in fact a low dose priming insufficient to prime T killer cells. If this reasoning is correct, then low doses of normal P815 cells should also prime for helper activity. Table 4 shows that this is the case. P815 cells were irradiated with 2,000 r. to inhibit multiplication and injected in various doses into animals. It is seen that helper activity is found in spleens injected with low doses (2×10^6 and 4×10^5 P815 cells per mouse) but not in mice injected with a higher dose (10^7) of P815 cells. The latter dose was also insufficient to induce cytotoxic T cells in these mice and it was subsequently found that ten times higher doses of irradiated cells have to be injected to prime for T killer cells (unpublished results). These experiments therefore seem to support the idea that carrier priming by fixed P815 cells is actually due to a low dose priming. Priming with fixed P815 cells however is usually superior to priming with low doses of normal P815 cells. This was also found in experiments where carrier priming to normal and fixed erythrocytes was studied[8].

Though it had previously been shown[6] that cytotoxicity of

Table 2 Failure to detect carrier priming in mixtures of P815 primed spleen cells and normal spleen cells

P815	5×10^3	+	—	35
P815	5×10^3	+	+	27

C57BL/6J mice were immunised with 10^7 F-P815 or 10^7 P815 cells i.p. on day −11. Spleen cells were collected and tested for cytotoxicity. Spleens primed with P815 showed 62% cytotoxicity at $t=4$ h at an attacker to target cell ratio of 100:1, spleen cells primed with F-P815 had no detectable cytotoxicity. Aliquots of spleen cells were cultured with TNP-P815 cells as antigen. P815 primed spleen cells were also mixed in various ratios with normal spleen cells. The plaque assay was done on day 5.

Table 3 Inhibition of helper activity by cytotoxic spleen cells and anti-θ serum treatment

F-P815 immune+C′	+	132

Experiment 1: C57BL/6J mice were primed with 5×10^7 F-P815 cells or 10^7 P815 i.p. on day −9. Helper activity was assayed as in Table 1. Experiment 2: C57BL/6J mice were immunised with 5×10^7 F-P815 cells on day −9 and spleens asssayed for helper activity. For anti-θ serum treatment[13] 2×10^7 spleen cells were incubated in 1 ml BSS and 0.1 ml anti-θ serum for 30 min at 0° C. Cells were washed and resuspended in 1 ml BSS containing 0.15 ml guinea pig complement[5] and incubated 30 min at 37° C. Controls were incubated with complement only.

Table 4 Carrier priming by fixed and normal P815 cells

In vivo immunogen	10^6 TNP-P815 per culture	P.F.C. per 10^6 on TNP-BRBC
—	—	1
—	+	< 1
5×10^7 F-P815	—	35
5×10^7 F-P815	+	446
10^7 P815 2,000 r.	—	3
10^7 P815 2,000 r.	+	< 1
2×10^6 P815 2,000 r.	—	11
2×10^6 P815 2,000 r.	+	54
4×10^5 P815 2,000 r.	—	9
3×10^5 P815 2,000 r.	+	102

C57BL/6J mice were injected with varying doses of F-P815 and normal P815, irradiated with 2,000 r. On day 11, spleens were collected and tested for cytotoxicity and carrier priming. None of the groups showed any cytotoxic activity in their spleens.

P815 immunised C57BL/6J spleen cells is effected by thymus-derived lymphocytes, it had to be demonstrated that the helper activity observed in F-P815 primed spleen cells is also due to T cells. Treatment of F-P815 primed spleens with anti-θ serum[13] and complement completely abrogated the helper activity of these spleens, confirming that this activity is mediated by thymus-derived lymphocytes (Table 3, experiment 2).

In summary, these experiments show that under appropriate immunisation conditions either helper T cells or killer T cells can be found in sensitised spleens: spleens which show helper activity are not cytotoxic and spleens which are cytotoxic show no helper activity. Since it is found, however, that cytotoxic spleens inhibit the helper activity of F-P815 primed spleen cells it cannot be excluded that cytotoxic spleens contain T helper cells.

The experiments do not show that low doses of irradiated P815 or F-P815 prime directly for T helper cells for the following reason: the T helper assay *in vitro* takes 5 d of incubation, while the cytotoxic assay takes only a few hours. Thus, in culture maturation of a T helper precursor to T helper could occur. These experiments, however, strongly argue that the helper cell (or the precursor thereof) and the cytotoxic killer cell are likely to be two different subsets of T cells.

Recently other subsets of T cells with specific functions have been described[14]. Cantor and Asofsky demonstrated the requirement of two cells with different sensitivities to anti-thymocyte serum in a graft-*versus*-host reaction[15]. Bach *et al.*[16] demonstrated the existence of two populations of cells, one responding in the mixed lymphocyte reaction and the other effecting cell mediated lysis. It is therefore not surprising that T helper and T killer cells are found here to be different cell types. Further experiments must be directed toward determining the relationships between the various subsets of T cells so far described.

I thank R. Austin for assistance and Dr Edwin S. Lennox for discussion and financial support. Funds were provided by a grant from the National Institutes of Health to Edwin S. Lennox, and from The Edna McConnell Clark Foundation, The Korda Foundation, and The American Cancer Society.

Type-specific protein in herpes simplex virus envelope reacts with neutralising antibody

CERVICAL carcinoma has been correlated with previous infection with herpes simplex virus type 2 detected serologically[1-3]. These tests have, however, been confused by the fact that type 1 and type 2 herpes simplex viruses cross neutralise and it is therefore difficult to use the data to provide clear evidence for previous type 2 infection[4]. We have previously shown that antisera to types 1 and 2 viruses contain antibodies to a structural antigen, Band II (ref. 5), which neutralise both types of virus[6]. By indirect absorption methods, we have shown that they also contain antibodies to type-specific proteins which neutralise the homologous type only[6].

We now present more direct evidence for the existence of such proteins by showing that antiserum to a glycoprotein of enveloped type 1 virus particles neutralises type 1 but not type 2 virus. These studies indicate that it should be possible to prepare type-specific antigens which could be used in seroepidemiological surveys to provide conclusive evidence of previous type 2 infection.

Enveloped particles of herpes simplex virus type 1 were obtained by precipitation by polyethylene glycol of the virus released into the supernatant growth medium of HEP 2 cells infected with herpes simplex type 1 (strain HFEM). The virus was purified by two cycles of sedimentation in sucrose gradients. Figure 1 shows the pattern of polypeptides revealed by electrophoresis in SDS polyacrylamide gels of the purified virus after disruption with SDS and dithiothreitol. The region marked VP2/3 has been shown to correspond to glycosylated polypeptides not present in naked virus particles (K.L.P., and D.H.W., unpublished). A longitudinal slice was removed

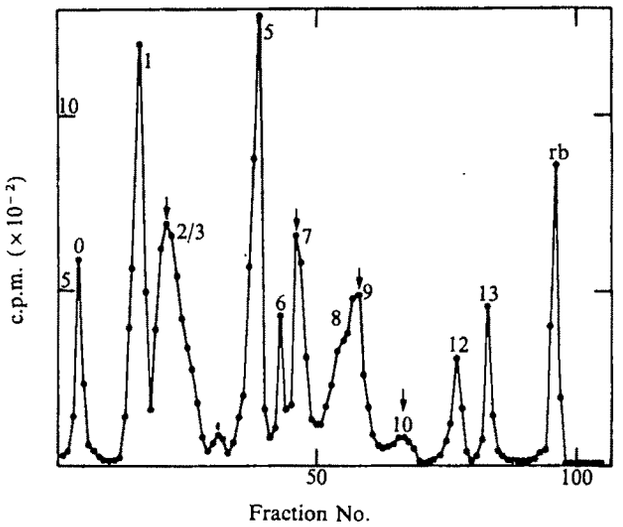

Fig. 1 Electrophoresis of disrupted enveloped Herpes simplex virus particles on SDS-polyacrylamide gel. Direction of migration from left to right (that is, higher molecular weight polypeptides to the left). Peaks identified as glycoproteins by glucosamine labelling are arrowed. Peak 1 is the major capsid polypeptide corresponding to VP5 of Spear and Roizman[8] and peak 2/3 (VP2/3) most likely corresponds to their broad glycoprotein peak VP7/8.

from other gels to identify the VP2/3 region and the appropriate segments removed from the remaining portion of the gels. The segments were macerated and injected with Freund's incomplete adjuvant into the footpads of rabbits. From the intensity of stain in the gel slices we estimate that about 40 μg protein was inoculated. A second injection was given 2 weeks later and the rabbits bled after a further 10 d.

The resulting antiserum was tested in neutralisation tests against herpes simplex type 1 strain HFEM and herpes simplex type 2 strain 3345 as previously described[6]. The neutralisation rate constant against type 1 virus was 0.167 (mean of seven determinations) and against type 2 virus was 0.001 (mean of nine determinations) which did not differ significantly from zero. In contrast, antiserum to Band II had neutralisation rate constants against type 1 virus of 0.18 and against type 2 virus of 0.06 (ref. 6). The neutralising activity of the antiserum to VP2/3 was unaffected by absorption with an extract of cells infected with herpes simplex virus type 2, but was completely abolished by absorption with an extract of cells infected with herpes simplex virus type 1. The neutralisation rate constant of antiserum to Band II antigen, however, was reduced by 90% after absorption with the same extract of cells infected with type 2 virus (Table 1).

Table 1 Proof of type specificity of antiserum to VP2/3 polypeptide by absorption tests.

Antiserum	Absorbed with	Neutralisation rate constant of absorbed serum for type 1 virus
Anti VP2/3	Extract of uninfected cells	0.120
Anti VP2/3	Extract of cells infected with type 1 virus	0
Anti VP2/3	Extract of cells infected with type 2 virus	0.132
Anti Band II	Extract of uninfected cells	0.644
Anti Band II	Extract of cells infected with type 1 virus	0
Anti Band II	Extract of cells infected with type 2 virus	0.052

The antiserum to VP2/3 had similar neutralisation rate constants in tests against two other type 1 strains but gave no significant neutralisation of two other type 2 strains. The type specificity was confirmed by complement fixation tests (Table 2).

Table 2 Type specificity of antiserum to VP2/3 polypeptide demonstrated by complement fixation

Antiserum	Complement fixing titre* with	
	Type 1 antigen	Type 2 antigen
Anti-VP2/3	1280	<40†
Anti-type 1 virus	2560	5120
Anti-type 2 virus	2560	2560

* Reciprocal of highest dilution fixing 1.5 units of complement using optimum dilutions of antigens.
† Antiserum had anticomplementary activity at lower dilutions.

An antiserum with similar neutralising properties was obtained by an alternative method. Antiserum to type 1 virus, rendered selective for type-specific antigens by absorption with an extract of type 2 virus-infected cells[6], was used to detect type-specific antigens in fractions obtained by preparative polyacrylamide gel electrophoresis (without SDS) of an infected cell extract[7]. Precipitin bands obtained in agar gel immunodiffusion of one type specific fraction and the antiserum, were injected into the footpad of rabbits. This antiserum and antiserum to VP2/3 gave single precipitin bands in agar gel immunodiffusion tests with extracts of cells infected with type 1 virus. The precipitin bands obtained with the two antisera showed reaction of identity. Neither antisera gave any reaction in immunodiffusion tests with extracts of cells infected with type 2 virus.

The results provide direct evidence for the presence of a type-specific antigen both in infected cells and as a glycoprotein on the surface of enveloped particles, whose interaction with its corresponding antibody leads to a loss of virus infectivity. They offer some hope that it may be possible to prepare a type-specific reagent for detection of previous type 2 infection in seroepidemiological surveys.

We thank the Medical Research Council for a research grant, and the Science Research Council for a research studentship (K.L.P.).

Received January 14, 1974.

Note added in proof: Since this work was completed we have heard that Dr R. J. Courtney (Baylor University College of Medicine, Houston, Texas) has prepared an antiserum with similar properties using extracts of cells infected with herpes simplex virus type 1. This antiserum also had type specific neutralising activity.

In vitro generation of B lymphocytes in mouse foetal liver, a mammalian 'bursa equivalent'

THERE is good evidence that in birds a haemopoietic stem cells of yolk sac origin[1,2] differentiate into immunoglobulin-bearing lymphocytes in the bursa of Fabricius[3]. The differentiated lymphocytes then migrate to the peripheral lymphoid tissues[4,5], where they constitute the bursa-derived B lymphocyte population. The primary site(s) of B lymphocyte development in mammals, however, has remained a mystery, with gastrointestinal associated lymphoid tissues[6] (including appendix[7], tonsils[8] and Peyer's patches[9]) and haemopoietic tissues[10–12] generally considered the main candidates for mammalian 'bursa equivalent'. Here we report the development of IgM, IgG and probably IgA-bearing lymphocytes in organ cultures of mouse foetal liver removed at 14 d gestation, a time well before immunoglobulin-bearing cells or cells of lymphoid morphology could be detected in the intact animal. These studies indicate that foetal liver is a bursa equivalent in mice and that gastrointestinal lymphoid tissues are not a *sine qua non* for the initial development of B cells. In addition, they provide evidence that IgG and probablv IgA-bearing B lymphocytes can develop in the absence of T lymphocytes.

Foetal livers were removed from BALB/c embryos of 14 or 15 d gestation (the day of appearance of a vaginal plug being taken as day 0) and chopped with fine knives. Small explants (2–4 mm diameter) were placed on ultrathin Millipore filters (type TH), floating on 1 ml of RPMI 1640 medium containing 10% heat-inactivated foetal calf serum in the centre well of Falcon organ culture dishes (catalogue No. 3010), the outer trough being filled with distilled water. The dishes were incubated at 37°C in an atmosphere of 5% CO_2 in air. Foetal livers, spleens or cultured explants were

Table 1 Properties of fluorescein-conjugated antibodies

Antiserum	Abbreviation	Fraction used	F/P Ratio	Concentration used (mgml^{-1})	References	Proportion of cells labelled in adult spleen (%)

*See legend to Table 2.

taken at various times and teased in veronal-buffered saline containing 20% foetal calf serum and 0.2% sodium azide. Aliquots of cells were spun onto slides in a cytocentrifuge and stained with McNeal's tetrachrome. In addition, cells were incubated in suspension with a variety of fluorescein-conjugated antisera (see Table 1) at 0°C for 30 min, washed twice and examined for surface fluorescence using a modified Vicker's M40 microscope equipped for incident illumination as previously described[13]. Fluorescein-conjugated anti-immunoglobulin antibodies, polyspecific and class specific, were used to detect B lymphocytes[14] while a fluorescein-conjugated anti-θ serum was used to detect T cells[15]. All of these reagents have been used in previously reported experiments and their properties are outlined and referenced in Table 1. Usually the antibodies used were purified and absorbed using solid-phase immunoadsorbents. The proportion of cells labelled with the various reagents in adult BALB/c spleens is indicated in Table 1.

Differential cell counts on cytocentrifuge preparations from freshly teased (uncultured) tissues showed that most of the cells prepared from 12–19 d foetal liver belonged to the erythroid cell series. From 16 d, increasing numbers of granulocytic and monocytic cells were seen with the first lymphoid cells being detected at 17 d. We could distinguish lymphocytes from erythroid cells because lymphocytes have a thinner rim of cytoplasm which is paler staining than that of the erythroid series of cells. The picture in foetal spleen was similar to that in liver except that a greater proportion of granulocytic and monocytic cells were present at all stages. By fluoresence, immunoglobulin-bearing cells were first detected at 17 d gestation in both liver and spleen (Table 2) correlating well with the morphological studies. As has been shown in man[16], IgM and IgG-bearing cells developed before IgA-bearing lymphocytes. It seems that B cell development is relatively retarded in BALB/c mice compared to other strains where B cells have been detected

at 16 d gestation[11,17]. In agreement with this we have found that CBA mice have a higher proportion of B cells in their spleens at birth than do BALB/c mice.

Results of 14 d foetal liver organ culture experiments are outlined in Table 3. Although no cells of lymphocyte morphology were found in 14 d livers, after 4 d in culture approximately 0.5% of the nucleated cells were typical small lymphocytes on morphological criteria. With time in culture, erythopoiesis declined and an increasing percentage of the cells present were granulocytic, monocytic and lymphoid, with approximately 2–3% of the cells being lymphocytes after 7 d in culture. Correlating well with the morphological studies, 0.2–0.45% of cells from explants in culture for 4 d bore immunoglobulin, mostly IgM, with a smaller proportion of IgG_2-bearing cells. The proportion increased with time in culture, so that at 7 d between 2–3% of the cells were immunoglobulin-positive, and two cells (out of 4000 scanned) were found that stained distinctly, but faintly, with anti-α-fluorescein(fl). No cells labelled with anti-θ-fl, anti-γ_1-fl or anti-human-μ-fl after 4 or 5 d in culture, while an appropriate proportion labelled with Fab anti-MIg-fl, excluding the possibility that fluorescent labelling was related to the binding of the conjugates by Fc receptors of cells and indicating that θ-bearing T cells did not develop in these cultures.

It is highly unlikely that the immunoglobulin-bearing cells detected after 4 d in culture were present in the 14 d liver explants at the beginning of the culture period and then merely concentrated by selective cell survival, as no immunoglobulin-bearing cells were detected in scanning more than 0.4×10^6 cells from 14–16 d livers, including samples from all livers that were subsequently cultured. Although there was a selective loss of erythroid cells during culture, we were able to collect 3×10^5–6×10^6 cells following 4–7 d culture of 2 or 3 14 d livers (about 3×10^7 can be collected by teasing from this number of livers). Even with this cell loss, if the B cells which we detected after culture (up to 3% of the cells collected) were already present before culture, we would have detected them among the large number of 14 d foetal liver cells examined.

These experiments show that immunoglobulin-bearing B lymphocytes can differentiate within mammalian foetal liver, *in vitro*. On this basis mammalian foetal liver can be considered as a possible candidate for a mammalian 'bursal equivalent'. We believe that the liver provides a 'micro-environment' for B cell differentiation as we failed to find immunoglobulin-bearing cells in 5 d cultures of liver cells obtained from 14 day foetal liver either by trypsinisation or by gently teasing the tissue apart. The cells were cultured in Falcon flasks in exactly the same media and atmosphere as adopted for the whole organ culture. The possibility that B cells can also develop in other tissues, such as the appendix and Peyer's patches, has not been excluded, although the intestinal epithelial theory of B cell maturation[6,18,19] is no longer tenable in its original form. It will be of interest to investigate the capacity of other tissues, such as foetal spleen and bone marrow, to generate B cells *in vitro*, to determine if all haemopoietic tissues can serve this function, or whether foetal liver, which is largely derived from foregut epithelium, is the only bursa-equivalent organ. These experiments also demonstrate that IgM, IgG and probably IgA-bearing cells can develop in the foetal liver, in the absence of T cells, providing the most direct evidence thus far that T cells are not required for the postulated switch from IgM to IgG and/or to IgA in single B cells[20–23]. The failure of θ-bearing T lymphocytes to develop in 5d cultures is of interest in view of the recent evidence that agents such as poly(A)·poly (U), cyclic AMP and lipopolysaccharide can induce some cells in 14 d foetal liver to express θ (ref. 24). Our attempts, in collaboration with Peter Beverley, to induce the appearance of immunoglobulin-or θ-bearing cells during a 2 h incubation of 14 d BALB/c foetal liver cells with these agents have failed so far.

The development of B lymphocytes in 14 d foetal liver explants should provide a useful system for investigating the microenvironmental requirements for B cell differentiation, the putative immunoglobulin class switch, tolerance induction, and the generation of antibody diversity in the absence of T cells and in a relatively controlled antigenic environment. Elucidation of the bursa equivalent is of obvious importance to the understanding of a variety of immune deficiency diseases.

Expression of M locus differences by B cells but not T cells

Within or close to the major histocompatibility complex (MHC) of man and mouse there are genetic loci which control the production of lymphocyte-associated determinants capable of stimulating allogeneic lymphocytes to synthesise DNA in

Table 1 MLR between cells from MHC and M different mice

Responder	Stimulator					
	CBA/J spleen	CBA/J thymus	C3H/HeJ spleen	BALB/cJ spleen	DBA/2J spleen	DBA/2J thymus
CBA/J thymus	4,167 ± 503	—	4,251 ± 306	19,194 ± 2701	—	—

Numbers represent c.p.m. ± s.d.

mixed lymphocyte culture[1,2]. In the mouse the mixed lymphocyte reaction (MLR) is also controlled by an additional locus, the M locus, which is not linked to MHC[3]. These MLR loci seem to be distinct from the loci coding for serologically defined (SD) antigens[1,2,4]. Recent studies suggest that, in certain situations, a genetic difference between responder and stimulator cells is not an absolute requirement in MLR. Thus, Howe *et al.*[5] and Boehmer *et al.*[6,7] found that thymus cells from certain mouse strains produce high levels of thymidine incorporation when cultured with syngeneic B lymphocytes.

Lymphocytes which proliferate in response to cells differing at lymphocyte defined (LD) loci, but not at SD loci, are reported to be unable to develop into cytotoxic effector cells[1,2,4]. The nature of the LD stimuli which induce cell proliferation in this situation is unknown. This paper attempts to define the cells which carry these determinants.

We have employed Hannig's system of preparative cell electrophoresis[8] to prepare highly purified T and B cell populations for use as stimulating cells in MLR. BALB/c ($H2^d$, Mls^b), DBA/2 ($H2^d$, Mls^b), C3H ($H2^k$, Mls^c) and CBA/J ($H2^k$, Mls^d) mice were used in these studies. BALB/c and DBA/2 are MHC identical but differ at the M locus; a similar relationship exists between C3H and CBA/J.

Thymus cells, thoracic duct lymphocytes (TDL) and spleen cells were obtained by standard methods[9]. TDL were used as stimulating cells after separation by electrophoresis as described previously[10]. Thymocytes from 6-week-old mice served as responder cells. These cells were cultured with stimulator cells treated with mitomycin C[11] from thymus, spleen or TDL in Falcon plastic tubes 2005 (Gateway International, Los Angeles) at a total cell concentration of 5×10^6 per ml culture medium. With thymus cells as stimulators, the ratio of responding to stimulating cells was 3 : 1; with cells from spleen and TDL, a responder : stimulator ratio of 10 : 1 was chosen; in previous studies these ratios gave optimal stimulation with strain combinations differing at the MHC or M locus and reduced 'backstimulation' (see below) by the mitomycin C-treated cells (ref. 12 and unpublished observations). The culture medium used was RPMI 1640 supplemented with 10% foetal calf serum and mercaptoethanol[13]. The cells were cultured at 37° C in a humidified atmosphere of 10% CO_2 in air. ^{3}H-thymidine (Radiochemical Centre, Amersham, specific activity 25 Cimmol^{-1}) was added to the cultures at a final concentration of 1.3 μCiml^{-1} after 48 h and cells were collected after 60 h. Radioactivity in DNA extracted from the cells was measured as described previously[11]. Background thymidine incorporation was calculated from separate incubations of either 5×10^6 responder or stimulator cells.

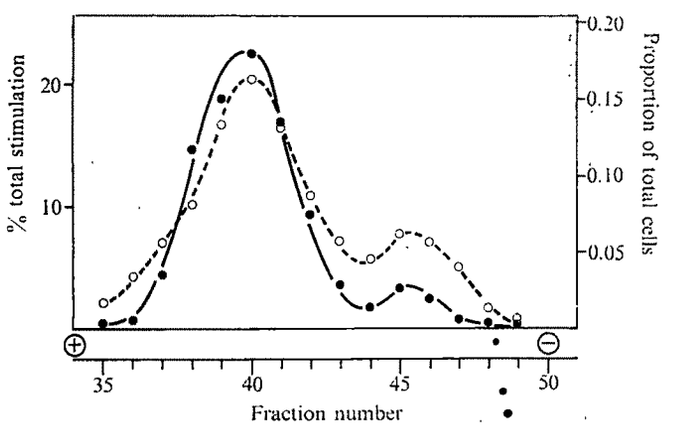

Fig. 1 Stimulating capacity of electrophoretically separated CBA TDL treated with mitomycin C cultured with BALB/c (MHC plus M different) thymus cells. Calculated background: 1,371 c.p.m. Peak stimulation with 5×10^5 stimulators: 103,428 ± 5,630 c.p.m. ●—●, Stimulation; ○--○, all cells.

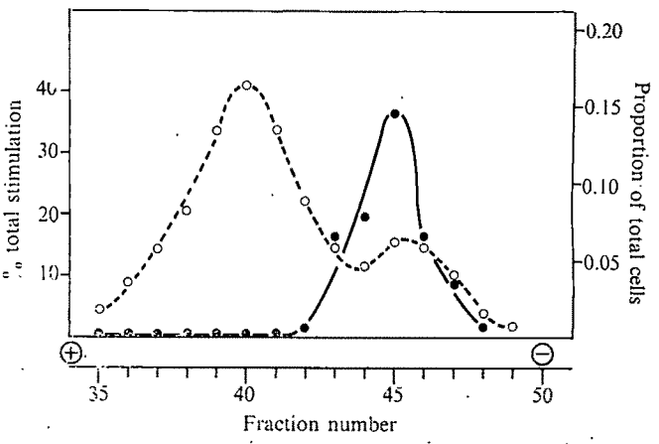

Fig. 2 Stimulating capacity of electrophoretically separated CBA TDL treated with mitomycin C cultured with C3H (M different) thymus cells. Calculated background: 2,528 c.p.m. Peak stimulation with 5×10^5 stimulators: 42,679 ± 3,926 c.p.m. ●—●, Stimulation; ○--○, all cells.

Table 1 shows DNA synthesis by thymus cells cultured with stimulating cells from various sources. It is apparent that there is undirectional stimulation of BALB/c thymus by DBA/2 spleen and of C3H thymus by CBA spleen. These findings are in agreement with the studies of Festenstein[14] and Salaman *et al.*[15]. They differ to some extent from the findings of Katz-Heber *et al*[16]. These workers found that while BALB/c cells responded strongly to DBA/2, a significant though weak response was also observed in the reverse direction. The authors used a low ratio of responder to stimulator cells in their cultures. Recent work of one of us (H.v.B.) suggests that, under these conditions, the response observed by Katz-Heber *et al.* when BALB/c cells were used as the stimulating population might have reflected 'backstimulation' of the DBA/2 cells. In this respect, significant DNA synthesis was observed when parental cells treated with mitomycin C were cultured at a low (but not a high) ratio with semiallogeneic F_1 hybrid cells. From additional evidence it was concluded that DNA synthesis in this situation represented backstimulation of F_1 cells responding to a 'recognition signal' from the T cells in the parental population treated with mitomycin C[17,18].

When thymus cells instead of spleen cells were used as stimulators, responses by thymus cells were significant when an MHC difference was involved but not significant when the cells differed at the M locus only (Table 1). The data in Table 1 suggest, therefore, that the lymphocyte-defined differences coded for by the M locus were carried by spleen cells but not

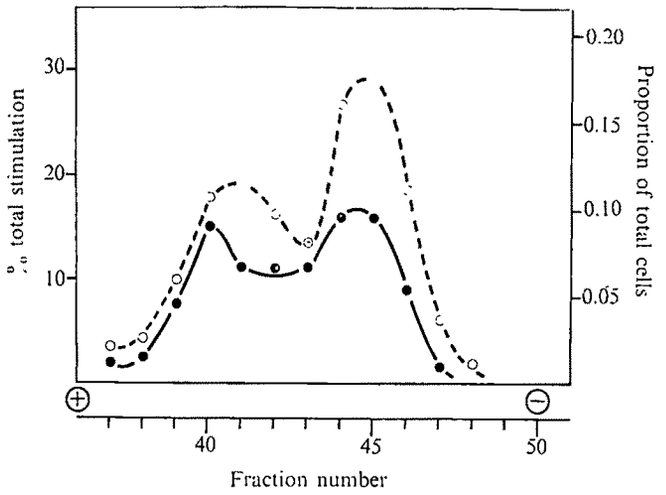

Fig. 3 Stimulating capacity of electrophoretically separated DBA/2 TDL treated with mitomycin C cultured with CBA/J (MHC plus M different) thymus cells. Calculated background: 3,049 c.p.m. Peak stimulation with 5×10^5 stimulators: 41,683 ± 1,050 c.p.m. (DBA/2 TDL were obtained 48 h after cannulation and have therefore a higher proportion of B lymphocytes.) ●—●, Stimulation; ○ – – ○, all cells.

by thymus cells. More precise information on this point was obtained by testing the stimulating capacity of purified populations of mature (small) T and B lymphocytes obtained from thoracic duct lymph.

TDL subjected to electrophoresis separate into two distinct cell populations which partly overlap[19]. Previous studies showed that T (θ positive) and B (immunoglobulin positive) lymphocytes were arranged in Gaussian distribution in the fast moving and slow moving cell fractions, respectively. Thus the fractions of highest electrophoretic mobility consisted of pure T cells and the fractions of lowest electrophoretic mobility of pure B cells; intermediate fractions contained both T and B lymphocytes.

Electrophoretically separated cell fractions of TDL from CBA mice were treated with mitomycin C and cultured separately at a ratio of 1:10 with thymus cells differing at the M locus (C3H) or at both MHC and M locus (BALB/c), The stimulation observed in these cultures is shown in Figs 1 and 2. As described elsewhere[18], the data are expressed as the proportional stimulation provided by each stimulator fraction. To make this calculation, the counts above background given by the aliquot (0.5×10^6 cells) of each fraction of stimulating cells was

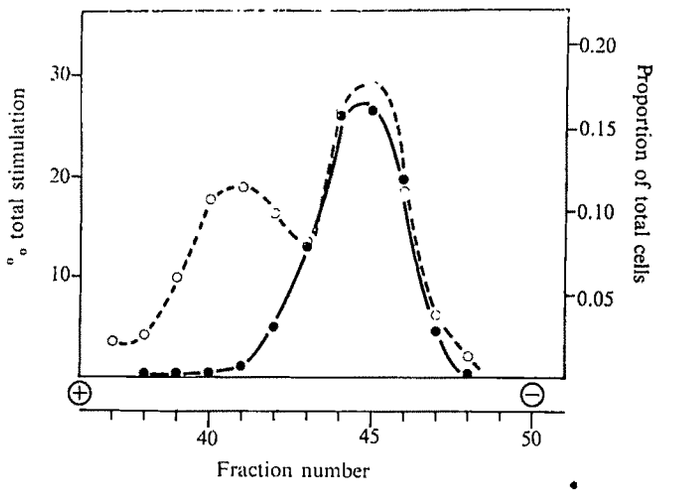

Fig. 4 Stimulating capacity of electrophoretically separated DBA/2 TDL treated with mitomycin C cultured with BALB/c (M different) thymus cells. Calculated background: 1,537 c.p.m. Peak stimulation with 5×10^5 stimulators: 66,003 ± 9,803 c.p.m. ●—●, Stimulation, ○ – – ○ all cells.

multiplied by the total number of cells in that fraction. Under the constant culture conditions used, addition of the values obtained for each cell fraction provided an estimate of the total stimulating capacity of the TDL populations as a whole. The proportional stimulation provided by each fraction was then calculated with reference to this combined value.

When the data are expressed in this fashion, it is evident that, with MHC differences, thymus cells responded to TDL fractions containing either T cells, B cells or mixtures of T and B cells to approximately the same extent. With a difference restricted to the M locus, by contrast, thymus cells responded only to cells from fractions containing B cells. Similarly, fractions B cell-depleted of DBA/2 TDL stimulated CBA (MHC plus M different) thymus but not BALB/c (M different) thymus (Figs 3 and 4).

The observation that T and B lymphocytes share the capacity to induce allogeneic (MHC different) T cells to synthesise DNA corroborates our previous findings[17,20]. A consensus of opinion has yet to be obtained on this point, however, since some workers have claimed that the allogeneic stimulus is carried predominantly by B cells[19], though others maintained it was only found on T cells[21]. The failure of these workers to use more precisely defined populations of T and B cells in their studies might have contributed to the disparity in their results.

We do not know the significance of the finding that, in the MLR, the stimulus to lymphocytes differing solely at the M locus is carried exclusively by B lymphocytes. As mentioned previously, B lymphocytes activated solely by M locus differences were reported to be unable to induce cell-mediated lympholysis (CML) (ref. 4). Phytohaemagglutinin (PHA)-transformed blasts were used as target cells for CML in this study. Our work questions the validity of this choice of target cells. Thus, in mice, PHA blasts are considered to be derived from T cells that is from cells which in our studies did not express detectable M locus differences. For this reason work is currently in progress in our laboratory to determine whether lymphocytes activated to LD differences can lyse B blast cells.

We thank Nancy Erhardt for technical help.

Erythropoiesis in an avian thymus

As part of an ecological study of the red billed quelea, *Quelea quelea*, undertaken in Tanzania and Kenya between 1969 and 1972, the size and colour of the thymus glands in over 5,000 birds were recorded and subsequently correlated with the physiological state of the birds, such as the state and degree of moult and breeding condition. More than 200 lobes from these thymus glands were excised and examined by routine histological methods using impression smears, paraffin sections and araldite embedded sections prepared for light and electron microscopy. This work, carried out in collaboration with other workers, will be reported in full elsewhere and is briefly summarised here.

In *Quelea quelea*, as in other birds[1], the thymus consists of a number of lobes well separated from one another in two long chains one on each side of the neck. In embryos about to hatch each lobe was found to be small (less than 1 mm long) and white; but by the age of 10 d, 17 out of 60 individuals examined (28%) had pink, enlarged (over 4 mm long) thymi; and on becoming independent at 20-d-old 264 out of 275 (96%) had enlarged thymic lobes. At the commencement of the postjuvenile moult at about 9 weeks of age, 113 out of 140 (80%) young still had enlarged thymi and over the next 3 months, during the progress of this moult, the proportion fell to 54 out of 155 (35%). The fall apparently continued during the first prenuptial moult, though by this time it was difficult to distinguish first year from older adults.

Thus in queleas, as in most other animals[2,3], maximum thymus size is reached before the onset of sexual maturity. Thereafter the thymus is said to slowly involute with age, but this is not so in queleas where the thymus glands of adults undergo rapid cycles of enlargement and regression and there are probably several such cycles in one year.

The most remarkable changes occur in breeding adults. Queleas form highly synchronised breeding colonies, each colony lasting approximately 6 weeks (after which the adults may remain in breeding condition and move away to found other colonies[4]). As Fig. 1 shows for a colony sampled in Tanzania, the percentage of adults with enlarged thymi (there was no difference in thymus size between the sexes) was low at the start of the colony as mating and laying were under way and most individuals had regressed thymi. Then, during the incubation period, the precentage of individuals with enlarged thymi increased to a peak of 70% soon after hatching, most of the rest having thymi of intermediate size (either enlarging or regressing). Thymus activity declined markedly in the latter half of the rearing period. Similar results have been obtained from other colonies, though with less complete data. With the change from a regressed to an enlarged condition the thymic lobes also changed from white to pink or bright red, and the thymic arteries and veins became prominent.

In addition to the cycle of thymus enlargement and regression in breeding colonies enlarged thymic lobes were found in about 10% of the 919 adults collected while in prenuptial moult and in 27% of the 298 birds in postnuptial moult, though the percentages varied from year to year. When wild females were kept caged in Africa and fed food and water *ad libitum*, however only 1 out of 35 birds killed at various times during the postnuptial moult had enlarged thymi. We conclude from these results that thymus enlargement associated with moult is influenced by factors other than the moult itself.

These observations substantiate Hohn's findings[5,6] of thymus enlargement following the breeding season (and therefore during the postnuptial moult) in adult mallard ducks, American robins and house sparrows; and the observations of Ward and D'Cruz[7] and Anderson[8] in which thymus enlargement in a tropical bulbul and the pheasant respectively was associated with the postnuptial moult.

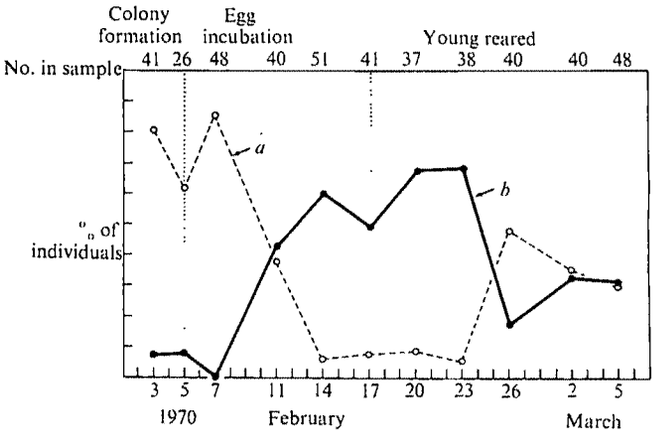

Fig. 1 Changes in the % of adult individuals with enlarged and regressed thymi in a synchronised breeding colony at Makuyuni, Tanzania. For each sample the remaining % represents birds with intermediate thymi (enlarging or regressing). The laying and hatching data are mean values for the colony. *a*, Regressed thymi; *b*, enlarged thymi.

Histologically, all except fully regressed lobes were composed of a peripheral cortex and a central medulla. The cortex of enlarging lobes contained mainly small lymphocytes (average 3–4 μm nuclear diameter) and displayed a high level of mitosis. In the enlarged lobe the typical cortical lymphocyte was in certain regions interspersed with lymphocyte-like cells[9], early erythroid cells (which were found by use of the analytical microscope EMMA-4 to contain iron), immature erythrocytes (polychromatophilic erythroblasts), mature erythrocytes or pyknotic cells. In the enlarged thymi of breeding adults the entire cortex of most lobes was packed with immature or mature erythrocytes with few, if any, thymic lymphocytes present; in some enlarged lobes the medulla also contained immature or mature erythrocytes. The presence of enormous numbers of erythrocytes imparted a bright red colour to the enlarged lobe which persisted in some lobes of intermediate size that we regarded as regressing. In regressing lobes, mitosis was not apparent, and the cortex contained very large numbers of erythrocytes which also filled all the blood vessels in the lobes. The medulla contained large Hassall's corpuscles which were not well developed in enlarging lobes. It seemed as though the efflux of erythrocytes from the enlarged lobes of breeding adults was sudden, for in some individuals collapsed lobes with little or no cortex were found.

Although invasion of the thymic lobes by immature erythrocytes produced elsewhere in the body cannot be entirely ruled out, the large numbers of these immature cells and the similarity between lymphocyte-like and early erythroid cells suggests that the erythrocytes were developing *in situ*. Terni[10] in 1924 considered the thymus of birds to be erythropoietic; and Albert, Wolf and Pryjma[11] presented evidence for erythropoiesis in the mouse thymus. Sealander and Bickerstaff[12] found a rise in red cell counts correlated with increased thymus weight in wild red-backed mice. Granulopoiesis has been demonstrated in the rat thymus[13–17] and we have found immature granulocytes (myelocytes) on electron micrographs of the *Quelea quelea* material. Pease[18] showed that the myeloblast is the primitive stem cell of the granulocytic and erythrocytic lines of cell development. Thus, erythropoiesis within the thymus is not an unprecedented concept. Identification of erythroid precursor cells is beyond the scope of this study but in view of the postulated role of the small lymphocyte in bone marrow erythropoiesis[9], the transformation of small lymphocytes under phytohaemagglutinin[9,20] and the similarity between the small lymphocytes of the marrow and thymus

in mice[21] the role of the small lymphocyte in the thymus needs investigating.

The significance of thymic erythropoiesis in the life of *Quelea quelea* is still a subject for speculation. The thymus enlarges while the young bird is growing rapidly and acquiring its first (juvenile) plumage and remains enlarged in most individuals well into the postjuvenile moult. In adults, it frequently becomes enlarged during moult and, in most if not all individuals, during the middle period of a breeding session. As an individual probably rears several broods in the course of a single breeding season, and moults both before and after the breeding season, we are left with the impression that a typical quelea may experience several complete cycles of thymus enlargement and recession each year of its adult life. There is reason to believe that the thymus enlarges whenever the need for extra erythrocytes is great, for example, during initial body growth and subsequently during each moult when large numbers of new feathers are growing and during the incubation period in a breeding colony when the adults are then recovering from a period of severe adverse nutritional balance that occurs after the start of each breeding session (ref. 22 and P.W., unpublished). Inanition (in this case manifested by a great fall in the bird's fat and protein reserves) is known to inhibit erythropoiesis[23,24], a massive production of erythrocytes following this period (that is, during the incubation period) seems quite feasible. At all these times the 14–16 lobes of the thymus may make a considerable contribution to the increased demand for red blood cells.

While the cyclic erythropoiesis that we have observed in the thymus of adult *Quelea quelea* has not previously been reported, this does not necessarily mean that it is exceptional for there has been no detailed study of the thymus of any other wild bird or mammal and for various reasons it may be expected not to occur in captive, domestic or laboratory animals.

Evidence of hydrophobic interaction in adhesion to tissue

Reaggregation and agglutination of cells *in vitro* have served extensively as model systems in the evaluation of various adhesion phenomena that occur *in vivo*. Such studies have revealed factors that influence cell aggregation[1–3], but the mechanism involved at the molecular level has not been investigated fully. In the agglutination of trypsin-treated and virus-transformed cells by concanavalin A, intercellular cross-linking of receptors by the plant lectin is believed to be necessary after ionic repulsion[4,5]. The adhesion of cells may not, however, depend exclusively on the formation of cross links[6]. Hydrophobic interaction is known to be involved in the aggregation of cell surface components[7], in the solution behaviour of proteins[8] and in adsorption[9], but its contribution to adhesion involving a biological surface has not been considered. This is chiefly because of the difficulty of demonstrating experimentally, by conventional techniques, that hydrophobic interaction can indeed contribute to any significant extent and result in adhesion. I describe here the use of a reactive polyurethane prepolymer to evaluate the conditions required for adhesion to the surface of connective tissue due to hydrophobic interaction.

Castor oil was mixed with the extremely reactive tetrafluoro-1,3-phenylene diisocyanate to produce a syrupy polyurethane prepolymer[10] which contained potentially reactive isocyanate groups[11]. When this preparation was applied to a wound on the skin of a rat (see legend to Fig. 1), further reaction was initiated by the moisture present, and the prepolymer solidified in 0.3–2.0 min. If hydrophobic interaction was adequate, adhesion should have developed after solidification of the prepolymer. Even with various combinations of castor oil and tetrafluoro-1,3-phenylene diisocyanate, however adhesion was insignificant (Fig. 1*a*), and limited to the stratum corneum region of the epidermis. When some tolylene diisocyanate was added to the prepolymer, and the mixture was allowed to polymerise on the tissue *in vivo*, the degree of adhesion changed with the amount added (Fig. 1*b*). Maximum adhesion was found with 4–6 mM tolylene diisocyanate. Adhesion could also be improved considerably by priming the tissue surface with tolylene diisocyanate. This compond could cross link the prepolymer with tissue during polymerisation. If this was the situation, the observed adhesion could not be attributed to hydrophobic interaction. *n*-Hexyl isocyanate, however, which could not form cross links as a monoisocyanate, effected the same degree of adhesion (Fig. 1*b* and *c*) when mixed with the prepolymer. Therefore, the condensation of *n*-hexyl isocyanate with receptors on the tissue surface must have made the tissue surface suitable for adhesion. This conclusion was supported by the observation that the degree of adhesion of the hydrophobic prepolymer changed with the number of carbon atoms in an *n*-alkyl isocyanate (Fig. 1*c*). Maximum adhesion resulted when there were six to eight carbon atoms in the hydrocarbon chain. This was because higher or lower homologues did not have the proper hydrophilic-to-hydrophobic balance in aqueous media[12] for the isocyanate group to react with tissue and effect maximum adhesion.

Under experimental conditions comparable with those on the tissue surface, isocyanates react only with the primary amino and the sulphydryl groups in proteins[13,14], of which there are few in connective tissue. It is remarkable that the conversion of some of the receptor sites is sufficient to alter

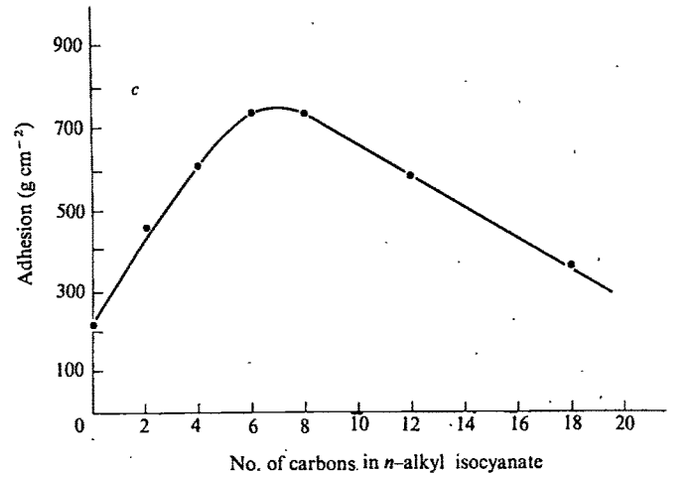

Fig. 1 Adhesion of the hydrophobic prepolymer to tissue. Several samples containing 1 mM castor oil, 4 mM tetrahydrofuran, 1 mM pyridine and a silicone surfactant[10] (0.4%, w/w) were prepared. These samples were converted into prepolymer by mixing with tetrafluoro–1,3–phenylene diisocyanate. The concentrations of tetrafluoro–1,3–phenylene, diisocyanate, tolylene diisocyanate or *n*–alkyl isocyanate required are indicated on the abscissae. Each prepolymer sample of a particular composition was used to close four 1.5 cm stab wounds on the dorsal skin of an anaesthetised Wistar rat. The adhesion of the prepolymer to tissue was assessed on a pneumatic tensiometer[10]. Each point on the graphs was the average of the four determinations on the same animal. *a*, Prepolymer samples contained various concentrations of tetrafluoro–1,3–phenylene diisocyanate only. *b*, Various concentrations of tolylene diisocyanate were added to prepolymer samples made with 4 mM tetrafluoro–1,3–phenylene diisocyanate. The horizontal part of the curve was due to cohesive failure of the solidified prepolymer. *c*, Each sample of the prepolymer was prepared with 4 mM tetrafluoro–1,3–phenylene diisocyanate, and then mixed with 4 mM *n*–alkyl isocyanate which had the required number of carbon atoms as indicated.

the surface hydrophobic character, and effect adhesion in the presence of other unreacted polar groups on tissue components.

These results show that hydrophobic interaction can result in adhesion on a biological surface. The formation of cross links and the nature of tissue surface components do not seem to be critical factors. The adhesion due to this interaction is regulated by the concentration of the converted receptor sites and their hydrophobic characteristics at the interface.

The influence of hydrophobic interaction has been observed to extend to a distance of several microns in the case of the chemotactic attraction of leukocytes by conjugated proteins[15,16]. On the surface of unassociated or dissociated cells, requirements for adhesion due to strong hydrophobic interaction, as I have established here, can be more easily achieved by diffusion[5,17] and configurational changes[15,18] of surface components. Therefore the contribution of hydrophobic interaction should be given full consideration in studies of adhesion phenomena *in vitro*[3,5,6].

I thank the National Research Council of Canada for partial support.

H_2-receptors in peripheral blood vessels

The recent observation that certain histamine responses which were resistant to antihistaminic blockade may now be abolished

by the newly synthesised compounds burimamide (N-methyl-N[1] [4-(4/5)-imidasolyl) butyl] thiourea) and metiamide (N-methyl-N[1] [2/(5 methylimidazol-4-yl) methylthio/ethyl] thiourea) (both compounds, Smith, Kline and French) has culminated in the interpretation of histamine action in terms of both H_1- and H_2-receptors[1]. Until now the attention of workers in this field has centred upon gastric acid secretion. Our own studies, however, have been directed at the receptor control of the microcirculation and we have previously reported failure of conventional antihistaminics to block histamine responses in our experimental model[2]. Here we report results obtained in the canine diarthrodial joint which demonstrate the abolition of histamine responses by H_2 and not by H_1-blocking compounds and thus supporting the conclusion that H_2-receptors are involved in the control of peripheral blood vessels.

The clearance rate of radioactive xenon (^{133}Xe) from a diarthrodial joint following intraarticular injection affords an indirect measure of synovial tissue perfusion[3,4]. Less than 0.2 ml of the gas dissolved in sterile 0.9% sodium chloride was injected into the diarthrodial joints of anaesthetised adult dogs and the clearance followed by means of a thallium-activated sodium iodide scintillation crystal positioned above the joint and connected to a photomultiplier, pulse height analyser and ratemeter recording on a Rikadenki chart recorder. From a semilogarithmic plot of the count rate the half life ($T_{\frac{1}{2}}$) (min) of the clearance rate was calculated. This technique has been used in the past to demonstrate the presence of adrenergic and cholinergic receptors in the synovial microvasculature, and although there is considerable individual variation in clearance rate, the method has provided acceptable reproducibility with repeat studies on the same joint[4].

These studies were carried out on adult dogs weighing between 22 and 32 kg using a standard anaesthetic and experimental technique.

Both agonist and antagonist drugs were injected intra-articularly and various doses of each drug (histamine 1–2.5 μg, metiamide 50–1,000 μg and mepyramine 500 and 1,000 μg were used in these studies.

The relationship between agonist and antagonist was studied in each experiment by injecting first the antagonist followed 10–20 min later by histamine.

Histamine was supplied as histamine acid phosphate (1 mg ml^{-1} (Evans Medical)), mepyramine as mepyramine maleate (50 mg ml^{-1}) (Anthisan, May and Baker) and metiamide was obtained as a powder from Smith, Kline and French Laboratories. All drug dilutions were with isotonic 0.9% sodium chloride or sterile water.

*Indicates instances of complete H_2-receptor blockade.

The results are shown in Tables 1 and 2. Histamine consistently increased the xenon clearance rate in doses of 1 μg and 2.5 μg (Table 1). This response was not abolished by mepyramine maleate in any concentration ratio. Metiamide alone produced no consistent change in xenon clearance rate (Table 2) but completely abolished the action of histamine at dose ratios of 500:1 and 1,000:1 (Met:H). Variable responses were obtained at the ratio of 200:1 and the histamine vasodilator response was clearly apparent at lower concentration ratios.

The abolition of vasodilatation induced by histamine in peripheral blood vessels by metiamide and not by

mepyramine maleate strongly indicates that the effect of histamine in this experimental model is an H_2-mediated response. Other workers have documented involvement of both H_1 and H_2-receptors in larger blood vessels[5,6]. Reed *et al.*[7] have documented H_2-receptor abolition of vasodilatation induced by histamine in gastric mucosa using the amidopyrine technique and our results using a radioactive tracer clearance technique are in accord with theirs. The implications of lipid soluble inert gas clearance rates and their relationship to tissue perfusion have previously been discussed[4]. The evidence supports the contention that large changes in clearance rates, produced pharmacologically, may be interpreted as an alteration in tissue perfusion. The expression of results in terms of absolute flow rate per tissue volume, however, is more contentious.

If, as these results indicate, histamine H_2-receptors are implicated in the control of peripheral blood vessels, a rational explanation is available for the first time for the failure of conventional antihistamine to completely reverse the effect of histamine on systemic blood pressure responses[8]. In addition, the potential interference in vascular responses mediated by histamine offered by metiamide offers an important new approach to the therapy of inflammatory joint disease. It is also conceivable that these methods may be applicable to the study of the relationship between hydrogen ion secretion and peripheral tissue perfusion in diarthrodial joints and in gastric mucosa[7] and we are currently exploring these possibilities.

We thank Dr M. Bloch and Smith, Kline and French Ltd for advice and for providing the drug metiamide and to the Wellcome Surgical Research Institute, Dr M. Harper and J. G. Littlejohn, for providing facilities and assistance. Financial assistance was provided by the Arthritis and Rheumatism Council (Great Britain).

Binding of concanavalin A and ricin to synaptic junctions of rat brain

THE synaptic junction is the intercellular contact where bioelectrical impulses are transferred and transformed by neurotransmitters. The molecular mechanism of impulse transformation is still largely unknown. To understand this process, a detailed knowledge of the structure of the synaptic apparatus is essential. The available information on the morphology and cytochemistry of synapses has recently been reviewed[1]. To arrive at a more precise morphological characterisation of the synaptic junction with respect to carbohydrate moieties[2,3], we investigated the capacity of the plant lectins concanavalin A (con A) and ricin, labelled with ferritin[4], to bind to isolated synaptosomes (that is, pinched-off axon terminals) and synaptic junctions.

A crude mitochondrial pellet obtained from the brains of adult male Sprague–Dawley rats was further fractionated according to the technique of Levitan *et al.*[5] to isolate synaptosomal membranes. This fraction was treated with the detergent Triton X–100 at a concentration of 4 mg ml^{-1} (protein[6] and Triton X–100 in a ratio of 1: 1 by weight), as described by Cotman *et al.*[7]. The resulting suspension was layered on a discontinuous sucrose gradient to isolate the synaptic junctions[7].

Concanavalin A (Calbiochem) was coupled to ferritin (Schwarz/Mann) with glutaraldehyde (Polysciences) at a molar ratio of 1.0 in the presence of 0.2 M α-methyl-glucoside in phosphate buffered saline (PBS) at *p*H 7.3-7.5 (ref. 8). Ferritin-con A and con A were isolated by affinity chromatography on Sepharose G–200 (Pharmacia) and eluted with 0.1 M α-methyl-glucoside. Ferritin-labelled con A was then separated from unreacted con A by density gradient centrifugation[9]. Ricin was similarly coupled to ferritin and purified according to the same procedure with the exception that Sepharose 4B gel (Pharmacia) and galactose were used instead of Sephadex and α-methyl-glucoside[10,11].

The crude mitochondrial and the synaptic junctional fractions were incubated in 0.2–0.5 ml ferritin-con A 1–2 mg ferritin ml^{-1} in PBS molar ratio ferritin: con A about 1: 3) or in ferritin-ricin (0.4–0.8 mg ferritin ml^{-1} in PBS, molar ratio ferritin: ricin about 1: 3) at 20° C for 1 h. As a control for the specificity of the lectin binding, samples were also incubated in the presence of 0.2 M inhibitor (α-methyl-mannoside for con A, galactose for ricin). After the incubation, the suspensions were diluted 20–50-fold with PBS, centrifuged at 10,000*g* for 15 min and washed twice with PBS. The sediments were fixed in 2.5% buffered[12] glutaraldehyde (Polysciences) for 30 min at 20° C, followed by 1% buffered[12] osmium tetroxide for 1.5 h at 4° C, dehydrated through graded acetones and embedded in Araldite. Thin sections were stained with uranyl acetate and lead citrate.

We found that of all the synaptic elements investigated the synaptic cleft had the greatest binding capacity for both ferritin-con A (Fig. 1*a, b, c*) and ferritin-ricin (Fig. 1*d*); the latter, however, bound to a lesser extent than ferritin-con A. In all control experiments, the binding of lectins was completely inhibited by the presence of the appropriate hapten inhibitor. Compared with intact synaptosomes (Fig. 1*a*), the cleft region of isolated synaptic junctions (Fig. 1*b, c*) was considerably more densely coated with labelled con A. Except in the synaptic cleft region, staining of the synaptic junction was negligible. Treatment with Triton, which removes a large part of the presynaptic membrane material from synaptosomes, seems to result in extensive exposure of binding sites located in the cleft region (Fig. 1*b, c, d,*); the penetration of ferritin-labelled con A into the synaptic cleft of intact synaptosomes is obviously restricted (Fig. 1*a*). Furthermore, the extent to which ferritin-con A binds does not depend on the presence of an intact postsynaptic membrane (Fig. 1*b, c*).

From these findings we come to the following conclusions. (1) The synaptic cleft contains a high density of con A receptors (believed to be mannosyl or glucosyl end-groups[13]) and an appreciable number of ricin receptors (believed to be galactose end-groups). (2) The consistency of the cleft material in intact synaptosomes is such as to allow the penetration of the comparatively large ferritin-con A molecules (about 150 Å in diameter[13,14]) (Fig. 1*a*). After fixation

of the synaptosomes with glutaraldehyde, the accessibility of lectin-binding sites in the synaptic cleft is abolished[15]. (3) The lectin-binding carbohydrate groups are firmly bound to the cleft region, since they are insensitive to the detergent treatment; they could be anchored within that part of the postsynaptic web which is in contact with the synaptic cleft. In such an arrangement, the connecting molecular links would run through the postsynaptic membrane. Alternatively, the removal of the postsynaptic membrane by the detergent could simply expose additional binding groups.

Fig. 1 *a*, Synaptosome labelled with ferritin-con A; ferritin-con A is dispersed over the membrane of the axon terminal (recognisable by the synaptic vesicles) and the postsynaptic membrane. Ferritin-con A can penetrate the synaptic cleft (arrow) and bind there specifically (× 27,000); *b*, Synaptic junction stained with ferritin-con A; postsynaptic membrane dissolved by Triton X-100 (× 34,200). *c*, Synaptic junction stained with ferritin-con A; postsynaptic membrane intact (× 34,200). *d*, Synaptic junction stained with ferritin-ricin; postsynaptic membrane dissolved by Triton X-100 (×34,200).

The high density of con A-receptors at the synaptic junctions was subsequently exploited for their purification on con A-Sepharose gel (Pharmacia). In preliminary experiments, a three-fold enrichment (as judged by morphometric analysis of electron micrographs) of synaptic junctions compared with the final material from conventional procedures (density gradient) was obtained.

We thank W. Schweizer and J. Heid for experimental assistance and Drs S. de Petris and G. L. Nicolson for suggestions concerning the coupling of concanavalin A to ferritin. The ricin was a gift from Professor H. J. Horstmann, University of Erlangen, Germany.

Toxins of *Vibrio cholerae* and *Escherichia coli* stimulate adenyl cyclase in rat fat cells

RAT epididymal fat cells respond to enterotoxins of *Vibrio cholerae* and *Escherichia coli* with increased membrane adenyl cyclase activity and glycerol release[1–3]. Cholera toxin increases adenyl cyclase activity in many other tissues and cells, including intestine, leukocytes, immunocytes, platelets and liver[4–6]. Here we report studies on the response of fat cells to these bacterial toxins and their effect on membrane adenyl cyclase activation by adrenaline.

E. coli toxin was prepared from a Millipore filtrate of an 18h culture of a strain of *E. coli* previously isolated from a patient with nonvibrio cholera[7,8] grown in medium containing the following concentrations of materials in g l^{-1}: 20 g Bacto-Difco casamino acids, 1.5 g Bacto-Difco yeast extract, 2.5 g NaCl, 8.71 g K_2HPO_4 (0.05 M), and 1.0 ml Trace salts solution (containing 50 g l^{-1} $MgSO_4$, 5.0 g l^{-1} $MnCl_2$, 5.0 g l^{-1} $FeCl_3$ dissolved in 0.001 N H_2SO_4). The mixture was adjusted to *p*H 8.5 with 0.1 n NaOH. Cultures were grown with shaking 500 ml in a 2.5 l low-form flask. After Millipore filtration, the TRY culture media supernatant was concentrated by UM-10 Diaflow filtration to a final concentration of 10 mg ml^{-1}. Highly purified *V. cholerae* toxin was prepared by Finkelstein, according to a method previously described[9]. Both toxins were tested for their ability to produce fluid loss in duodenal loops of mongrel dogs[10]. Fat cells were isolated from the epididymal fat pads of male Sprague-Dawley rats by treatment with collagenase (4 mg ml^{-1}) for 1 h, filtration through silk screen, and subsequent washing three times with buffer. All incubations were carried out in Krebs-Ringer phosphate buffer, *p*H 7.2, with albumin (3.63 g per 120 ml) while shaking at 60 r.p.m. in a 37°C water bath. Toxins were added at time zero at concentrations of 1 mg ml^{-1} (*E. coli*) and 1 μg ml^{-1} (*V. cholerae*) to fat cells 0.5 g 1.0 ml. At the end of 10 min, all samples were diluted with buffer to final volume of 5 ml (except the 5 min point which was diluted at 5 min). Incubation was terminated by centrifugation of cells and media for 1 min at 1,500 r.p.m. and removal of infranatant buffer for glycerol determination[11]. Fat cells were lysed by exposure to chilled (4°C) distilled water and mixing twice on a vortex shaker. Membranes were isolated in a pellet by centrifugation at 12,000*g* for 10 min at 4° C. Pellets were resuspended in cold Tris–$MgCl_2$ buffer (75 mM Tris, 25 mM $MgCl_2$, *p*H

8.0) adjusted to make a protein concentration of 25–100 μg in 55 μl of total reaction mixture. Adenyl cyclase activity was subsequently measured by conversion of ^{32}P–ATP to ^{32}P–cyclic AMP according to the method of Krishna[12]. The responsiveness of membrane adenyl cyclase to adrenaline was evaluated by adding 5.5 μM adrenaline to the adenyl cyclase assay of membranes from control cells and exposed cells exposed to toxin.

The stimulation of membrane adenyl cyclase by *E. coli* toxin was at its maximum (642 ± 269 pmol cyclic AMP per mg protein per 10 min increase over control) by 30 min, falling to control levels within 60 min (Fig. 1*a*). The response to cholera toxin, however, was not measurable until after 60 min and continued to rise to a plateau of 1244±121 pmol cyclic AMP mg^{-1} protein per 10 min increase over control adenyl cyclase activity at 3–4 h. The action of a single dose of cholera toxin on gut cells is known to continue for at least 12 h but measurement of duration is limited in our system by viability of isolated fat cells[4]. Statements about the effects after 3 h are not therefore possible.

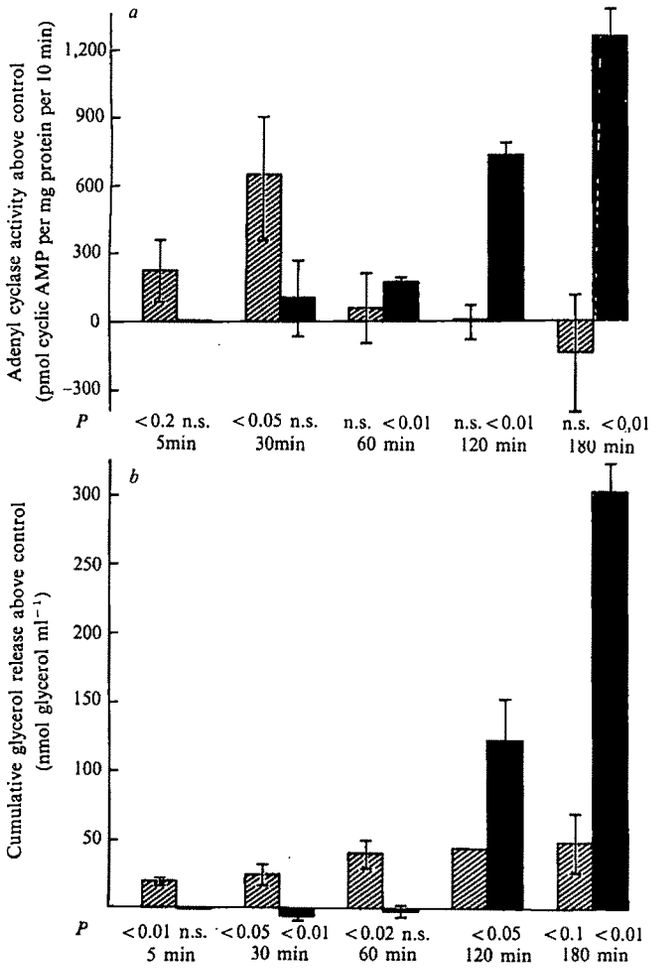

Fig. 1 Time course of the response of isolated rat epididymal fat cells to *E. coli* ▨ or *V. cholerae* (■) enterotoxins (9195 and 1071, respectively) measured by adenyl cyclase activity in pmole cyclic AMP per mg protein per 10 min above control values (*a*), or cumulative glycerol release in nmol ml^{-1} above controls (*b*). Values expressed as mean ± s.e.m.

Glycerol release in response to cholera toxin began after 60 min and continued beyond 3 h. Neither the adenyl cyclase activation nor the glycerol release induced by cholera toxin was significantly altered by the five-fold dilution of cells and toxin after the initial 10 min incubation, indicating rapid and strong binding of toxin to cell. A significant lipolytic response to *E. coli* toxin was seen at 5 min. This activity was heat labile (boiling for 10 min). By 3 h a total 48 nmol ml^{-1} of glycerol had been released. Cells which were not diluted as described previously and were exposed continuously to 1 mg ml^{-1} of *E. coli* toxin released 138 nmol ml^{-1} of glycerol by 3 h. This difference in response to the same initial concentration and total dose of toxin indicates a more transient or less avid interaction with cells. A similar action of *E. coli* toxin on canine intestine has been reported[10]. Preliminary experiments with fat cells indicate that washing cells previously exposed to toxin has no effect on response to cholera toxin, but washing cells exposed to *E. coli* toxin at 5 min can prevent a further rise in adenyl cyclase activity and glycerol release.

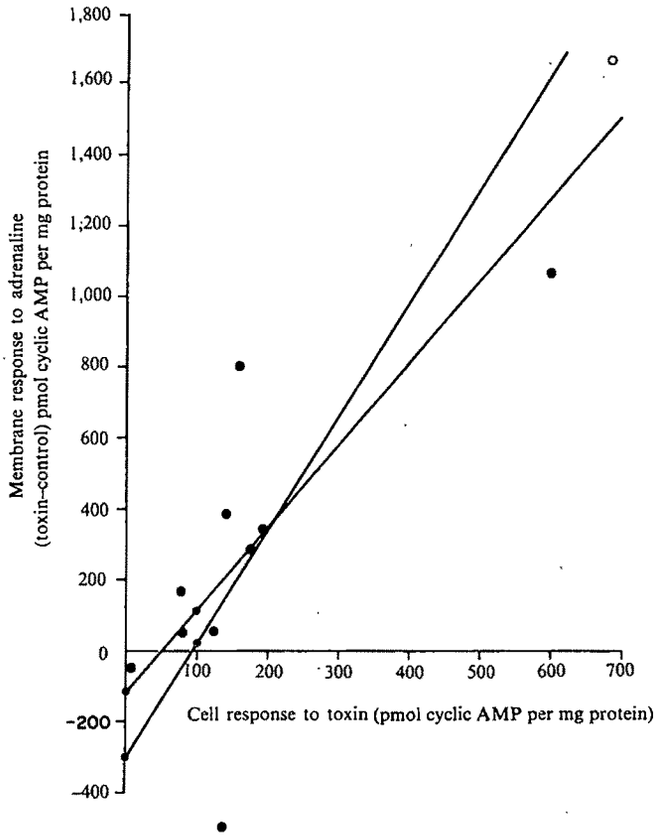

Fig. 2 Responsiveness to adrenaline of membranes of cells previously exposed to *E. coli* ($n=14$) or *V. cholerae* ($n=1$) toxins. ●, Cells exposed to E. coli toxin; ○, cells exposed to cholera toxin. $R=0.86$ $P < 0.01$. The regression lines indicate the slopes at 95% confidence limits.

In spite of the marked difference in the time course of adenyl cyclase stimulation by these two bacterial toxins, both have a significant effect on the responsiveness of membrane adenyl cyclase to further stimulation by adrenaline. Exposure of membranes to 5.5 μM adrenaline at the time of adenyl cyclase assay resulted in a significantly greater increase in adenyl cyclase activity in membranes previously exposed to either toxin than in control membranes (Fig. 2). This heightened response was greatest in membranes showing the greatest response to either toxin.

Enterotoxins of *E. coli* and *V. cholerae* produce gut fluid loss by similar actions on ion movement across gut mucosa. They each produce an altered ion flux by stimulating adenyl cyclase and thereby increasing cyclic AMP levels[10,13]. Each affects tissues other than intestinal mucosa, producing effects compatible with increased levels of cyclic AMP. There is also a close antigenic relationship between the heat-labile components of *E. coli* and enterotoxins demonstrated by immunological cross reactivity with specific antisera[14].

Although the relationship to toxin receptor and regulator to the hormonal receptor and regulator is not known, other studies have indicated that toxin action does not interfere with normal channels of hormone action[1,16]. Here, we have demonstrated not only a lack of interference, but also a marked facilitation by toxin of cellular response to a hormonal stimulus. The enhanced responsiveness of cell membrane adenyl cyclase to adrenaline is related directly to the response of cells to toxin. Thus, stimulation of whole cells by toxin sensitises their membranes to subsequent catecholamine challenge. The mechanism of this enhanced hormonal responsiveness is not clear.

V. cholerae infections are restricted to the gut lumen and the action of its enterotoxin is only on intestinal epithelium. It will be of interest to determine whether the sensitisation of intestinal epithelium to hormonal stimuli plays a role in cholera in addition to the known direct action of cholera toxin. The *E. coli* enterotoxin(s), however, may not be restricted in their action to the intestine as *E. coli* frequently causes tissue infections and septicaemia. Should enterotoxin production occur in the blood stream or other tissues, a variety of biological effects might be expected based both on the direct stimulation of adenyl cyclase in the involved tissues and on enhanced responsiveness to normal hormonal stimuli. Such effects are seen when cholera toxin is given parenterally to animals[17]. Some effects such as hypersensitivity to catecholamines have already been observed and attributed, perhaps erroneously, to endotoxin[18].

Subterminal motor nerve abnormalities in psychotic patients

THERE is considerable evidence of neuromuscular dysfunction in most patients with all types of the functional psychoses. Examples of such dysfunction are (1) increased activity of skeletal-muscle-type creatine phosphokinase (CPK) in serum in the acute stage of psychosis[1–4]; (2) abnormally large increases in serum CPK activity with a standardised exercise test performed by patients in symptomatic remission[5]; (3) morphological abnormalities in skeletal muscle fibres at biopsy, particularly scattered atrophic fibres and extensive areas of Z-band streaming[6–8]; and (4) abnormalities of eye movements in tracking a pendulum[9]. The skeletal muscle fibre abnormalities found in psychotic patients are likely to be neurogenic in origin[10].

We now report neurological abnormalities of subterminal motor axons in 21 out of 29 psychotic patients. Our subjects were 16 acute and three chronic schizophrenics, one patient with a paranoid psychosis, four manic-depressives—manic or hypomanic phase—five psychotic depressives and two nonpsychotic hospitalised depressed patients. Diagnoses were made by consensus of two psychiatrists and one social worker without knowledge of the

Fig. 1 The subterminal nerve ends in five branches. The two branches on the right end on the same skeletal muscle fibre. The stain was methylene blue, ×360.

biological data. All patients with the diagnosis of schizophrenia satisfied the criteria of the New Haven Schizophrenia Index[11]. The patient groups consisted of 15 males and 14 females; their median age was 24 (range, 17–45). The control group consisted of three male and three female volunteers who were accepted only after a thorough history revealed no personal or familial medical illness that might affect neuromuscular pathology. Their median age was 23 (range, 22–35).

The peroneus brevis was biopsied under local anaesthesia. The subterminal motor nerves were stained supravitally with methylene blue[12] and the absolute and functional terminal innervation ratios (ATIR and FTIR respectively)[13] were determined by carefully following at least 100 sub-

terminal motor nerves selected randomly from all of the slides prepared from each patient. All histological work was performed on a blind basis by coding the slides. To test the reliability of the method, investigators made independent assessments of coded slides. The inter-rater correlation coefficient of six innervation ratios was $r=0.932$ ($P<0.01$). We have also computed the percentage of axons with more than two branches, since such extensive branching has been considered to be diagnostic of denervation and reinnervation. Two other small samples from the same muscle were obtained for histochemical studies and phase microscopy by methods described previously[6,7].

TIRs for patients and controls are summarised in Table 1.

Table 1 Absolute and functional terminal innervation ratios

Group	N	Absolute TIR Mean s.d.	Range	Functional TIR Mean s.d.	Range
Chicago controls	6	1.08±0.049	1.05–1.16	1.07±0.052	1.05–1.16
Controls of Cöers[8,12]	56	—	—	1.11±0.05	1.01–1.20
All psychotics	29	1.49±0.46‡	1.00–2.90	1.39±0.34†§	1.00–2.35
All schizophrenics	19	1.46±0.50†	1.00–2.90	1.36±0.36†§	1.00–2.35
Affective psychoses	9	1.57±0.34†	1.04–1.93	1.48±0.31†§	1.03–1.87
Neurotic depression	2	1.11±0.01*	1.10–1.12	1.11±0.01*	1.09–1.12

The ATIR is defined as the number of end plates innervated by a given number of axons divided by that number of axons. Similarly, the FTIR is defined as the number of muscle fibres innervated by a given number of axons divided by that number of axons. The mean ATIR and FTIR of the experimental groups were compared with those of the Chicago controls by means of a Mann-Whitney U test, two-tailed: * $P > 0.5$; † $P > 0.01$; ‡ $P > 0.005$.

The mean FTIR of the experimental subjects were compared with those of the controls of Cöers and colleagues[14] using a two-tailed t-test: § $P < 0.001$; ¶ $P > 0.5$.

The TIRs of the six controls were in excellent agreement with those reported by Cöers *et al.*[13–15]. The 95% upper limit of normal for the ATIR was 1.16; for the FTIR it was 1.15. The TIRs of the two nonpsychotic patients were normal. Of the 29 psychotic patients, 21 had an ATIR greater than 1.16 and 19 had an FTIR greater than 1.15. The mean TIRs for all psychotic patients, and for the subgroups consisting of all schizophrenics (acute and chronic combined) and the affective psychoses (manic-depression, manic phase and psychotic depression), were significantly greater than those of our six controls and the 56 controls of Cöers *et al.*[15]. Although groups were small, comparisons of group means gave no evidence that acute compared with chronic status or paranoid compared with nonparanoid status had any relationship to the degree of abnormality of the TIRs. There also were no significant relationships between the TIRs and age, sex or race.

The mean TIRs of the 12 psychotic patients who had received the largest total of phenothiazines (8–270 g) were not significantly greater than those of the 12 patients who had received the smallest doses (0–5.8 g). Increased ratios were found in four of six psychotic patients who had received a total of less than 1 g of chlorpromazine.

The type of branching of the subterminal motor axons in the muscle of the psychotic patients is illustrated in Figs 1 and 2. The 95% confidence limit for the percentage of fibres with three or more branches was 6.2% in the six controls. Cöers *et al.* found a mean of 0.65% of subterminal axons with three or more branches in the palmaris longus and tibialis anterior muscles of 13 controls[16]. Fifteen of the twenty-nine psychotic patients had more than 6.2% of axons with three or more branches (range, 6.6–25.4%) with four patients having 20% or more of their axons with three or more branches.

The relationship between the TIRs and the results of the histochemical and phase microscopy studies of muscle fibres in the psychotic patients will be described in detail elsewhere[17]. Here we wish to indicate some important relationships between muscle fibre abnormalities and subterminal motor nerve changes. Three of the psychotic patients with an excessive percentage of fibres with three or more branches had several groups of 50–100 fibres of the same fibre type rather than the usual checkerboard pattern, or atrophic fasicles (Fig. 3). Previous studies have demonstrated a relationship between elevated FTIRs and type grouping[18]. The correlation between the FTIR and the number of small angular fibres in the sample taken for histochemistry was highly significant ($r=0.719$, $N=29$, $P<0.01$). On the other hand, there was no correlation between either TIR and the percentage of fibres with extensive areas of Z-band streaming. The TIRs of the 22 psychotic patients with abnormalities in muscle fibre morphology were, however, significantly greater than those of the seven psychotic patients without such abnormalities ($P<0.05$, two-tailed). Since scattered small angular fibres and Z-band streaming have both been described in neuropathic motor disorders[19–21], it seems likely that neuronal dysfunction is the basis for both the muscle pathology and the increased subterminal axonal branching in psychotic patients. Additional support for this hypothesis comes from the observation that the ATIR and FTIR were not significantly different in the psychotic patients. This pattern strongly suggests a neurogenic motor disorder, because in primary muscle disease the FTIR remains near unity, while the ATIR increases[13].

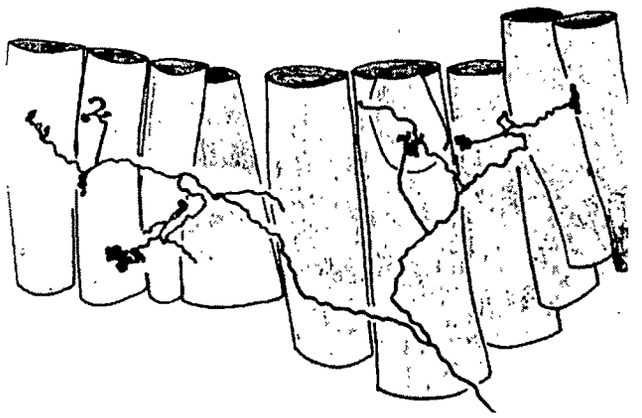

Fig. 2 Camera lucida drawing. The motor nerve can be followed to at least eight recognisable end plates. Several sprouts (branches without end plates) are evident.

In addition to the branches with terminal arborisations, excessive formation of sprouts, or immature branches, was found in 11 of 29 psychotic patients (Fig. 2). Cöers and Woolf have found that sprouting is characteristic of anterior horn cell disease and vitamin B_{12} deficiency whereas in peripheral neuritis there is little sprouting because the healthy motor neurone somata support the formation of healthy branches rather than sprouts[13]. The presence of sprouting along with fibre type grouping and excessive numbers of small angular fibres, indicates the α-motor neurone as a probable locus of neuropathology in these patients. It sems likely that the effectiveness of branching is one reason why relatively few scattered atrophic fibres are present in the psychotic patient.

These studies therefore show that there are neuropathological changes in patients with the so-called functional psychoses. The significance, if any, of these abnormalities of the motor nerves for motor performance in psychotic patients is an intriguing question. Evidence for impaired psychomotor performance in schizophrenics has been re-

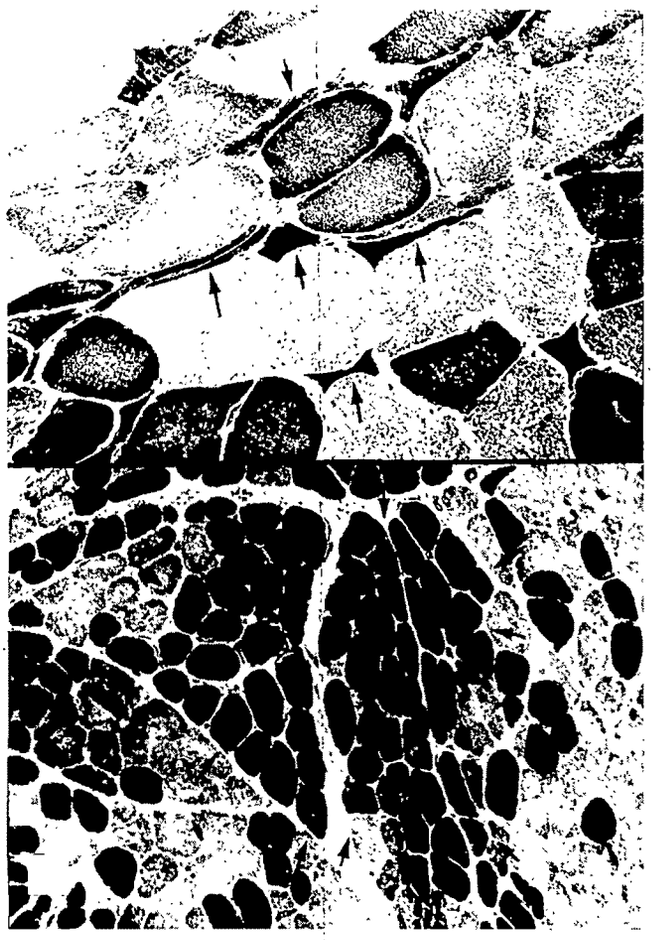

Fig. 3 Top, four small, angular atrophic type I muscle fibres are indicated by arrows. (Nicotinamide adenine dinucleotide-tetrazolium reductase, ×167.40.) Bottom, two groups of type I fibres are indicated by arrows. (Nicotinamide adenine dinucleotide-terazolium reductase, ×86.80.)

viewed recently[22]. It is conceivable that the abnormalities of motor nerves reported here might affect a number of critical fine motor processes such as eye movements, larynx and finger dexterity such that they contributed to the schizophrenics' difficulties in adaptation.

Effects of bicuculline on functions of inhibition in visual cortex

Further to a recent report[1] on the effects of intravenous bicuculline on neurones in the cat visual cortex, we feel that we should present some preliminary results from our own experiments.

In the mammalian cerebral cortex, bicuculline acts as a reversible inhibitor of the action of γ-aminobutyric acid (GABA) (ref. 2), the principal putative inhibitory neurotransmitter[3]. In the visual cortex, intracortical inhibitory interneurones may act to increase the precision with which a neurone is selectively responsive to a particular visual stimulus, for example, one specific orientation of a moving edge or bar[4,5]. The direct excitatory input to the cell from the lateral geniculate nucleus, (LGN), may only broadly 'tune' the cell in its responses to orientation, while an inhibitory input (even more broadly tuned for orientation), through intracortical interneurones, could suppress the responses to stimuli away from the optimal orientation[6–9] (Fig. 1*a*). This would give improved specificity for one particular orientation at the expense of general decreased responsiveness. According to this theory, then, blockage of intracortical inhibitory neurotransmission, such as with bicuculline, should induce an increase in the breadth of orientation tuning; a proportionately greater increase in responsiveness (Fig. 1*a*); and, perhaps, a rise in spontaneous discharge if there is tonic activity of inhibitory interneurones[10]. Also, bicuculline might reduce the specificity for stimulus length (hypercomplex cells)[11], direction and velocity of movement[8,10], and binocular suppressive interactions[12], all of which could depend on intracortical inhibitory interactions.

Pettigrew and Daniels have reported[1] that bicuculline administered intravenously increased the breadth of orientation tuning, responsiveness, and spontaneous activity of complex cells, modified the receptive fields, and sometimes abolished direction selectivity. Hypercomplex cells lost their preference for short bars. Simple cells, however, became less responsive and sometimes more narrowly tuned. Thus, their reported results partially support and partially conflict with the theory described here.

In our experiments, adult cats were paralysed with Flaxedil and artificially ventilated with N_2O/O_2 mixture[13]. Extracellular recordings were made in area 17 (verified by later histology) using glass-insulated tungsten microelectrodes and conventional amplification and display techniques. Quantitative estimations of the characteristics of each cell were made by

averaging the number of spikes given in response to several sweeps of a bright bar of optimum dimensions across the face of an oscilloscope, at many different orientations. Linear regression lines were fitted to these data to form tuning curves[14] (Fig. 1*b* and *c*). Changes in these curves after drug application were assessed, using empirical criteria for their reliability: changes in breadth of tuning of >15% and in peak response (at the optimal orientation) of >20% were considered significant[14], while *t* tests were used to assess shifts in spontaneous firing level (Table 1). Several hours were allowed between experiments on cells in the same cat to ensure complete recovery from the drug. The mechanical stability of the preparation for topical application is erratic in some experiments and has meant that few cells have been fully analysed so far.

First, the effects of intravenous bicuculline (0.2 mg kg^{-1}; K & K Laboratories) were studied on two simple and three complex cells, with essentially negative results. For perhaps a minute after injection, the EEG showed very large slow waves or epileptiform spikes (effects were inconsistent). Data were collected within 13–29 min after injection, and from these an orientation tuning curve was constructed and compared with that obtained before drug application.

No systematic changes were seen (Table 1). Intravenous application of bicuculline has unknown potential actions on neural systems (such as the retina[15], LGN (ref. 16) and reticular system[17]), and can cause tachycardia and hypertension[18]. Some of the findings of Pettigrew and Daniels[1], especially the consistently decreased responses of simple cells, cannot be easily explained in terms of neural effects within the primary visual cortex alone.

For topical application experiments, the electrode was introduced through a closed perspex chamber cemented over a 3–5 mm diameter craniotomy above the visual cortex. The chamber was filled with warmed saline through long thin tubing to damp down pulsations and the pressure was maintained at 10–20 mm H_2O. The saline could be replaced with 10^{-4}M or 10^{-5}M bicuculline as hydrochloride in saline.

Topical bicuculline broadened the tuning of all three simple cells tested (though one by only 12%) and the other predictions of the theory described above were verified completely in two of these cells (Table 1 and Fig. 1*b*). In two simple cells the receptive fields were plotted again and they had increased three-fold and five-fold in area. The possible correlation of this with alterations in responsiveness remains a matter for future investigation. One simple cell, which was clearly direction selective before application, showed reduced direction selectivity afterwards.

Of the complex cells tested, the first three gave straightforward results (Table 1). Two showed increases in breadth of tuning. One of these two fulfilled all predictions of the theory under test and also showed a quantitative reduction of direction selectivity; bars moving in the nonpreferred direction caused a 25% inhibition of spontaneous activity before drug application; but with bicuculline they caused a clear response, 24% of that in the preferred direction ($P < 0.001$). This cell was still present 3–3.5 h after drug removal, when its responses had returned to the condition before drug administration. The third complex cell showed no consistent effect of the drug. The fourth complex cell was unusual in having clear inhibitory 'side-flanks' in its orientation tuning curve before application of the drug. Topical bicuculline abolished these side flanks as well as increasing the breadth of tuning and the peak response (Fig. 1*c*).

The next day, a fifth complex cell was found in the same location in the cortex, with very similar receptive fields and tuning curve to the fourth complex cell. Immediately after the application of bicuculline there was actually a decrease in both peak response and breadth of tuning (Table 1), but after 45 min exposure, both parameters had increased above the level before the drug was given. But after more than 2 h under the influence of bicuculline (and even with an additional intravenous application; 0.4 mg kg^{-1}) statistically significant inhibitory side flanks to the tuning curve clearly persisted, with strong inhibition even for a stimulus perpendicular to the best orientation. This indicates the presence of some non-orientation-specific inhibition[19], possibly not GABA mediated[20], which may operate in addition to the orientation-specific inhibition[8,9] in some or all cells.

One cell was classified as pure direction selective, responding to movement of any stimulus in the optimal direction[21]. Its breadth of tuning for orientation increased by about 50%, and so did its peak response. This was, in fact, the only cell found showing an almost exact 'iceberg' effect, with constant slopes to the tuning curve before and after the drug, perhaps because of the removal of nonorientation-specific inhibition.

One hypercomplex cell has also been tested (in cortical layer VI : 10^{-4}M bicuculline). Before the application of bicuculline, a long bar (16°) caused slight inhibition of

Table 1 Actions of bicuculline on orientation tuning curves

Method of application	Cell type	Cortical layer	Change in breadth of tuning (%)	Change in peak response (%)	Ratio of changes (peak: breadth)	Change in spontaneous activity	Notes
Intravenous 0.2 mg kg^{-1}	Simple		(−15)	(+10)		(+)	
			(− 5)	(−17)		+	
	Complex	IV	(+ 3)	−31		−	
		VI	+22	−27		(−)	
		VI	(− 1)	+40		+	
Topical 10^{-4} or 10^{-5}M	Simple	V	(+12)	+31	2.6	(+)	*
		III	+31	+151	4.9	+	† (Fig. 1*b*)
		II	+36	(−18)		(+)	†‡
	Complex	VI	+75	+23	0.3	(+)	*
		V	+20	+88	4.4	(−)	‡
		III	(− 3)	−36		+	
		VI	+26	+100	3.8	(−)	(Fig. 1*c*)
		VI	−17	−40		−	
	Pure direction selective	V	+49	+51	1.0	(+)	†

Data were collected starting 1–5 min and finishing 13–29 min after intravenous injection, and 5–20 min to 35–60 min after topical application. All cells studied topically were within 1.6 mm of the surface. (One complex cell was studied which was 4 mm deep, beyond the probable range of drug diffusion; no effect of bicuculline was seen, and the cell has been excluded from these results.) From tuning curves like those in Fig. 1*b* and *c* the breadth of tuning (average half width[14]) and the peak response (evoked impulses at the optimal orientation) were measured before and during the application. Changes in these parameters are expressed as % increases or decreases. Values in parentheses failed to meet the criteria of significance (> 15% for breadth of tuning, >20% for peak response) established from control measurements of the inherent variability of these parameters without the application of the drug[14]. To test the prediction that the peak response should show a greater % increase than the breadth of tuning, the ratio of the two is shown for cells showing a positive change in both: ratios greater than 1.0 support the hypothesis. Changes in spontaneous activity are shown simply as an increase or a decrease (+ or −), those in parentheses being nonsignificant ($P > 0.01$). Not all cells were tested for changes in field size. Both cells examined for reduced direction selectivity (one simple, one complex) showed the effect.

* 10^{-5}M bicuculline (all others 10^{-4}M).
† Receptive field size increased.
‡ Direction selectivity reduced.

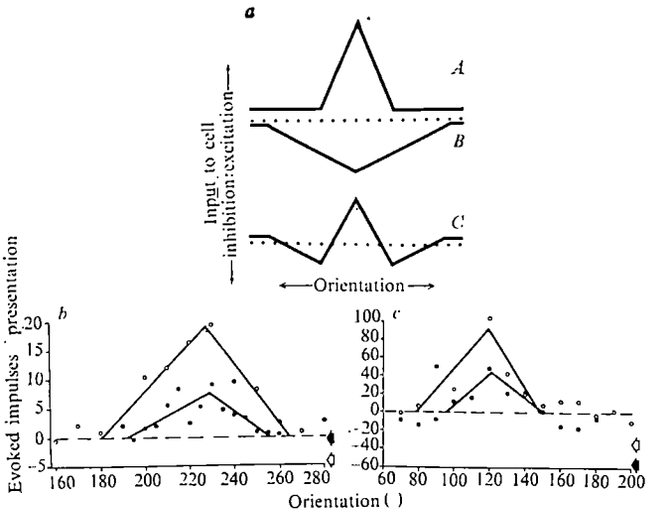

Fig. 1 *a* Diagrammatic illustration of the theory described in the text, whereby a broadly tuned excitatory input, *A*, and a more broadly tuned inhibitory input, *B*, summate (perhaps linearly, as shown here) to give the final orientational tuning curve *C*. Bicuculline should convert the cell's tuning curve from type *C* to type *A*. Normally, in cortical cells, spontaneous discharge is too low for inhibitory 'side flanks' to be seen clearly (the dotted lines represent zero firing level for the cell). Alternatively, inhibitory effects might be nonlinear, perhaps presynaptic, affecting the gain of the excitatory mechanisms[7]. *b*, Effects of bicuculline on a simple cell, D20R4 (10^{-4}M bicuculline, 15–64 min after application). *c*, Effects of bicuculline on a complex cell, D18L6 (10^{-4}M, 5–50 min after application). ●, Responses before application; ○, responses after application. The spontaneous activity was counted over the same gating period used to measure the responses. For clarity, the responses are displayed on the ordinate as the extra impulses generated by the stimulus relative to these spontaneous levels. Inhibition appears as negative values, that is reductions of the spontaneous discharge. Zero firing levels before (◀) and after (◁) the administration of the drug are shown.

spontaneous activity, but with bicuculline, a long bar produced a clear response, 24% ($P < 0.05$) of that elicited by a short bar (1.5°). Two and a half to three hours after removal of the drug, long bars again inhibited the cell slightly.

There are numerous difficulties in interpreting these results quantitatively: one is the general problem of assessing the significance of experimental changes in the characteristics of neurons that exhibit inherent variability in responsiveness[10,14,22] and a second is the uncertain nature of diffusional barriers, including distance, when a drug is applied topically. Finally, bicuculline itself occasionally has only weak or even anomalous actions as a GABA antagonist[23,24]. In spite of these problems, however, all but one of the neurones in this sample showed some if not all of the predicted effects of bicuculline. These results, together with Sillito's very recent report of the actions of iontophoretically-applied bicuculline[24], warrant further investigations into the functions of GABA in the visual cortex.

We thank E. A. Tobin for her collaboration during a visit to Cambridge in 1971. Drs J. S. Kelly and J. G. Robson gave useful discussion and R. D. Loewenbein and J. S. Dormer gave technical assistance. D.R. is an MRC scholar; equipment was provided by the H. E. Durham Fund and an MRC grant to C.B.

Constitutivity of the HCG-receptor protein in the testis of rat and man

IN a series of embryological experiments on rabbits and rats, Jost *et al.*[1] have shown that the manifestation of the male or female phenotype is strictly dependent on the presence or absence, respectively, of testosterone. The Müllerian inhibitor formed by the seminiferous tubules[2] only seems to be responsible for the retrogression of the Müllerian ducts. Thus, testosterone synthesised in foetal testes[3] is the chief organiser of masculine differentiation; a female phenotype results from the absence of testosterone. Accordingly, Ohno[4] defined maleness as the induced and femaleness as the noninuced state of genital differentation. The androgenic effects on the development of the genital structures occur during successive critical phases. For instance, the stabilisation of the Wolffian ducts in the rat occurs between days 17 and 18 (ref. 1) while the prostate is imposed on day 21 of foetal life. The imprinting of the rat hypothalamus into the male direction, responsible for the masculine secretory pattern of pituitary gonadotrophins and behaviour pattern, is established during the first two days of postnatal life[5]. Castration, hypophysectomy or injections of cyproterone acetate (a highly potent antiandrogen) before these critical stages prevent the differentiation processes but by later treatment the development is no longer affected. Similar developmental patterns may be applicable to man except for hypothalamus differentiation which is fixed as early as in the fifth month of intrauterine life[6]. Full maturity of the genital structures and particularly the onset of sperm production, are both dependent on testicular androgens, so occur rather late during the postnatal life of all mammalian species.

Testicular androgens are synthesised by stimulus of the gonadotrophic hormones, luteinising hormone (LH) or human chorionic gonadotrophin (HCG). Recent studies have shown that the gonadotrophic effect is mediated by a

Table 1 Uptake of ^{125}I-HCG by rat testicular tissue taken from pre and postnatal rats. The spleens of the prenatal animals were used as controls.

	c.p.m. bound without unlabelled HCG	c.p.m. bound plus unlabelled HCG (30 μg)	Specific uptake of ^{125}I-HCG (g × 10^{-10}) per 30 min per mg protein

Binding studies, purification and iodination of HCG were performed as described earlier[9]. All assays were performed in triplicate. The amount of specifically bound HCG was determined as the difference between the c.p.m. bound in samples with ^{125}I-HCG alone and in samples containing an excess of unlabelled HCG.

† See ref. 9.

specific HCG-receptor in the testicular Leydig cells; the stimulation of testosterone synthesis by HCG in Leydig cells is preceded by the binding of the polypeptide hormone to its specific receptor[7]. The presence of the specific HCG receptor in the developing Leydig cell should therefore be a prerequisite for testosterone synthesis and also male organogenesis in the foetus. As testosterone synthesis is required during both pre and postnatal development, it might be assumed that the HCG receptor is present throughout these periods, appearing with the first formation of Leydig cells in the primordial testis. These cells are first seen in the rat on day 14 (ref. 1) and in man around the 60th day of foetal life[8]. Here we report experiments to test this hypothesis by measuring specific binding of ^{125}I–HCG by foetal and newborn rats and human testicular tissue.

The procedure used was similar to that described earlier[9]. For the study of prenatal animals at a definite developmental stage, mating was determined by examining the presence of copulation plugs in the female rats. On the 20th day of pregnancy the animals were killed and the foetal testes removed. The testes of between 60 and 70 animals were taken together and homogenised in cold Tris-HCl buffer (0.1 M, *p*H 7.4) containing $MgCl_2$ (0.005 M) and sucrose (0.1 M); when 5-d-old rats were used, the testes of 15 animals were pooled in each assay. In the 10, 46 and 75-yr-old humans individual tests were removed 3–5 h after accidental death; the neonate died from pneumonia. Portions (1 ml) of the homogenate were incubated with 7 ng ^{125}I-HCG alone (about 5×10^4 c.p.m.), or with the addition of 30μg unlabelled HCG respectively at 32° C for 30 min (Table 1). After incubation unbound radioactivity was separated by centrifugation.

The results clearly demonstrate the presence of a specific HCG receptor in the pre and postnatal testis of the rat and man (Tables 1 and 2). In contrast to the rat, specific HCG-binding by testicular tissue in man does not vary much with age; only the 10-yr-old boy showed a relative high binding capacity. It is not yet known whether there is any correlation between high binding capacity and the onset of puberty. In rats the fluctuation in binding might be due to the varying amount of Leydig cells present during the respective developmental stages[10]. There is evidence[11] that the pattern of change in Leydig cell numbers may be similar in rat and human testicular development. Further studies are in progress to discover any correlations between hormone binding and human testicular developmental stages.

The important point is, however, that the binding capacity for HCG of the Leydig cell at each developmental stage in rat and man is sufficient to evoke a maximum response; Catt and Dufau[7] have shown that less than 1% of the HCG-receptor sites must be occupied for maximum testosterone synthesis. We conclude from our results that one of the first events occurring in the differentiating Leydig cell is the 'switching on' of the receptor synthesis so that the Leydig cells can start testosterone synthesis. The receptors become functional to guarantee that androgenic hormone synthesis is sufficient for the stepwise maturation of the androgen-dependent genital structures. Defects in the gonadotrophin receptor may result not only in infertility of the adult male but also in defects in the differentiation of male primary and secondary sexual organs. Such defects may only be apparent in the homozygous state, heterozygosity may not reveal deviations, as only a very small quantity of HCG receptors must be occupied to evoke biological response of the Leydig cells.

Table 2 Uptake of ^{125}I-HCG by human testicular tissue at different developmental stages.

	26th foetal week	Neonate (day 4)	10 yr	46 yr	75 yr
Specific uptake of ^{125}I-HCG (g × 10^{-10}) per 30 min per mg protein.	0.451 ± 0.05	0.208 ± 0.017	1.800 ± 0.12	0.293 ± 0.03	0.217 ± 0.019

For experimental procedure see text and legend of Table 1.

Constitutivity has already been supposed for the androgen receptor in the rat ventral prostate[12] and for the oestrogen receptor in the rat uterus[13]. To our knowledge, the results presented here represent the first example of constitutivity of a hormone receptor protein in mammals.

Fibril structure of collagen in egg capsule of dogfish

In spite of a wealth of information relating to the composition and structure of mesenchymal collagens, relatively little is known about the so-called 'secreted' collagens of epithelial origin which are much more limited in distribution. The materials of the selachian egg capsule has been classified as such a collagen though this claim is based on a poorly oriented high angle X-ray diffraction pattern obtained from skate egg capsules[1] and on the colorimetric detection of hydroxyproline in hydrolysates of the same material[2]. Partial amino acid analysis of this material[2] indicated a composition markedly different from pure collagens. To date there has been no report of fibrous periodicity in selachian egg capsules.

Here, we provide evidence that the inner layers of the egg capsule wall of the selachian, *Scyliorhinus caniculus* are built up from fibrils which contain a collagen-like protein, probably in association with other protein(s). The unique and highly ordered structure of these fibrils is described.

Fresh egg capsules were obtained from the Scottish Marine Biological Association Laboratories. Electron microscopical examination of ultrathin sections of the egg capsule wall fixed in glutaraldehyde and osmium tetroxide and embedded in Epon showed that the inner layers of the capsule wall consist of laminae (approximately 0.4 μm thick)

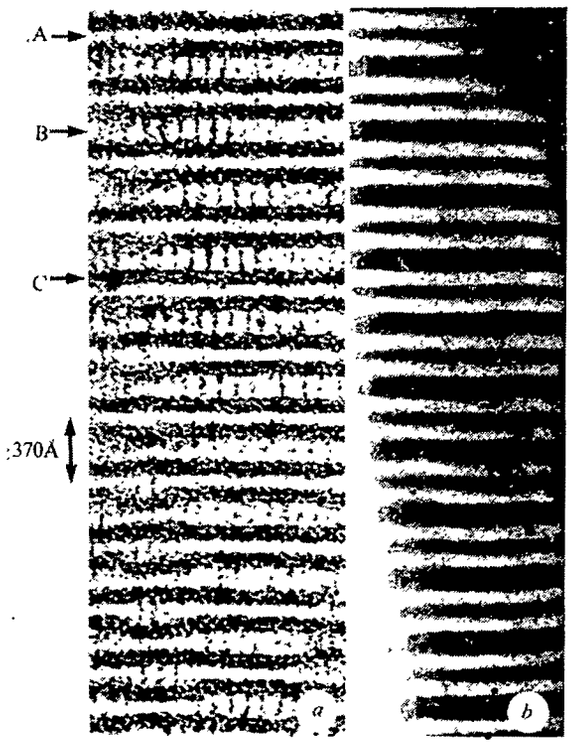

Fig. 1*a*, Axial banding pattern. Positively stained ultrathin sections. *b*, Negatively stained dispersed fibrils.

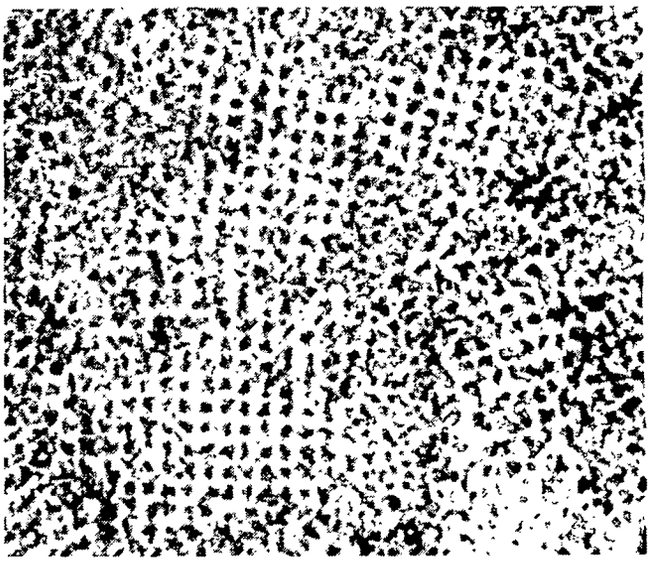

Fig. 2 Transverse section showing the intrafibrillar lattice (stained with uranyl acetate and lead citrate (X 335,000)).

which seem to be built up entirely from closely packed fibrils. In a single lamina, the long axes of the fibrils are parallel. Laminae appear stacked upon each other to give a cross ply construction such that there is an angle of approximately 45° between the long axes of the fibrils in adjacent laminae. The outermost layer of the capsule shows a different construction and is less transparent and more pigmented than the inner layers. In ultrathin sections it seems to consist of closely-packed elliptical granules (0.2–0.5 μm in diameter). Small quantities of fibrils similar to those of the inner layers are found in the interstices between the granules. Amino acid analyses of the outermost and the inner layers (Table 1) were obtained using a Locarte analyser. The outermost layer differed from the inner layers and showed a high tyrosine content (18 residues/100 residues).

The inner layers showed an amino acid composition clearly different from pure mammalian collagen (Table 1). Hot trichloracetic acid[3], however, extracted protein with a composition showing a resemblance to pure mammalian collagen and an even closer resemblance to the 'secreted' collagen of the byssus threads of *Mytilis edulis* (Table 1).

A moderately well oriented high angle X-ray diffraction pattern was obtained after slowly stretching the marginal band of the capsule to an extension of 50–70%. This pattern had the following features in common with collagen[5]: a strong meridional arc at 2.9 Å, and a weaker one at 4 Å. A broad diffuse equatorial arc at 4.5 Å, a faint diffuse equatorial spot at 6 Å and a strong one at 12 Å which on wetting became a streak with a maximum intensity at about 15 Å. Strips of the inner layers showed a sharp thermal transition (mean half shortening temperature 78° C), shrinking by about 30–40% of their resting length.

Taken together, this evidence indicates that the fibrils which comprise the inner layer of the capsule contain a protein with the configuration of a collagen together with other protein(s) not in this configuration. In this respect the fibrils appear to resemble those of elastoidin[6].

Fibrils of the inner layers of the capsule seen in ultrathin sections stained with uranyl acetate and lead citrate have a mean diameter of 1,300 Å and show an axial, centrosymmetrical banding pattern with a mean repeat period of 370 Å (Fig. 1*a*). This banding pattern is built up from alternating narrow bands (A; 70 Å wide) and broad bands (B; 120 Å wide), both of low density, separated by bands (C; 90 Å wide) of high density. The C bands can be resolved into two dense sub-bands. Fibrils dispersed from the inner layers by homogenisation and sonication show, on negative staining

with PTA or ammonium molybdate at *p*H 6.4, a banding pattern closely similar to that seen in positively stained ultrathin sections but in reversed contrast (Fig. 1*b*).

Two observations indicate that the transverse arrangement of molecules within the B bands is highly ordered. First, where the fibrils are sectioned transversely, a highly ordered array of dense dots is seen (Fig. 2). These lie in a nearly square, rhombic lattice (lattice angle 93.5°; mean length of equilaterals 80 Å). Second, in longitudinal sections where a fibril is appropriately orientated about its long axis, a pattern of evenly spaced longitudinal filamentous densities is seen traversing the B band (Fig. 1*a*). These show spacings of either approximately 80 Å or approximately 60 Å and

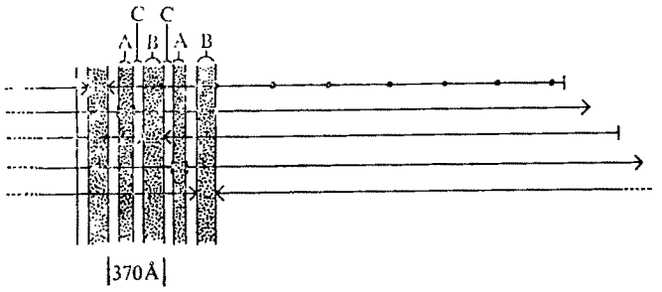

Fig. 3 Diagram illustrating the proposed longitudinal arrangement of molecules in the fibrils. Negative stain is thought to penetrate the gaps between the head ends and the tail ends. Arrowheads and bars indicate only the opposite ends of the molecule and do not imply which is the amino end.

may correspond respectively to images of the rhombic lattice viewed in the plane of the equilaterals or in the plane of the diagonals.

Although we have been unable to devise a model to account for all the features in our micrographs, the centrosymmetrical nature of the axial banding pattern and the alternation of narrow and broad bands into which negative stain can penetrate indicate that fibrous molecules are arranged longitudinally in a head-to-head, tail-to-tail fashion with gaps between the head ends of different size to the gaps between the tail ends (Fig. 3).

Although we have, so far, been unable to determine the molecular length of the collagen in this system, if it were close to that of a mammalian collagen (2,990 Å, ref. 7), the molecules would need to be staggered by about $\frac{1}{8}$ of the molecular length to produce the repeat of 370 Å (Fig. 3). Eight collagen molecules staggered in this way and packed together transversely in some form of nearly square array could account for the axial periodicity and could provide the building unit for the nearly square lattice seen in transverse sections of the fibrils.

The collagen-containing fibrils of the inner layers of the dogfish egg capsule show a unique fine structure indicating a highly ordered longitudinal and transverse arrangement of molecules. Our demonstration by electron microscopy of a nearly square unit cell (sides 80 Å) in transverse sections of these fibrils is particularly interesting in the light of the evidence from low angle X-ray diffraction for a similar lattice (sides 77 Å) (ref. 8) in the collagen fibrils of rat tail tendon.

Release of cyclic AMP from rat superior cervical ganglia after stimulation of synthesis *in vitro*

THE formation of adenosine 3′,5′-monophosphate (cyclic AMP) from adenosine 5′-triphosphate (ATP) in central nervous tissues seems to be controlled by catecholaminergic and histaminergic mechanisms[1]. Also in a peripheral autonomic ganglion, the intact superior cervical ganglion (SCG), accumulation of cyclic AMP was observed in response to electric stimulation[2] and to β-adrenergic agents[3], and histamine[4,5].

Cyclic AMP is excreted in large amounts in the urine[6], and

marked changes in the excretion rate correlate with mood changes in manic depressed patients and with response to central active drugs[7-9]. It has therefore been suspected and is supported by indirect evidence[8] that the central nervous system may be one important source of cyclic AMP in body fluids.

We have reported experimental data showing a relationship between the rate of accumulation of cyclic AMP in the cerebrospinal fluid and the amount of catecholamine synthesis in the brain[10]. These findings prompted us to study more directly the release of cyclic AMP from nervous tissues when the synthesis of the nucleotide was stimulated by biogenic amines *in vitro*.

Male Sprague Dawley rats, weighing 200 to 300 g, were killed by cervical dislocation. The superior cervical ganglia (SCG) were rapidly removed, desheathed, and kept on ice until used for incubations. The ganglia were incubated in groups of two to four in 1 ml of Krebs-Henseleit solution *p*H 7.4 containing 200 mg ml^{-1} of ascorbic acid at 37° C under an atmosphere of 95% O_2 and 5% CO_2 with or without the drugs added. Blocking agents were tested by a preincubation period of 20 min. At the end of the experiments the ganglia were homogenised and chromatographed on anion exchange columns as described[3]. Total cyclic AMP was measured in column eluates of ganglia and in incubation media according to Gilman[11]. The formation of ^{14}C-cyclic AMP was measured after preincubation of the ganglia with ^{14}C-adenine for 1 h as described for brain slices[12]. Labelled cyclic AMP was determined by thin layer chromatography on silica-gel sheets[13]. Cyclic AMP phosphodiesterase activity was determined at micromolar substrate concentration according to Thompson and Appleman[14], lactate dehydrogenase activity by the method of Wroblewski and LaDue[15], and protein by the method of Lowry *et al.*[16].

The levels of cyclic AMP in freshly dissected SCG of rats ranged from 1.9 to 4.2 pmol per ganglion, corresponding to 1.6 to 2.3 pmol per mg fresh tissue. If SCG were incubated for 5–10 min in the absence of drugs, only small amounts of cyclic AMP were detectable in the medium (Fig. 1). Adrenaline (10^{-4} M), noradrenaline (10^{-3} M), isoprenaline (10^{-5} M), and histamine (10^{-3} M) rapidly increased the levels of cylic AMP in SCG tissue in a dose-related manner. The time course of the accumulation of cyclic AMP on incubation with adrenaline is shown in Fig. 1.

Elevated cyclic AMP concentrations were observed in the medium after 3 min incubation of the ganglia with adrenaline (10^{-4} M) or histamine (10^{-3} M). The rise of the cyclic AMP concentration seemed to continue after the peak accumulation was reached in the ganglia but the medium levels decreased

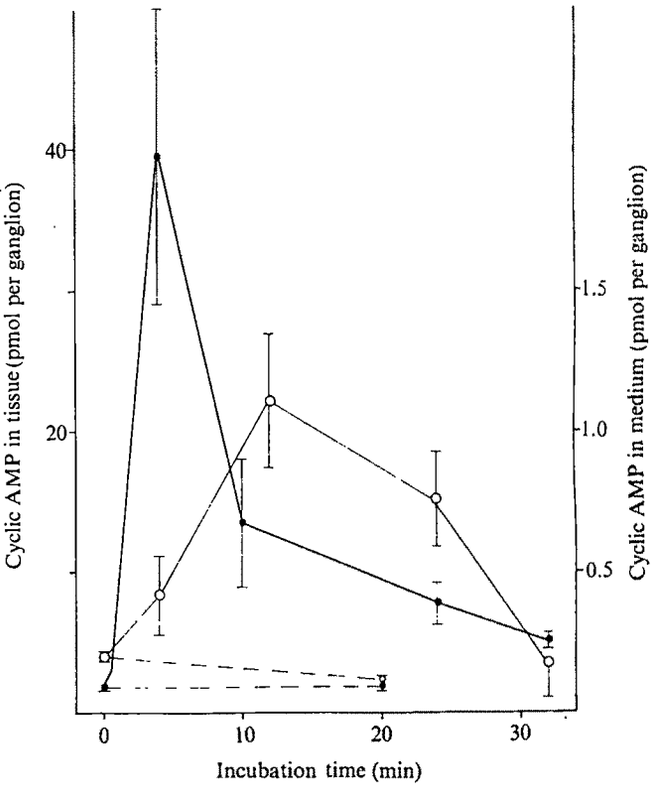

Fig. 1 Time course of the accumulation of cyclic AMP in superior cervical ganglia and in the incubation medium during incubation with L-adrenaline (10^{-4} M). Cyclic AMP was determined according to Gilman[11]. ●, Cyclic AMP content of ganglia; O, cyclic AMP appearing in the medium; - - - , time course in control incubations without the amine. Each point represents the mean of four experiments. Vertical bars show double standard errors of the mean.

again after 12 to 15 min of stimulation (Fig. 1). Acetylcholine (10^{-3} M) and carbamylcholine (10^{-9}–10^{-3} M) did not alter the cyclic AMP concentration in the SCG and in the incubation medium. Moreover, acetylcholine did not influence the accumulation and release of cyclic AMP induced by adrenaline. Preincubation with propanolol or practolol, two β-adrenergic blocking agents, completely blocked the effects of adrenaline on cyclic AMP in SCG and the medium (Table 1).

The assay for cyclic nucleotide phosphodiesterase activity in the incubation medium revealed the appearance of protein

Table 2 Medium content of total protein, cyclic nucleotide phosphodiesterase activity and lactate dehydrogenase activity after incubation of superior cervical ganglia for various times

Treatment	Protein (μg per ganglion)	Cyclic nucleotide phosphodiesterase (pmol cyclic AMP hydrolysed per mg protein per min)	Lactate dehydrogenase (mU per ml per mg protein per min)
Control (10 min)	11.5	13.5	7.4
Histamine 10^{-3} M (10 min)		6.7	5.3
Control (40 min)	9.6	12.0	24.3
Histamine 10^{-3} M (40 min)		4.8	18.7

and enzyme activity in the absence of stimulating drugs (Table 2). While the activity of lactate dehydrogenase which serves as a cytoplasmic marker enzyme increased in the medium during incubation with three- to four-fold increases from 10–60 min, bulk release of protein as well of phosphodiesterase activity occurred mainly during the initial period of incubation with in general no further increases in concentration and specific activity after 10 min of incubation. When ganglia were incubated with adrenaline or histamine the phosphodiesterase activity was not increased in the medium but slightly decreased while the total release of proteins from the ganglia into the medium was unchanged. This behaviour may indicate that cyclic nucleotide phosphodiesterase in an activated state is less prone to loss from intracellular compartments than in an inactive form.

After preincubation of SCG with ^{14}C-adenine for 60 min, less than 1% of the total radioactivity was found to correspond to ^{14}C-cyclic AMP. Of the total ^{14}C-cyclic AMP formed 35–45% appeared in the medium if measured after 15 min incubation in the absence of drugs. The addition of adrenaline or histamine strongly stimulated the rate of conversion to ^{14}C-cyclic AMP. Of the total radioactivity 6 and 5% was associated with cyclic AMP after incubation with adrenaline (10^{-4} M) and histamine (10^{-3} M) respectively for 15 min. The ratio of labelled cyclic AMP in the medium to ^{14}C-cyclic AMP in the ganglia remained essentially unchanged after stimulation as compared to the resting condition. This behaviour indicates that the preincubation with ^{14}C-adenine rather selectively labels a separate ATP precursor pool for cyclic AMP, as was observed earlier[12,17] and, in addition, suggests a membrane associated localisation of the precursor pool leading to preferential release of labelled product after the stimulation of adenylate cyclase by biogenic amines.

Our experiments have shown that from a peripheral sympathetic ganglion of the rat cyclic AMP is released following the stimulation of its intracellular formation by biogenic amines such as adrenaline and histamine *in vitro*. Acetylcholine neither affects the rate of synthesis nor the release of cyclic AMP. Whether under physiological conditions the release or overflow of cyclic AMP after stimulation by neurohormones serves to remove, and thus inactivate, excessive cyclic AMP unbound to protein kinases, or whether released cyclic AMP has some function of its own, is at present unclear. Evidence in favour of a release of cyclic AMP from central nervous tissues *in vivo* has also been obtained in humans[18].

Origins of metal ions in biology

A FERREDOXIN may have been one of the earliest proteins formed. The evidence for this assumption was recently presented by Hall *et al.*[1] based on the primary structures of several ferredoxins. Here, further evidence is reported for the early evolution of ferredoxins, and the origins of ferredoxins and other metalloproteins are discussed from an inorganic point of view based on thermodynamic data.

The atmosphere predominating during the time of chemical evolution and early life is generally assumed to have been a reducing one, characterised by a moderate pressure of methane (0.01–0.001 atm) and a very low oxygen pressure[2]. At such a reducing condition, thermodynamic data for the system, air–sea–sediment[3], indicate that at equilibrium the redox potentials in the seas were as low as −325 mV ($p^E = -5.5$): inorganic sulphur would be in the form of the iron sulphide, FeS_2(s) (pyrite), and perhaps partly as $Fe_{0.86}S$(s) (pyrrhotite); the major excess of iron would be in the form of Fe_3O_4(s) and a minor amount dissolved in the form of Fe^{2+} (≤ 0.2 mM).

Crystals of FeS_2(s) and $Fe_{0.86}S$(s) are well-known semiconductors having the capacity to transfer electrons. This leads to the following hypothesis: inorganic electron carriers in the form of FeS_2(s) and $Fe_{0.86}S$(s) were present prebiotically in the area where the first proteins evolved. When polypeptides containing cysteine residues formed, they reacted spontaneously with these iron sulphides forming bonds similar to those present in ferredoxins (compare refs 4–6). Also, iron in the form of Fe^{2+} would react forming iron proteins similar to rubredoxin[5]. Thus, very early, at least two different kinds of iron-sulphur proteins most likely formed, and these proteins probably developed independently into two different classes of electron carriers. It should be noted that during these reducing conditions low-valent molybden could enter solid solutions of iron sulphide (molybdenite, MoS_2(s), would be the prevailing molybden compound), and the sulphur-rich Mo-Fe proteins[7] might have evolved from such solid solutions (compare ref. 8).

The great abundance of iron in sea sediment supports the idea that the formation of iron-sulphur proteins was spontaneous and very common in early life processes. Also, the relative high concentration of dissolved iron (0.2 mM) would facilitate reactions with porphyrins, and thus the formation of haem proteins. Likewise, the Mn(II) concentration was much higher in the primordial seas[3], perhaps as high as 50 mM. This may explain why manganese seems to be one of the most important elements in early redox processes; for instance, in the photosynthesis of the primitive blue-green algae[9], and in the reactions of an early superoxy dismutase, apparently a manganese enzyme rather than a copper enzyme[10].

During the early reducing conditions, copper ions were most likely trapped into extremely insoluble Cu(I) sulphides; they could not be released into aqueous and biological phases until the air–sea–sediment system became more oxidised by evolving oxygen. Then copper proteins developed, such as plastocyanin and cytochrome oxidase, which were required for further biological evolution. It can be estimated, using Sillén's data[3,11], that Cu(I) complexes of thiols and amines could form at redox potentials of about +90 and +230 mV, and free Cu^{2+} at about +250 mV. Thus, thermodynamic data strongly support an evolution of metalloproteins, beginning with iron and manganese proteins and continuing with copper proteins.

When oxygen successively oxidised the air–sea–sediment quite insoluble phases of iron and manganese formed[3], FeOOH(s) and MnO_2(s). And at present, the concentrations of dissolved iron and manganese in sea water[12] are less than 10^{-7} M. Therefore, although copper was released by oxidation, iron and manganese became immobilised.

Also of particular evolutionary interest is the successive biological importance of weakly interacting metal ions; Mg^{2+} and Ca^{2+}, for instance. Magnesium ions are important in reactions simulating prebiotic condensations[13] and in early and fundamental cell reactions, such as protein biosynthesis, anaerobic energy production, and photosynthesis; calcium ions are of specific importance in processes characterising later and higher forms of life, such as nerve transmission, hormone secretion, and muscle contraction. One explanation for the early role of Mg^{2+} may be ascribed to its abundance; its high concentration in the oceans (54 mM) may have been even higher during the early reducing conditions, since on the primitive Earth NH^{+}_{4}, Fe^{2+}, and Mn^{2+} would partly replace Mg^{2+} in the silicate phases[3].

Artificial induction of the sexual cycle of *Neurospora crassa*

CHEMICAL regulation of sexual development in fungi was suggested in the 1880s by Sachs and de Bary (see ref. 1). Burgeff[2] later demonstrated that the so-called + and − strains of *Mucor mucedo* if separated by a colloidion membrane, produced zygophores that grew toward each other. The presence of diffusible substances which function in the sexual cycle has since been demonstrated in, for example, *Achlya*[1,3–8], *Allomyces*[9,10], *Ascobolus*[11–13], *Mucor*[14–20], *Saccharomyces*[21–23], and *Neurospora*[24–27]. Varied functions have been attributed to these extracts. In some well studied systems, such as *Achlya* and *Mucor*, chemical substances have been reported at almost all stages of sexual development, each serving to initiate the next stage[4,17].

But in spite of all this work relatively little is known about the chemical basis of the incompatibility of heterothallic fungi. Burgeff's work with *Mucor*[2], was confirmed in both *M. mucedo* and *Blakeslea trispora*[28]. In *N. crassa*, protoperithecia have been induced to develop into fruiting bodies, albeit sterile, by filtrates from cultures of the opposite mating type or from mated cultures[24]. Similar results have been obtained with lipid extracts from single and mated cultures of *N. crassa*[27], and from the resulting fruiting bodies a few ascospores were isolated which segregated in an aberrant manner with respect to the mating-type alleles. Unfortunately no tests for other genetic markers were reported.

Table 1 Effect of mycelial extracts from mated cultures on plates of pan 1 and leu 3 assessed by the presence of mature perithecia with spores.

Strain tested	Duration of mating before lysate extraction (h) 0	1	6	12	24	48	96	168	240	336

leu3a	−	−	−	+	+	+	+	+	−	−

−, No perithecia developed.
+, Perithecia developed.

These and similar reports gave rise to the suggestion that physical contact between compatible mating partners is not essential. Some diffusible substance, termed progamone by Plempel[29], induces the sexual cycle in a single strain. If the incompatibility block could thus be totally relieved, then artificial induction of a single strain should be followed by the orderly progression of sexual development. The conclusive demonstration of this induction would be the isolation of resulting ascospores which carry genetic markers from the single parent. This has never been reported, perhaps because the true incompatibility substances have not yet been isolated, or because artificial induction by these substances is followed by aberrant events in the ascogonium leading to strange segregation ratios, as Islam and Weijer[27] suggested.

It is significant that previous efforts to overcome incompatibility have relied largely on lipid extracts. Their incomplete success in inducing sexual development might indicate that incompatibility substances, if they exist, are not lipid in nature. Recent suggestions have been that some sex substances are proteinaceous[23,30,31]. We report here the effect of crude protein extracts on single mating cultures of *N. crassa*. They provide the first conclusive evidence of artificial indication of sexual development in a fungus.

Table 2 Average number of mature perithecia in leu3 plates treated with mycelial extracts.

	Duration of mating before lysate extraction (h) 0	1	6	12	24	48	96	168	240	336
No. of perithecia per plate	0	0	0	1,810	3,760	5,840	3,010	2,080	0	0

Figures represent the composites of five plates each.

Emerson strains, obtained from the Fungal Genetics Stock Center, Humbolt, California, provided the extracts. Single cultures were grown for 7 d in large flasks of standard crossing medium[32], fertilised with conidia of the opposite mating type and extracted at intervals ranging from 1 to 336 h later (Table 1). Extraction procedures were conducted at 4° C or less. Mycelial mats were homogenised in a Virtis blender with 0.15 M phosphate buffer followed by filtration through cheese cloth, to remove mycelial fragments, and subsequent centrifugation of the filtrate for 30 min at 25,0000*g*. The supernatant was dialysed against 0.05 M phosphate buffer, concentrated by pervaporation and filter sterilised. All extracts were tested to ensure the absence of viable material. Extracts were assayed by adding them to plates of single strain cultures of leu3 (allele *R*—156) and pan1 (allele 5531) and subsequent 14 d incubation at 25° C. Plates were then inspected for the presence of mature perithecia with spores.

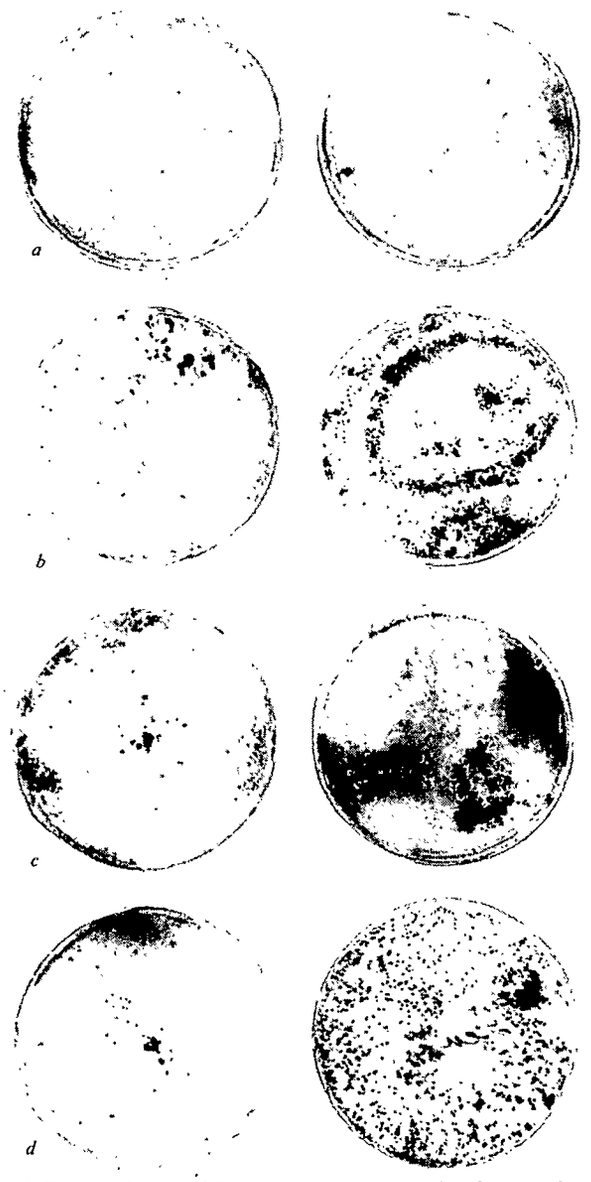

Fig. 1 Effect of mycelial extracts on unmated cultures of pan1 (left hand side) and leu3a (right hand side). *a*, Controls (buffer only added); *b*, with extract from 12 h culture of Em A × Em a; *c*, with extract from 96 h culture of Em A × Em a; *d*, with extract from 168 h culture of Em A × Em a.

The effect of the various mycelial extracts on single cultures of each of the mating types of leu3 and pan1 are shown in Tables 1 and 2 and illustrated in Fig. 1. Tetrads were isolated from mature perithecia obtained from eleven different plates (Tables 3 and 4).

The data in Table 1 indicate that the crude extract contains a sex factor capable of inducing the sexual cycle in a single mating culture of the heterothallic fungus. This substance is present in the mycelial extract of a mated culture; it appears first 12 h after mating and is no longer recoverable 240 h after mating. Preliminary investigations based on lack of activity in medium extracts, suggested that it is not a diffusible substance.

We have demonstrated further that after artificial induction sexual development proceeds normally, culminating in the production of mature ascospores which carry genetic markers from the single parent only (Tables 3 and 4). This is conclusive evidence of artificial induction. The isolation and purification of the active ingredient should ultimately provide the necessary clue to the chemical mechanism of incompatibility. The perithecia produced appear to be morphologically normal but some contain relatively few asci. The incidence of aborted spores (asci with four or eight aborted spores) does not seem to be significantly greater than in normal crosses. Some perithecia contained asci which showed a 4:4 segregation of genetic markers (Table 3). These may have been due to accidental fertilisation by contaminant wild type spores.

The sex inducer, termed erogen B in line with previous terminological suggestions[33], has not yet been characterised chemically. Preliminary tests based on its inactivation by heat and protease but not by nucleases indicate that it is a protein. It is interesting that the extracts from single mating cultures (unfertilised) are inactive in terms of their ability to induce the sexual cycle in strains of the opposite mating type. Thus, erogen B seems to be produced only when both mating types are present in the same culture. Similar results are reported in *B. trispora* and *M. mucedo* where trisporic acid synthesis is initiated only when living mycelia of both mating types are placed in the same culture and stops immediately if one of the partners is removed[34]. One might predict, from the simplest interpretation of a complementary stimulant model of the chemical mechanism of incompatibility, that the active ingredient, erogen B, from one mating type should successfully induce the opposite mating type. We suggest that the incompatibility mechanism is more complex and that another sex factor, erogen A, is involved. Further details of this work are bing published elsewhere.

Bacteria can swim without rotating flagellar filaments

THERE are two simple ways in which the observed screw-like propulsive motion of bacterial flagella can be understood. Either, first, the flagellum is like a rigid corkscrew rotating in a sort of journal bearing in the cell wall (hypothesis *A*) or, second, the flagellum is firmly attached to the cell wall and moves by the propagation of helical waves (hypothesis *B*).

Berg and Anderson[1] argue in favour of hypothesis *A*. Their most positive argument involves the idea that in multiflagellated bacteria a bivalent antibody firmly attaching itself to two neighbouring flagella would prevent motion according to hypothesis *A* but not on hypothesis *B*. Thus, they interpret the observations of Di Pierro and Doetsch[2] on the effect of univalent and bivalent flagellar antibodies on both peritrichous and uniflagellar bacteria as support for the 'rotating corkscrew' picture of flagellar motion.

Unfortunately, they have left out of their analysis a simple geometrical factor, which altogether removes from their argument the power to discriminate between the two hypotheses.

Figure 1 (based on Fig. 1 Berg and Anderson[1]) shows two cross-sectional views (Fig. 1*a* and *b*) along the helical axes of two neighbouring filaments at two successive instants of time according to hypotheses *A* and *B* respectively. In Fig. 1*a* the cross sections rotate, whereas in Fig. 1*b* they do not. The difference in pattern of relative motion of the spots marked on the surfaces of adjacent filaments is plain.

But now consider Fig. 1*a′* and *b′*, which show projected 'elevations' of the situations depicted in Fig. 1*a* and *b*. Again the spots are shown but on short segments of the neighbouring filaments in this view. Notice the relative motion of the spots in Fig. 1*b′* along the local filament axis, which is not apparent in the view in Fig. 1*b* alone. A bivalent antibody attached to the two spots in Fig. 1*b* and *b′* could therefore inhibit motion just as strongly as it could in Fig.

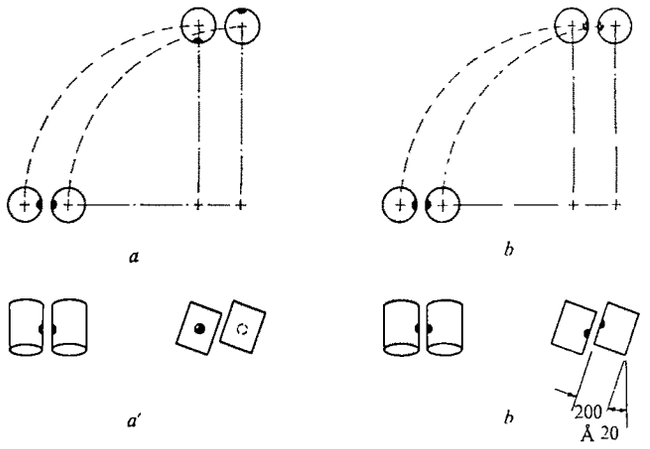

Fig. 1 A schematic view of two adjacent filaments rotating individually (*a* and *a′*) or propagating helical waves (*b* and *b′*) at two successive intervals of time, *a* and *b* Are sectional views in a plane normal to the helical axes (+). *a′* and *b′* Are elevations of segments of the filaments, projected from *a* and *b* in the plane of the helical axes.

1*a* and *a′*. The relative motion of the spots on hypothesis *B* is an oscillatory lengthwise rubbing, and we can estimate its amplitude easily by taking the helix angle in Fig. 1*b′* as about 20° and the diameter of the filaments as about 200Å, after Asakura[3]. Then the extreme displacement of one spot to another is ±70 Å, that is a total throw of 140 Å or about three times the diameter of a flagellin subunit.

Hence, the fact that bivalent flagellar antibodies 'lock' adjacent filaments can only be taken to rule out hypothesis *B* if the antibodies are flexible, and indeed much more flexible than seems likely from what is known about their size and construction.

Now antibodies have a Y-shaped form, with two arms which attach to the host at the tips[4]. From an X-ray crystallographic investigation of the Fab′ fragment of an antibody Padlan *et al.*[5] have determined its overall length to be 80 Å. Thus the length of an arm can be assumed to be about 70 Å. It seems likely that the tips are attached to the host with strong restrictions on the angle of attachment, and so it is difficult to see how such a molecule could stay attached to two points on adjacent flagella executing the large relative motion I have described without having extremely flexible arms.

The arguments of Berg and Anderson therefore do not prove that hypothesis *B* is wrong. Indeed, I believe hypothesis *B* to be correct because the propagation of helical waves in a filament requires only small relative movements between adjacent flagellin subunits, whereas a rigid-body motion of the entire filament would require a very specially constructed bearing. Moreover, as Klug[6] has pointed out, the problem of propagating a helical wave in a filament is largely subsumed in the problem of assembling a helical filament from identical flagellin subunits, which would still be an outstanding problem on hypothesis *A*.

I thank Dr A. Klug for help.

Toxicity of piperonyl butoxide to *Boophilus microplus*

SYNERGISM studies with the cattle tick *Boophilus microplus* have been effected by enclosing larvae in packets impregnated with olive oil solutions of the test chemicals and recording mortality after 48 h[1,2]. In these conditions larvae exposed continuously to 0.4% piperonyl butoxide were apparently unaffected. Subsequently, in studies to determine the sensitivities of the mixed function oxidase systems in organophosphorus (and carbamate) resistant and susceptible strains of *B. microplus*, larvae were immersed in aqueous colloids[3] of piperonyl butoxide. Concentrations greater than 0.02% proved to be toxic and an LC_{50} of 0.044% at 24 h after treatment was determined. This unexpected result aroused interest in the acaricidal potential of piperonyl butoxide. Although it is generally regarded as a nontoxic synergist[4], some workers have claimed it is toxic to houseflies at fairly high dosage[5] but others found it to be nontoxic[6]; toxicity to the mite *Acarus siro* (formerly *Tyroglyphus farinae*) has been recorded[7,8].

We decided that testing of the material alone and mixed with carbaryl, against parasitic stages of the tick in the field, was warranted. The mixture was tested because of the well known synergism of carbaryl and other carbamate insecticides by piperonyl butoxide against resistant houseflies. This synergistic action is believed to be due to piperonyl butoxide reducing the abnormally rapid rates of oxidative degradation of the carbamates by resistant flies[9]. The ticks used in our tests, however, were of the Biarra strain[10], and are resistant to carbaryl because of low sensitivity of their acetylcholinesterase to inhibition by carbaryl, while their detoxication systems are normal[11].

Cattle naturally infested with all stages of Biarra ticks were sprayed with aqueous emulsions of piperonyl butoxide formulated with one third its volume of Triton X-100. (*B. microplus* is a one-host tick with a cycle of approximately 21 d, and infested cattle normally carry mixed populations of larvae, nymphs and adults.) Cattle were also sprayed with a commercial wettable powder formulation of carbaryl at 0.3% active ingredient, and with mixtures of carbaryl and the piperonyl butoxide formulation. Counts of semiengorged females 4.5 mm to 8 mm in length were made at intervals up to 21 d after treatment and a survival index was calculated from counts of ticks on untreated control animals[12]. The results in Table 1 show that piperonyl butoxide is lethal to all stages of the tick when used at relatively high concentrations. The acaricide carbaryl allowed 28% survival of resistant Biarra ticks compared with 1% survival expected with susceptible Yeerongpilly ticks (W. J. R., unpublished data). With the addition of piperonyl butoxide at concentrations $\geq 0.3\%$, however, less than 1% of the resistant strain survived.

As much lower concentrations of piperonyl butoxide have been shown to inhibit the degradation of carbaryl in laboratory tests on larvae (C. A. S., unpublished data), this type of protective action doubtless contributed to the effectiveness of the spray mixtures. The lethal effect of piperonyl butoxide itself may also have contributed to the enhanced toxicity of the mixtures and it is not certain, therefore, whether piperonyl butoxide acts with carbaryl predominantly as a synergist or mainly as a toxicant participating in some type of joint action.

It seems likely that the toxic action of piperonyl butoxide resulted from inhibition of a mixed function or closely related oxidase, the recognised type of target of piperonyl butoxide[13]. This indicates that the cattle tick is vitally dependent on some part of this system. In support of this we have preliminary evidence that another methylenedioxyphenyl compound sulfoxide, which inhibits cattle tick mixed function oxidase, is also toxic.

The immediate significance of these findings is that an acaricide which had failed against a resistant strain has been restored to full effectiveness in the field by the addition of a compound which has no significant mammalian toxicity[14]. A more important aspect in the long term could be that from this class of compound a practical acaricide could emerge.

Table 1 Field control of the Biarra strain of cattle tick with sprays containing piperonyl butoxide or carbaryl or mixtures of the two chemicals

Spray Composition (%) Carbaryl	Piperonyl butoxide	Cattle per treatment	Survival index* on days† after treatment 1	2	5	7	9	12	14	16	19	21	Mean 1–21 days
–	0.03	4	99	64	92	132	52	105	86	42	36	38	75

Treehopper (Membracidae) alarm pheromones

ALARM pheromones are characteristic of many species of social Hymenoptera and Isoptera. The suggestion that alarm pheromones occur in gregarious, nonsocial arthropods[1] was confirmed by the report that the heteropteran *Dysdercus intermedius* Distant produces hex-2-en-1-al from its scent glands to repel members of its own species[2]. Aphids, other heteropterans which form aggregates on the plants on which they feed, also produce alarm pheromones. From specialised structures (cornicles) they secrete droplets[3] containing volatile pheromones that cause aggregates to disperse when attacked by predators[4] or parasites[5]. We now report alarm pheromones in three species of myrmecophilous treehoppers (Membracidae), two of which brood the egg mass (Fig. 1*a*) and all of which form feeding aggregates on their host plants (Fig. 1*b*). The release of these pheromones is unique in that specialised secretory structures are not involved.

Aggregations of *Vanduzeea arquata* (Say) on *Robinia pseudoacacia* L., and *Entylia bactriana* (Germar), and *Publilia concava* (Say) on *Ambrosia trifida* were studied in the field and laboratory. Whole treehoppers were crushed on 8-mm diameter filter paper disks which were held by fine forceps 1 cm from the centre of treehopper aggregations. A positive response was recorded when treehoppers moved at least 1 cm from their feeding sites on leaves within 1 min of presentation of the disk. In intra- and interspecific tests, at least five individuals were included in each trial and each combination was tested a minimum of five times. As a control, all test insects were exposed to untreated paper disks before testing with extracts. In field tests, responding individuals first raised their abdomens and expelled a droplet of honeydew from the anus before walking from their feeding sites, often moving to the opposite side of the leaf. Both nymphs and adults of all three species possessed repellent substances and each of the three species responded to compounds produced by the other two species (Table 1). Nymphs were more responsive to their conspecific pheromone than adults. Nearly all responding treehoppers reacted to treated disks within 20 s of initial exposure. No treehoppers responded to the untreated paper disks.

In further tests, filter paper disks treated with three to five drops of honeydew or haemolymph (collected by tibial excision) elicited no response from 63 treehoppers in eight aggregations. Only disks treated with a greenish milky fluid obtained by puncture of the body wall elicited a positive response from 42 of 63 test insects. We found no evidence of an external gland involved in the release of repellent substances. Treehoppers do not respond to cornicle droplets produced by several species of Aphidinae[6] or to synthetic aphid alarm pheromone, *trans*–*β*–farnesene, nor do aphids respond to the repellent substances from treehoppers.

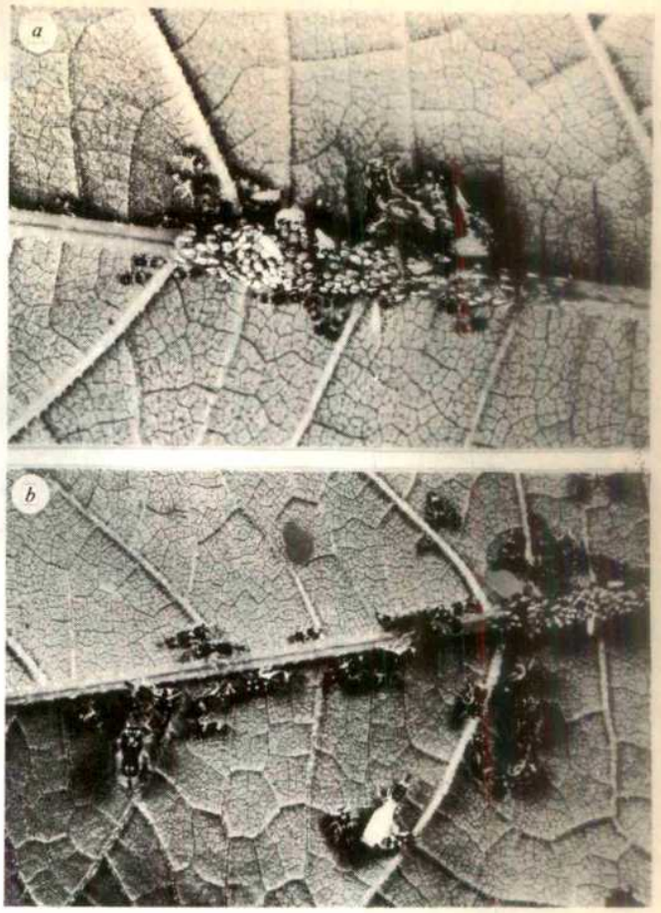

Fig. 1 Adult female *Entylia bacteriana* with her egg mass and recently hatched nymphs, (*a*). Aggregation of middle instar *Publilia concava* near egg mass (*b*).

Tests designed to determine if coccinellid predators would elicit the alarm response in attacked treehopper aggregations proved frustrating. Both larval and adult beetles usually avoided treehoppers, even when predators were starved 24 h before testing. In only two instances did larval coccinellids attack early instar treehoppers. After puncture of the body wall by the predator's mouth parts, alarm reactions were noted among other treehoppers which then relocated on the opposite side of the leaf.

Our results demonstrate that treehoppers produce alarm pheromone(s) which repel other members of the species. Treehoppers apparently cannot release the pheromone unless the body wall is punctured, such as by an attacking predator. Release of alarm substances in this manner has been described before for sea urchins[7] and certain species of schooling fishes[8,9]. It is not certain whether these compounds are specially elaborated pheromones or chemicals which also

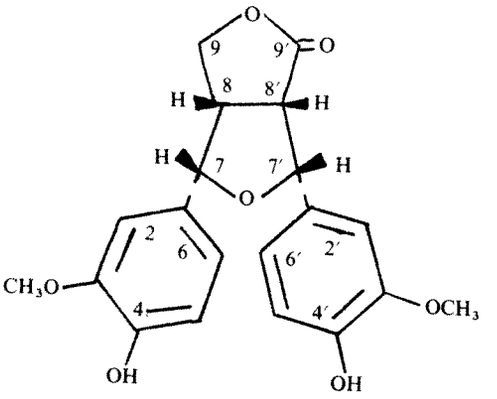
New germination inhibitor from *Aegilops ovata* L.

IT has been previously reported[1] that the dispersal units of *Aegilops ovata* L. contain a germination inhibitor. Leachates of the hulls inhibited the germination of *Lactuca* achenes. This inhibition was considerably stronger in light than in darkness, an unusual feature, since all germination inhibitors already described inhibit the germination of *Lactuca* achenes in darkness more than in light. We therefore felt it essential to isolate and characterise this specific inhibitor present in *Aegilops ovata*.



Preliminary investigations yielded a number of compounds namely vanillin, *p*-hydroxybenzaldehyde, ferulic, vanillic, *p*-hydroxybenzoic, *p*-coumaric and syringic acids. The inhibitory activity of these compounds did not, however, account for the initial inhibition observed with the crude extract. Repeated careful chromatography ultimately produced a pure fraction which showed the expected physiological activity. The compound in this fraction, obtained in pure form, was assigned structure (I) on the basis of its NMR, infrared and mass spectra. Structure (I) does not belong to any of the known groups of lignans[2], and is a monoepoxylignanolide (MEL), since the molecule has an epoxide as well as the five-membered ring lactone.

Table 1 Effect of mono-epoxylignanolide (MEL) on the germination of *Lactuca sativa* cv. "Great Lakes" achenes in light and in darkness at 25° C

Amount of MEL per filter paper (mg)	Light condition	Percentage germination* 24 h	48 h	72 h
1	L	0.5±0.5	10±3.7	20±4.2
	D	91.5±1.7	–	–
0	L	95 ±2.4	95.5±2.1	–
	D	95 ±0.6	95 ±0.6	–

L, In light; D, in darkness; *± standard error (4× 50 seeds)

The NMR spectrum of compound I shows the following signal pattern: 2,2′,5,5′,6, and 6′ H at δ6.80 (m, 6×H), 7 and 7′ H at 5.24 (d, 2×H, J=3.0 Hz, 8′ H at 3.40 (dd, J=9.0 and 3.0 Hz), 8 H at 3.18 (m), 9 H at δ4.1 (dq J_{ab}=10.0 Hz, J_{ax}=6.0 Hz and J_{bx}=4.0 Hz), C(3) and C(3′) —OCH_3 groups at δ3.78 (s, 6×H). The two phenolic –OH protons

Compound I

at C(4) and C(4′) are at δ5.80 disappearing on exchange with D_2O. The fragmentation pattern in the mass spectrum contributed to the elucidation of the structure. The loss of fragments m/e 84 and 85 from the molecular ion peak (M^+ 372) correspond to the five-membered ring lactone. In addition the fragments m/e 151 and 137 (base peaks) arise from the loss of $\dot{O} \equiv C.C_6H_4(OCH_3)$ (OH) and $H_2\dot{C}.C_6H_3(OCH_3)$ (OH) respectively. The presence of a five-membered ring lactone in compound I was further substantiated by its infrared spectrum, ν_{max} 1,770 cm^{-1} characteristic of such a system[3].

For the biological assay Whatman No. 1. (diameter 52 mm) filter papers were impregnated with 1 mg quantities of the pure substance. After careful evaporation of the solvent each filter paper was placed in a Petri dish covered with an untreated filter paper and distilled water (2 ml) added. After equilibration over 3 h, 50 achenes of *Lactuca sativa* cv. "Great Lakes" were introduced and the Petri dish kept in a germinator at 25° C either in continuous white light or in darkness. Each test (four replicates) was monitored by a blank (four replicates) in which the lower filter paper was untreated.

The results (Table 1) clearly indicate that the MEL has a unique activity in that it inhibits germination in white light (fluorescent and incandescent) while it is inactive in darkness. This is the first instance to be reported where a compound has such a property. The inhibitory activity of MEL in white light, however, diminishes with time.

Dry deposition of sulphur dioxide on wheat

ABOUT 6 million tonnes of sulphur dioxide (SO_2) are emitted annually into the atmosphere over Britain. Atmospheric concentrations and the quantity of SO_2 exported are determined by the rates of emission, dispersal and removal. Removal as sulphate by rainfall over Britain accounts for about 15% only of annual emission[1]. As long ago as 1950 Meetham[2] suggested that turbulent transfer was an important process for removing SO_2 molecules at the Earth's surface, a process usually referred to as 'dry deposition' even when the surface is wet. Measurements of the dry deposition rates on short grass and water have not been made until recently[3,4]. From limited evidence for short grass Garland *et al.*[1] suggested that dry deposition over Britain may remove 40% of the SO_2 emitted annually. The surface factors which may control dry deposition rates have not yet been established, however, nor have dry deposition rates on field crops been measured, although it has been suggested that the sulphur supplied in this way may avoid deficiences on some British soils[5]. Here we report the results of an extensive series of measurements of dry deposition rates on a field of winter wheat and point to factors which may limit the deposition rate.

Table 1 Characteristic measurements of the resistances to deposition of sulphur dioxide on wheat. The SO_2 concentration χ and deposition velocity v_g are referred to $z = 1$ m.

Date	Time (GMT)	v_g mm s^{-1}	χ μg m^{-3}	$r_a + r_c$ s mm^{-1}	r_c s mm^{-1}	Wet (W) or dry (D)

Because the surface is a sink for SO_2 the volume concentration χ decreases towards the surface and the flux F of SO_2 may be determined from measurements of the variation of concentration with height using the standard micrometeorological equation

$$F = K(z) \frac{\partial \chi}{\partial z}$$

where $K(z)$ is the eddy diffusivity for SO_2 at height z, assumed equal to that for momentum. At Sutton Bonington, 10 miles south of Nottingham, values of χ were measured at five heights up to 2 m over a uniform 8 ha field of winter wheat (var Maris Ranger) using the techniques described by Garland *et al.*[1]. Eddy diffusivities corrected where necessary for the effects of atmospheric stability[6] were determined from analysis of wind speed and temperature profiles in the lowest 2 m of the atmosphere.

Deposition rates are often characterised by the velocity of deposition v_g defined by $v_g(z) = \frac{F}{\chi(z)}$ as this quantity is independent of concentration, but to investigate the controlling factors in the deposition process it is convenient to consider the resistance to deposition, $r = \frac{1}{v_g}$ as the sum of an aerodynamic resistance r_a and a surface resistance r_c. The surface resistance is a measure of the affinity of the surface for SO_2 uptake, that is $r_c = 0$ for a perfect sink. Values of r_a were calculated from wind and temperature profiles making allowance for the different processes responsible for mass and momentum transfer at the surface of foliage[7]. The accuracy of the values of v_g depends mainly on the gradient of SO_2 concentration. The chemical analysis was accurate to about ± 0.5 μg^{-3} SO_2 and the uncertainty in v_g ranged from about $\pm 5\%$ to $\pm 50\%$.

Measurements were made over 1 or 2 h intervals during the period from June 8 until August 12, 1973, which may be arbitrarily divided. Before the last week in July most of the leaves were green and the crop was growing. By the first week in August, the crop was senescent and it was harvested on August 13.

Table 1 shows characteristic results of measurements before and after senescence. The large proportion of the total deposition resistance $r_a + r_c$ contributed by the surface resistance r_c clearly indicates that surface processes limit dry deposition rates in most conditions. When the crop was fully senescent, two regimes were distinguished. When the leaves were dry the SO_2 concentration gradient was generally below the limit of detection, that is $\delta\chi/\delta z < 0.5$ μg^{-3} m^{-1}. This implies that v_g was very small (< 0.8 mm s^{-1}) because the surface resistance was large (> 1.2 s mm^{-1}). There were eight occasions when this occurred but none before August 3. In the late evening the leaves were frequently wetted by dew and the values of r_c decreased substantially. The effect of dew was also observed before senescence, indicating that for wet crops, physiological control of deposition was unimportant. On several occasions when measurements continued sequentially over 24 h the variations in r_c and v_g reveal some interesting features.

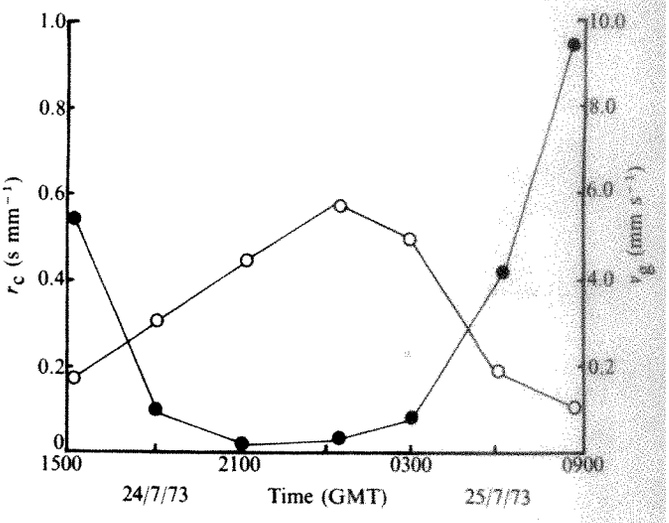

Fig. 1 Variation with time of the deposition velocity v_g (○) and surface resistance r_c (●) for sulphur dioxide on wheat.

Figure 1 shows the diurnal variation of r_c and v_g on July 24. At 1600 h GMT, values of r_c were representative for a dry crop. By 1800 h, dew could be detected on the flag leaves of the crop and the value of r_c was decreasing. As dewfall continued r_c decreased until midnight but then began to increase although dew was still present. The changes in r_c may be explained by a decrease in *p*H of the dew which decreases the solubility of SO_2 (ref. 8). A similar variation of r_c with time in the presence of dew has been observed in other 24 h experiments. On a night with strong winds and cloud, and consequently no dew, however, r_c remained fairly constant with time.

The mean v_g from 12 occasions when the crop was wet was 4.0 ± 1.4 mm s^{-1} and the corresponding mean for r_c was 0.14 ± 0.12 s mm^{-1}. For 16 occasions when the crop was dry but physiologically active the mean values of v_g and r_c were 3.3 ± 2.0 mm s^{-1} and 0.40 ± 0.26 s mm^{-1} respectively. The values of v_g and r_c do not differ significantly, but the former is considerably below the value of 8.5 mm s^{-1} for the mean deposition velocity to short grass[1]. By extrapolating a mean value of v_g, Garland *et al.*[1] calculated that the annual dry deposition of SO_2 over Britain was 110 kg ha^{-1}, assuming a mean concentration of 40 μg^{-3}. If our mean value for v_g (3.6 mm s^{-1}) is more representative of arable crops then with the same assumptions it implies an annual SO_2 deposition of about 47 kg ha^{-1}.

Our results indicate that surface wetness has a major influence on dry deposition rates and that the surface resistance is the controlling step in deposition to vegetated surfaces. A further implication is that in winter, when surfaces are wet for long periods, dry deposition rates of SO_2 may be considerably enhanced.

We thank the Central Electricity Generating Board for a grant and A. Martin, J. L. Monteith, J. Shepherd and staff of the Environmental Sciences Division, Harwell, for assistance and discussions.

Two spot ladybirds as indicators of intense local air pollution

Most individuals of the two spot ladybird, *Adalia bipunctata*, may be designated as red with black spots, or as black with red spots. Although intermediate forms are found, they usually constitute less than 1% of the population in Britain. The most commonly occurring black forms are under the control of a single gene and are genetically dominant over the red forms[1]. In parts of continental Europe[2] and in Britain[3,4], the frequency of black is highest in industrial and other areas with much atmospheric pollution; up to 97% melanics are found in Liverpool and Glasgow. Multiple regression analysis suggests that there is an association of high melanic frequency with smoke, but not with sulphur dioxide[5], this conclusion is supported by results from Birmingham, where melanic frequencies fell soon after the introduction of extensive smoke control areas, which had only a relatively small effect on sulphur dioxide levels[6].

Samples previously reported from South Wales[3] indicate a consistently low melanic frequency, the maximum being 6% in a sample of 35 individuals from Pontypridd. This is in accord with the occurrence of generally low levels of smoke pollution, in spite of considerable industrialisation[7].

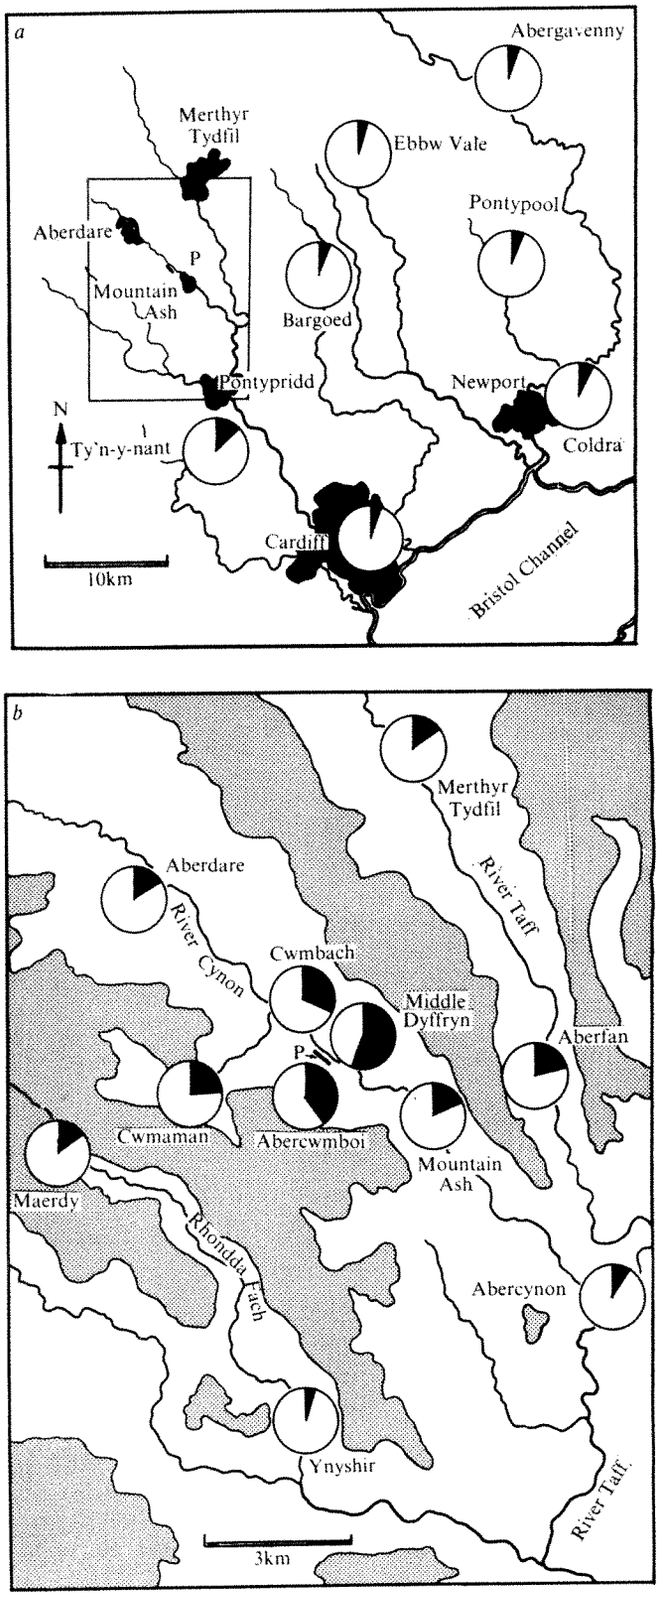

Fig. 1*a* Map of the eastern valleys of South Wales showing the position of the Phurnacite plant (P), the melanic frequencies at the more distant sampling sites and the area shown in detail in *b*. The relative size of the black segments is proportional to melanic frequency. *b*, Map of the Cynon Valley showing melanic frequencies. For clarity, the Aberewmboi and Middle Dyffryn sites are shown at greater than their true distance (0.3 km) from P ⊙ Ground over 1,000 feet above sea level is stippled.

A sample of 95 *Adalia bipunctata* was obtained from the Cynon valley in June 1973, however, of which 53.7% were black. The ladybirds were found on sallow (*Salix* spp.) and stinging nettle (*Urtica dioica*) over an area of about 75 m × 20 m. The site is in the ruins of the Middle Dyffryn colliery and is 300 m to the east of the ovens of the National Coal Products Phurnacite plant at Abercwmboi, which produces smokeless fuel from coal; it is on the edge of the wood in which the effects of air pollution on the leaves of oak trees were investigated[8].

To discover how extensive was the area of relatively high melanic frequency, samples were collected from other sites in this part of South Wales (Fig. 1); the results are summarised in Table 1. The sample from the village of Abercwmboi, with 41.5% melanics, was obtained roughly the same distance from the ovens as the first sample, but to the west of them. The difference in frequency between the two samples does not quite reach formal significance; $\chi_1^2 = 3.78$, $P = 0.052$. The melanic frequency falls steadily with increasing distance from the Phurnacite plant (Fig. 2), and there is no indication that other areas with locally high frequencies occur in South Wales. The site at Ebbw Vale (2.8% black) is 200 m from large steel and tinplate works, and that at Ty'n-y-nant (10.7% black) is 500 m from coke ovens and chemical works which are, however, much smaller than the Phurnacite plant, but may be responsible for the apparent small increase in melanic frequency.

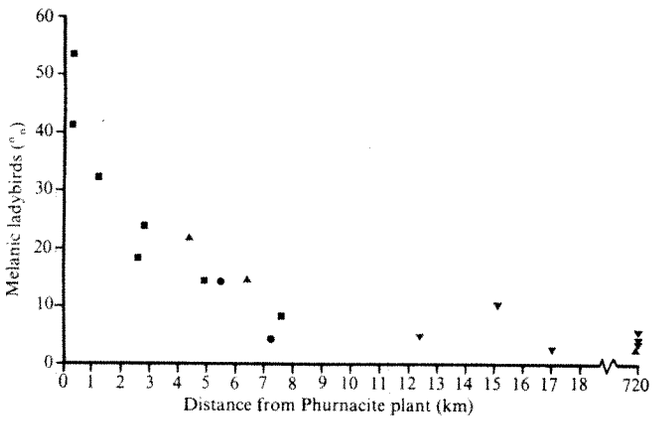

Fig. 2 The relationship between melanic frequency in samples of *Adalia bipunctata* and the distance of the collecting site from the Phurnacite plant at Abercwmboi. ■, Sites in the Cynon valley; ●, sites in the Rhondda Fach; ▲, sites in the Taff valley; ▼, other sites in south east Wales.

There is extensive damage to the trees near to the Phurnacite plant, but this is largely confined to those on the east side, the prevailing winds being westerly. Williams *et al.*[8] concluded however that, although sulphur dioxide was having a marked effect on the trees, high sulphur levels in the leaves resulted from increased epidermal permeability caused by fine particles in the pores of the stomata, rather than from locally high levels of atmospheric sulphur dioxide. Both sulphur dioxide and smoke have lower mean annual levels at a recording point 1.3 km to the ESE of the Phurnacite plant (44 $\mu g\ m^{-3}$ and 30 $\mu g\ m^{-3}$ respectively) than in the urban areas of Mountain Ash (49 $\mu g\ m^{-3}$ and 55 $\mu g\ m^{-3}$) 2.1 km to the south-east, and Aberdare (60 $\mu g\ m^{-3}$ and 41 $\mu g\ m^{-3}$) 4 km to the north-west; but the fallout of particulate matter or grit is very much higher immediately to the east of the Phurnacite plant than elsewhere. In 1967 (the most recent year for which almost complete records are available) total solids at the Middle Dyffryn site were 2.16 $g\ m^{-2}\ d^{-1}$, compared with 0.21 $g\ m^{-2}\ d^{-1}$ at Abercwmboi (from data supplied by Dr J. Ll. Williams). This high level of particulate matter renders it impossible to use the biological method of smoke and sulphur dioxide assessment[9] to provide a more detailed comparison of melanic frequencies and air pollution, for I had taken care to avoid proximity to sources of intense pollution. Although I found the reflectance of tree trunks to be the most important single indicator of sulphur dioxide levels over southern Britain, reflectance near the Phurnacite plant is largely influenced by the amount of particulate matter deposited on the surface. The other biological parameters used suggest that both mean smoke and sulphur dioxide levels are lower at the Middle Dyffryn site than in Mountain Ash.

If air pollution from the Purnacite plant has a direct selective effect on the melanic frequencies, then it seems to be an effect of gases, other than sulphur dioxide, or of the particulate matter comprising grit and smoke. At Aberfan, a melanic frequency of over 20% is found 4.3 km from Middle Dyffryn, and separated from it by high ground on which the insect does not occur; furthermore, the decline in melanic frequency with increasing distance from the Phurnacite plant seems to be the same in samples from the Rhondda Fach and Taff valleys as it is in the Cynon valley (Fig. 2). This suggests that the frequencies are influenced not only by outward gene flow, but also by the Phurnacite plant possibly having an appreciable effect over such distances.

I thank Richard Steward and Dr D. R. Lees for their help with various aspects of this work, and Dr J. Ll. Williams, Medical Officer of Health for Mountain Ash and Aberdare, for the data on pollution levels. The work was supported by a grant from the Nuffield Foundation.

Deltatheroides–like mammals from the Upper Cretaceous of North America

THE family Deltatheridiidae[1] has been redifined to include primitive therian mammals of tribosphenic grade referrable to only two genera *Deltatheridium*[1] and *Deltatheroides*[2], from the Djadokhta and Barun Goyot Formations, of uncertain age within the Upper Cretaceous of Mongolia[2]. The Deltatheridiidae, long considered Eutheria, although of disputed taxonomic dimensions and phyletic position within the infraclass[1–5], seem now best classified as therians of metatherian–eutherian grade, but referrable to neither Metatheria nor Eutheria[2]. A combination of apparent marsupial-like and placental-like features in the known parts of the dentition and skull of members of the Deltatheridiidae insures that the family will be of continuing interest.

I here record the first recognition of the Deltatheridiidae *sensu* Butler and Kielan-Jaworowska[2] from territories outside of Asia, an occurrence documented by fossils collected at Upper Cretaceous horizons in the Western Interior of North America. The new deltatheridiids are known only from isolated teeth and tooth fragments, which have been found but rarely in the large samples of North American late Cretaceous mammals in collections. Nevertheless, the detailed resemblances of these fossils to molars of the Asiatic Deltatheridiidae, especially to those of *Deltatheroides cretacicus*[1], make reliable the identifications recorded here. The fossils are: (1) University of Alberta (UA) no. 4085b (see Fig. 1*a*), a single upper molariform tooth from the late Maestrichtian (Lancian)[6,7] Upper Edmonton Formation, Alberta, and first described[8] as a possible deciduous P^4 of the palaeoryctid *Cimolestes magnus*[9]; (2) University of California (Berkeley) Museum of Paleontology no. 46359, a lower molar (see Fig. 1*b*), and American Museum of Natural History no. 59482, a lower molar trigonid, both from a previously unidentified species occurring in the late Maestrichtian Lance Formation, Wyoming[10]; and (3) UA 4248, a previously unidentified lower molar talonid, from the late Campanian (Judithian)[6,7] Oldman Formation, Alberta. The Lance and Oldman specimens are virtually identical in coronal architecture, other than slightly larger size, to M_2 or M_3 of *Deltatheroides cretacicus* (this species is being redescribed elsewhere by Z. Kielan-Jaworowska). Occlusal relations and comparison with upper molars of the Asiatic deltatheridiids suggest that the tooth from the Upper Edmonton Formation is probably an M^1 from the same or closely related species as are the lower molar specimens.

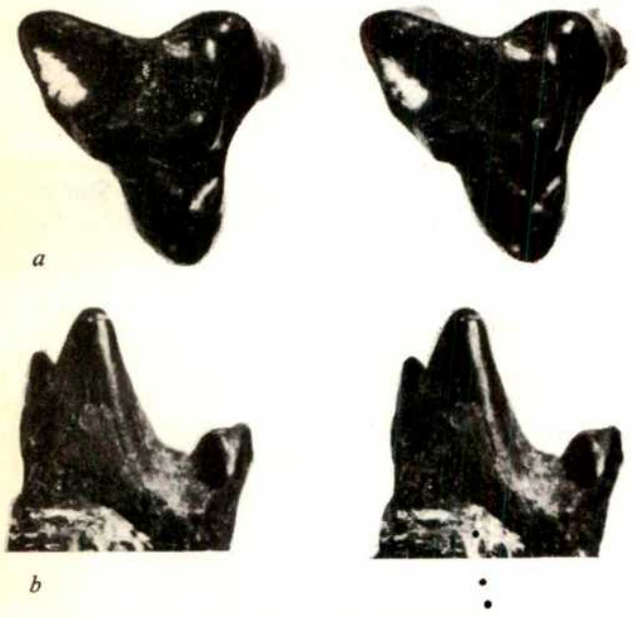

Fig. 1 Stereophoto pairs of isolated molars of cf. *Deltatheroides sp.*, Upper Cretaceous, North America. *a*, UA 4085b, M^1 (?), Upper Edmonton Formation, Alberta, Canada; *b*, UCMP 46359, lower molar, Lance Formation, Wyoming (×about 7.6).

The close morphological resemblances between the North American and the Asian fossils generate inferences that: (1) the known Asian and North American deltatheridiids diverged relatively recently before their oldest discovered occurrences in the Djadokhta and Oldman Formations; and, as a corollary, (2) migration of the descendant deltatheridiid species from Asia to North America or *vice versa* (and the known evidence does not now permit a choice) took place soon after this divergence. Although these inferences concerning the near contemporaneity of earliest appearances of Asiatic and North American deltatheridiids must remain tentative—at least until more extensive sampling of the local mammalian faunas of North America and East Asia can be completed—they are nevertheless in accord with other evidence that had earlier and independently indicated the improbability of a relatively great Cretaceous age of the Djadokhta mammals[11]: relict triconodonts and symmetrodonts survived in North America to at least as late as the time of deposition of the early Campanian (Aquilan)[6,7] Upper Milk River Formation (still before the time of first appearance of North American deltatheridiids), but fossils of neither triconodonts nor symmetrodonts have been found in the deltatheridiid-bearing Djadokhta Formation or in younger Upper Cretaceous rocks in East Asia.

W. Clemens, A. Crompton, Z. Kielan-Jaworowska, M. McKenna and B. Slaughter permitted study of specimens in their care; A. Lindoe photographed the specimens; and D. Krause critically read the manuscript. This work was supported by the National Research Council of Canada and the University of Alberta.

Precision Instruments

Polarimeter Model A

This instrument gives the highest degree of accuracy with divided circle on glass reading to 0.01 degree.

Circle centre on ball bearings · Easily removable trough · Divided drum replacing verniers · Stationary observation telescope · Circle reader enlarging image of scale · Slow motion adjustment always in action · Suitable, with additions, for measurement of rotatory dispersion.

This polarimeter has been supplied in large numbers both in this country and abroad, and has always been acclaimed as being of advanced design and workmanship. Please ask for particulars "N".

We now have capacity for aluminising certain types of mirrors, at short notice.

Prehistoric snails

Land Snails in Archaeology, with Special Reference to the British Isles. By John G. Evans. Ppxii+436. (Seminar: New York and London, January 1973.) £7.90.

ARCHAEOLOGISTS are becoming increasingly interested in the reconstruction of the environment and ecology of the ancient sites they excavate, and one of the sources of evidence available to them is the careful study of the shells of ancient land snails. These are particularly important in the limestone and chalk regions of Britain where pollen grains do not survive to give direct evidence of the local flora.

This book sets out to give an account of the growth of interest in the study of land snails by archaeologists during the past century, the methods of identification and the results that can be achieved by careful sampling and interpretation.

The possibility of using snail shells as environmental indicators was first suggested by General Pitt-Rivers when he found their remains in the ditch of the iron age hill fort at Cissbury, Sussex, in 1869. Most of the early work on snails in ancient contexts in this country was carried out by A. S. Kennard and B. B. Woodward. Recent developments largely brought about by the author of this book, and recorded in detail in it, include the much more accurate sampling procedures, the interpretation of the environment from the standpoint of both moisture and temperature. "The techniques of snail shell analysis is now refined to the extent that we are able to recognise and differentiate between the effects of climatic, local environmental and anthropogenic influences on ancient snail populations."

Now it is essential that further study be made of the geographical ranges of present day snail populations in this country. Also urgently needed are quantitative data on modern snail populations from habitats whose physical, chemical and biological aspects are fully described. The reconstruction of the past environment depends on establishing the snail fauna of the locality: snail faunas in which 90% of the snails are of one species reflect a severe habitat—salt marsh, ploughed field or sand dune. A wide range of species may be found in well established woodland—upwards of fifty species is not uncommon, with none of them accounting for more than 15% of the total fauna.

The study of snail faunas ultimately rests on the identification of the remains of the snail shells surviving from the past. The author provides a number of pages of outline drawings of the 200 species involved, including illustrations of immature forms, which should be a splendid guide for those undertaking this identification work. It might have also been helpful to supplement this with photographs both of complete shells, and the most common ways in which they survive as fragments. The species are described in detail, with the environment, distribution and archaeological finds all listed for each species.

Chapter six deals with the ecological groups into which snail faunas may be classified, and may be one of the most interesting sections of the book for those concerned with reconstructing past ecological conditions. They are divided up into shade-loving species, (including the Zonitidae, *Carychium tridentum* and *Discus rotundus* and other woodland species); intermediate or catholic species; open country species (including *Vertigo pygmaea, Pupilla muscorum, Vallonia costata, V. excentrica* and *Helicella itala*); marsh and freshwater slum species. Besides these, four other groups which are not entirely ecological can be distinguished: alien species (introduced into Britain by man at various times since the Bronze Age), burrowing species (*Pomatias elegans* and *Cecilioides acicula* in particular), anthropohobic species, confined to wild habitats in remote woodland (including *Lauria angelica, Ena montana, Helicodonta obvoluta* and *Limax tenellus*); and synanthropic species which live in man made habitats such as gardens, hedgerows and refuse heaps (for example, *Hygromia striolata, Helix aspersa* and *Limax flavus*).

Some snail species are now extinct, which were relatively common in the Boreal period, and thus may be useful for giving some clue for dating the deposits in which they occur, in particular *Vertigo genesii* and *Discus ruderatus*.

The conclusions from work so far are that there was an all-pervading forest cover in Mesolithic and Neolithic times, and that forest clearance at a number of Neolithic sites was followed by a period, immediately before the burial of the soil profile, of short turfed grassland. So far snails have not indicated cultivation, except at South Street, Avebury where the ground was ploughed in Beaker times, possibly to create better grazing land. Regeneration of the forests seems to have been prevented for many centuries, probably by grazing, and was never very successful. In the latter half of the first millenium BC the Iron Age farmers began to bring the chalk and limestone soils into more intensive cultivation.

This book marks the beginning of a new phase in the study of ancient land snails, where carefully controlled sampling and analysis can provide the data for the reconstruction of snail faunas, and thus of ancient environments. There are some problems to be overcome, notably the lack of adequate information about some of the modern snail populations, and the fact that some snail species seem to undergo changes in habitat preference (for example *Vallonia costata* and *Hellicella itala* which occurred abundantly in prehistoric arable habitats, but are absent from cultivated soils today). It is also possible that some habitats known in the past are now quite extinct.

Land Snails in Archaeology should be on the shelf of every practical archaeologist, and of all those interested in reconstructing the past environments of ancient sites.

JANE M. RENFREW

Mermaid morphology

Morphology of the Sirenia: A Macroscopic and X-ray Atlas of the Osteology of Recent Species. By Hans E. Kaiser. Pp. viii+76. (Karger: Basel, London and New York, 1974.) Sfr.94; £13.65; $29.15.

THE true function of this slim but expensive book of photographs is somewhat difficult to discern, though much effort has gone into its production. Here is an ordered series of original photographs, together with a number of positive X-ray photographs, designed to illustrate the macroscopic osteology of the three genera of modern Sirenia. Each photograph is accompanied by a detailed textual description of what is to be seen in that particular picture. But unfortunately a number of the photographs are lacking

CHAPMAN & HALL,

Ecological Stability
Edited by M. B. USHER and M. H. WILLIAMSON
May 1974: 208 pages: illustrated: hardback: £3.60
The unifying theme of this book is in the analytic investigations of populations, the quantification of population processes and the application of mathematical models to simulate and predict these phenomena. The chapters are based on, but are not identical to, twelve papers given at a 'workshop' meeting at York University in the summer of 1973. The papers fall into four inter-related groups: relations between predator and prey; relations between host and parasite; relations of species within a trophic level; and the effects of special heterogeneity on the stability of species.

CHEMISTRY TEXTBOOK SERIES
Pericyclic Reactions
G. B. GILL and M. R. WILLIS
April 1974: 248 pages: limp cover: £2.95
This book provides a comprehensive introduction to the main theories that have been advanced to explain the stereospecificity of pericyclic reactions. It has been written for use as a text for both undergraduate and postgraduate courses; there are worked examples, formal problems with solutions, and references to the review literature.

The Chemistry of the Non-Metals
P. POWELL and P. L. TIMMS
April 1974: 274 pages: illustrated: limp cover: £2.85
This undergraduate level textbook is concerned with the non-metallic elements and the compounds they form with one another. An attempt is made to correlate the chemistry of these compounds as a whole and emphasis is given to discussing common features of structure and bonding within the different classes of compound.

Further information on these titles and a list of stockists is available from the publishers on request.

in clarity, and others are marred by the excessive prominence of the wire ties holding the specimen together. Additionally there are a few line drawings of ossicles, vestigial pelvic bones and so on. But nowhere are scales or measurements indicated except in the initial photograph of the mounted skeletons of *Hydrodamalis*, *Dugong* and *Trichechus* where the overall lengths are stated.

Description is entirely dominant over discussion and comment. The author evidently has little interest in the extraordinary and changing tooth patterns in the dugong and manatee in the course of the life of the individual: pointers on certain pictures simply say "Dentes molares". The non-erupting tusks of the female dugong are nowhere referred to, nor the presence, form and function of the horny buccal pads which are so important in the Sirenia. The work is based on several specimens and not upon series, of skulls, for example.

G. C. L. BERTRAM

International eel

Der Aal: Biologie und Fischerei. By Friedrich-Wilhelm Tesch. Pp. 306. (Parey: Hamburg and Berlin, 1973.) DM 78.

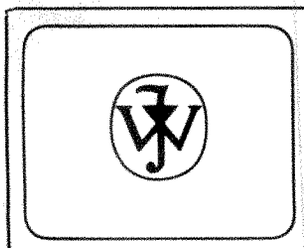
THE physiology and migrations of eels raise fundamental and controversial research questions. This book will give a further impetus to work in this field, for it surveys the entire literature (about 900 references) dealing with the Atlantic as well as the Indopacific species of Anguillidae.

Two-thirds of the book are devoted to zoological aspects, with an especially thorough discussion of anatomy, variation, taxonomy, life history, feeding and migrations. The separation of two Atlantic species, the American, *Anguilla rostrata* and the European, *A. anguilla* is defended against the background of a recent controversy. Dr Tesch attributes their geographical separation to the time required for the transition from larva to elver. The European species requires for this three years, so that larvae brought prematurely near American shores will not be ready to respond by movement to freshwater. American larvae become elvers in one year and any transported eastwards will perish as they will not be near the coast at the appropriate ontogenetic stage.

The chapters on environmental influences on productivity of inland waters, growth, behaviour and even sex determination and sex ratios are particularly detailed. Certain current biochemical studies, however, are not discussed in sufficient detail (and Sick's haemoglobin studies were electrophoretic not chromatographic, page 41).

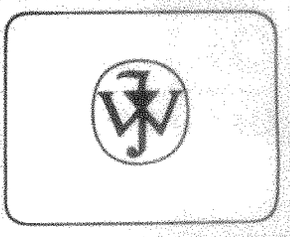
In addition to the main body of information, minor but fascinating issues are not forgotten: the methods and difficulties of determining age and sex of specimens, the poison in the uncooked eel blood, the survival of a specimen with very little haemoglobin, the swimming ability of the larva, and so on.

The last third of the book deals expertly with methods of fishing and other related issues. The increasing economic importance of the eel is clearly demonstrated. Characteristically, for our age, the collection of elvers for food and the impediments to elver immigration presented by technical works, are leading in Japan to scarcity of eels. This is met by fish farming, and there are over 1,200 eel farms in that country. The methods used in these are described.



This is an excellent book, impeccably produced and with very helpful illustrations and tables. I hope that it will be translated into English.

E. M. PANTELOURIS



insects in flight
WERNER NACHTIGALL
The current knowledge and latest research findings in the biophysics of insect flight are combined in this book and explained in a way that is clear to the general reader without neglecting accuracy of detail. The author describes the fascinating inventiveness of Nature, revealing the multiplicity and intricacy of her designs. The book contains a large number of illustrations and unique photographs.

WILEY INTERSCIENCE

CLINICAL ONCOLOGY: A Quantitative Approach

By **N. M. Emanuel** and **L. S. Evseenko,** *Meditsina Publishing House, Moscow.*

This monograph deals with the application of some methods of kinetics and statistics in various fields of clinical oncology, a subject which is of topical interest. Every pathological process, including tumours, develops in time and therefore the laws of kinetics, which examine the mechanisms and development of different processes, create new prospectives in oncology for theoretical analysis and practical work. (*Translated from the Russian*).

April 1974 280 pages £11.25

MOLECULAR MICROBIOLOGY

Edited by **J. B. G. Kwapinski,** *University of Manitoba.*

A new approach to the chemistry and structure of micro-organisms. Describes micro-organisms in terms of their constitutional and dynamic molecular components and views them as dynamic assemblies of specific macromolecules that constantly interact among themselves and with the environment. Divided into two major parts: a general treatment of properties and function of microbial molecules; and a systematic description of molecular constitutions and interactions of the different microbial assemblies (bacteria, viruses, rickettsiae, fungi, etc.).

April 1974 494 pages £14.06

PRINCIPLES OF DRUG ACTION: The Basis of Pharmacology, Second Edition

By **Avram Goldstein, Lewis Aronow** and **Sumner M. Kalman,** *all of Stanford University School of Medicine.*

Explains principles that govern drug action, absorption, metabolism, distribution and toxicity. Discusses clinical use of drugs and evaluation of drug effects and safety. Uses appropriate drugs to illustrate principles. New in this edition: receptor isolation, the revolutionary advances in analytical chemistry applied to the detection and quantitation of drugs and drug metabolites, environmental toxicity, the immunochemical basis of drug allergies and drug-drug interactions in man.

May 1974 870 pages £11.40

INTENSIVE CARE

By **Ake Wahlin, Lars Westermark** and **Ansje van der Vliet,** *Central Anaesthesiological Dept, Karolinska Sjukhuset, Stockholm.*

Written with the non-specialist in mind, this book explains the routines in intensive care which have been developed in Scandinavia. Its object is to introduce and guide students in all aspects of medical care to the proper planning and running of an intensive care unit. Its practicability is assured since it is based largely on experience gained by the authors in the intensive care unit of the Central Anaesthesiological Department of the Karolinska Hospital, Stockholm, Sweden. This English edition is based on the third Swedish edition of the book.

April 1974 324 pages £6.75

THE MAMMALIAN MYOCARDIUM

Edited by **Glenn A. Langer,** and **Allan J. Brady,** *University of California, Los Angeles.*

A comprehensive analysis of mammalian cardiac function with particular focus on cellular and subcellular function. Synthesizes and summarizes information from a variety of related disciplines.

March 1974 320 pages £13.75

CHEMISTRY OF THE QUINONOID COMPOUNDS

Edited by **Saul Patai,** *The Hebrew University, Jerusalem.*

The series "The Chemistry of the Functional Groups" is planned to cover in each volume all aspects of the chemistry of one of the important functional groups in organic chemistry, in this case the compounds containing quinonoid group. The emphasis is laid on the functional group treated and on the effects which it exerts on the chemical and physical properties, primarily in the immediate vicinity of the group in question, and secondly on the behaviour of the whole molecule. The authors concentrate on important developments and on material which has not been well covered in other literature. (Bound in two parts).

April 1974 1,302 pages £26.00

INTERNAL ROTATION IN MOLECULES

Edited by **W. J. Orville-Thomas,** *Professor of Physical Chemistry, University of Salford.*

This book describes modern developments in the use of physical and theoretical techniques to study problems in conformational analysis. Since Barton's classic paper in 1950, molecular conformational studies have developed into one of the most important fields in chemistry. Nowadays, however, physical methods based on spectroscopic, diffraction and chemical relaxation techniques have largely superseded the chemical methods of the organic pioneers. This change in emphasis is reflected in this work, in which there are contributions describing all the major approaches to studies of potential barriers to rotation in conformational analysis.

April 1974 624 pages £13.50

REACTIVE INTERMEDIATES IN ORGANIC CHEMISTRY

By **N. S. Isaacs,** *University of Reading.*

This book represents a major departure in the organization of organic chemistry texts in that it brings together reactions which occur via a common type of intermediate rather than to classify reactions on the basis of the nature of the product.

April 1974 564 pages £12.00

OPIATE ADDICTION: Origins and Treatment

Edited by **Seymour Fisher,** *Boston University School of Medicine,* and **A. M. Freeman,** *New York Medical College.*

Proceedings of the 1972 meeting of the American College of Neuropsychopharmacology. Topics include the dynamics of drug dependance, social and political influences on addiction research, behavioural analysis of opiate dependance and evaluations of various drug treatment programmes.

April 1974 264 pages £6.35

Published by V. H. Winston and Sons Inc. and distributed by John Wiley and Sons Ltd.

MEDICAL MICROBIOLOGY: Quality Cost and Clinical Relevance

by **Raymond C. Bartlett, M.D.,** *Hartford Hospital, Connecticut.*

Provides guidance in laboratory administration and sets forth principles developed and tested in the clinical microbiology laboratory of a large U.S. community hospital (*Wiley Series on Quality Control Methods in the Chemical Laboratory*).

April 1974 272 pages £8.25

JOHN WILEY & SONS

NEW YORK CHICHESTER SYDNEY TORONTO

John Wiley & Sons Ltd Baffins Lane Chichester Sussex PO19 1UD England

Oxford Books for Students

Oxford Physics Series

General Editors: E. J. Burge, D. J. E. Ingram, J. A. D. Matthew

The aim of this series is to provide a coherent set of short textbooks that together will cover, in a flexible way, all the material required for a degree course in pure physics, or physics combined with other subjects. The series will range from core texts, dealing with material common to all physics courses, through to advanced topics taught as options within courses. Progress from one book to another will present the minimum of difficulty, since the series as a whole will be closely integrated and the books will all have common nomenclature and units.

1. Electromagnetism

F. N. H. Robinson

A clear, brief account of the foundations of electromagnetism – summarized in Maxwell's equations – precedes a thorough discussion of the applications of electromagnetic laws in conducting media, fields due to dipoles, dielectric and magnetic media, electromagnetic waves, and radiation. The book should prepare students for the study of more advanced or specialized texts and enable them to follow the use of electromagnetic theory in other branches of physics, engineering, and chemistry. £2·90 paper covers £1·45

2. D.C. and A.C. Circuits

G. Lancaster

Students leaving school and going on to further study in physical science are confronted in the laboratory with an array of electronic equipment much more sophisticated than any they will have met before. The aim of this book is to ease the confrontation by explaining how these 'black boxes' work. With the advent of widely available, cheap, integrated-circuit devices, an understanding of their functioning is essential. £2·90 paper covers £1·45

3. Radiation and Quantum Physics

D. J. E. Ingram

Integration of pre-university physics with the first-year course, and integration of the various aspects of radiation in all its different forms, are the two main themes of this book. The author develops quantum and other concepts into a coherent pattern of knowledge which includes such topics as the radiation laws and Planck's postulate; energy-distribution and the ideas of statistical mechanics; the photoelectric and Compton effects; Bohr's theory and its limitations; and the wave-particle aspect of matter and energy, linked with the Uncertainty Principle and an introduction to the basic methods of wave mechanics. £2·90 paper covers £1·45

An Introduction to the Study of Man

J. Z. Young

This 'superb introduction to human biology' (*The Lancet*) traces the sources of human activity from their biochemical basis to the highest levels of consciousness. 'Over this remarkable range the information is admirably organized and lucidly and vividly presented . . . . In its combination of biological erudition, concern for profound issues, scientific and social, sensitivity to the problems of mankind and not least to values and aspirations, this is a work of rare distinction' (*Nature*). £6 *Oxford Paperbacks* £1·95

Nucleus and Cytoplasm

Henry Harris

The second edition of this book still aims to provide an introduction to the most important problems in the field of nucleo-cytoplasmic relationships, although the text has been extensively revised to take account of important experimental advances. The recent development of assays for the biological activity of cellular messenger ribonucleic acids, the analysis of transcriptional and translational controls in molecular terms, and the continuing progress in the field of cell fusion have, however, done much to clarify problems that appeared intractable a few years ago. £4·20 paper covers £1·90

The Control of Gene Expression in Animal Development

J. B. Gurdon

This book outlines what is known of the control of gene expression during the earliest stages of animal development and cell differentiation. Each main chapter summarizes the background to its subject and then discusses in detail some of the current research in the area. Special emphasis is given to the experimental analysis of gene regulation in living cells by such techniques as nuclear transplantation and microinjection. £3·50 paper covers £1·25

An Introduction to Applied Mathematics

J. C. Jaeger and A. M. Starfield

This undergraduate textbook is concerned with applying mathematics to physical and engineering problems. The new edition reflects the fact that numerical methods are now as much a part of applied mathematics as the formal theory of ordinary and partial differential equations. Second edition £8·50 paper covers £3·85

Inspection copies of these books are available to lecturers wishing to consider them for adoption as required texts. Please write to **Oxford University Press** (UPS), Ely House, 37 Dover Street, London W1X 4AH

announcements

International meetings

June 2–6, **Radiation Protection: Philosophy and Implementation** (Symposium Organiser, Room 1324, CEGB, Sudbury House, 15, Newgate Street, London EC1A 7AU)

June 3–5, **A festive International Exposition for the Minicomputer Industry** (MINIFEST 74 Secretary, Polytechnic of Central London, 115, New Cavendish Street, London W1M 8JS)

June 3–5, **Applications of Marine Geodesy** (G. W. Lennon, Institute of Coastal Oceanography and Tides, Bidston Observatory, Birkenhead, Cheshire, L43 7RA, UK)

June 3–6, **25th Annual Meeting of the Tissue Culture Association** (Dr Vincent J. Cristofalo, Chairman, TCA Publicity Committee, The Wistar Institute, 36th Street at Spruce, Philadelphia, Pennsylvania 19174)

June 3–7, **International Symposium on N_2 Fixation** (Dr William E. Newton, Charles F. Kettering Research Laboratory, 150, East South College Street, Yellow Springs, Ohio 45387)

June 4, **Using Minicomputers and Programmable Calculators for Stress Analysis and Design** (The Meetings Officer, The Institute of Physics, 47, Belgrave Square, London SW1X 8QX)

June 4–7, **Minerals and the Environment** (Institute of Mining and Metallurgy, 44, Portland Place, London W1N 4BR)

June 6–7, **7th Geodesy/Solid-Earth and Ocean Physics** (GEOP) Research Conference (American Geophysical Union, 1707, L Street N.W., Washington DC 20036)

June 7, **Symposium on Mathematical Economics** (Secretary and Registrar, The Institute of Mathematics and its Applications, Maitland House, Warrior Square, Southend-on-Sea, Essex SS1 2JY, UK)

June 10–13, **8th Annual Conference on Trace Substances in Environmental Health** (Dr Delbert Hemphill, 426, Clark Hall, University of Missouri, Columbia, Missouri 65201)

June 10–14, **Haploids in Higher Plants: Advances and Potential** (University of Guelph, Ontario, Canada)

June 11, **Symposium on Mathematics in Educational Planning** (The Secretary and Registrar, The Institute of Mathematics and its Applications, Maitland House, Warrior Square, Southend-on-Sea, Essex SS1 2JY, UK)

June 11–14, **The Electrodynamics of Substorms and Magnetic Storms** (R. A. Hoffman (Chairman), NASA, Code 646, GSFC, Greenbelt, Maryland 20771)

June 11–14, **8th International Congress for Noise Abatement** (Secretariat Pro Aqua-Pro Vita, ACIB, P.O. Box, CH-4021 Basle, Switzerland)

June 12, **Changing your Computer** (Registration Secretary, BIS-Brandon Training, 80, Blackfriars Road, London SE1 8HB)

June 12, **Glass: An Engineering Material** (The Meetings Secretary, Institution of Metallurgists, Northway House, Whetstone, London N20 9LW)

June 12–14, **International Conference on Submillimeter Waves and their Applications** (K. J. Button, MIT National Magnet Laboratory, Cambridge, Massachusetts 02139)

June 12–15, **Analysis of Lipids and Lipoproteins** (1974 AOCS Lipids Conference, American Oil Chemists' Society, 508, South Sixth Street, Champaign, Illinois 61820)

June 14–22, **17th International Seed Testing Congress** (ISTA Secretariat, Box 68, N 1432 AS-NLH Norway)

June 16–20, **11th Informal Conference on Photochemistry Honoring Professor Francis E. Blacet** (T. W. Martin, Conference Chairman, Box 1506/B, Vanderbilt University, Nashville, Tennessee 37235)

June 17–19, **Velikovsky and the Recent History of the Solar System** (Stephen L. Talbott, Editor *Pensee* Magazine, P.O. Box 414, Portland, Oregon 97207)

June 17–21, **5th International Liquid Crystal Conference** (Conference Secretariat, c/o Stockholm Convention Bureau, Strandvagen 7c, S 114 56 Stockholm, Sweden)

June 19, **26th Annual CIBA Foundation Lecture** (Personal Assistant to the Director, The Ciba Foundation, 41, Portland Place, London W1N 4BN)

June 21–26, **3rd International Congress of Plant Tissue and Cell Culture** (The Secretariat, IAPTC Congress, Botanical Laboratories, University of Leicester, Leicester, LE1 7RH, UK)

June 22–27, **Congress Tertius Societatis Radiologicae Europaeae** (The British Institute of Radiology, 32 Welbeck Street, London W1M 7PG)

June 23–26, **1st International Meeting of the Society "Environment and Health"** (The Secretariat, The National Research Foundation, 48, Vassileos Constantinou Avenue, Athens 501/1, Greece)

June 23–30, **Workshop on Medical Ethics** (Robert M. Veatch, Associate for Medical Ethics, Institute of Society, Ethics and the Life Sciences, 623, Warburton Avenue, Hastings-on-Hudson, New York 10706)

June 24–26, **2nd International Symposium on Mass Spectrometry in Biochemistry and Medicine** (Secretariat c/o Instituto di Ricerche Farmacologiche "Mario Negri" 20157 Milan, Via Eritea, 62, Italy)

June 24–29, **Paris 1974 Immuno-Oncology Week** (Secretariat of the Institut de Cancerologie et D'Immunogenetique, 14, Avenue Paul-Vaillant-Couturier 94800 Villejuif, France)

June 24–28, **Recent Advances in the Assessment of the Health Effects of Environmental Pollution** (The Secretariat, Health Protection Directorate, 29, Rue Aldringen Luxembourg (Grand Duchy))

June 24–28, **Enzymes and their uses in Analysis and Clinical Diagnosis** (Director of the Summer Session, Room E19-356, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139)

June 24–28, **2nd International Symposium on Sex Education** (The Organising Committee, Second International Symposium on Sex Education, P.O.B. 16271, Tel Aviv, Israel)

June 24–28, **9th International Symposium on the Chemistry of Natural Products** (Executive Secretary, 9th International Symposium on the Chemistry of Natural Products, c/o National Research Council of Canada, Ottawa, Ontario K1A 0R6, Canada)

June 25–July 6, **10th International Symposium on Mathematical Geophysics** (Dr J. A. Hudson, Department of Applied Mathematics and Theoretical Physics, Silver Street, Cambridge, UK)

June 27–29, **Gene Regulation in Mammals** (Dr Andrew A. Kandutsch, The Jackson Laboratory, Bar Harbour, Maine 04609)

July 1, **Automated Sequencing for Peptides and Proteins** (Chairman, J. I. Harris, MRC Cambridge, UK)

July 1–3, **549th Biochemical Society Meeting** (The Meetings Officer, The Biochemical Society, 7 Warwick Court, Holborn, London WC1R 5DP)

July 1–5, **6th Symposium on Organic Sulphur Chemistry** (The Secretariat, School of Physical and Molecular Sciences, University College of North Wales, Bangor, LL57 2UW, UK)

July 1–6, **Land use and Society** (The Secretary, S_2A_3 Congress, c/o Rhodes University, Grahamstown, South Africa)

July, 2–4, **The Emergence of Science in Western Europe in Different National Contexts** (The British Society for the History of Science, 47 Belgrave Square, London SW1X 8QX)

July 7–12, **9th International Congress of Neuropsychopharmacology** (Professor J. R. Boissier, General Secretary, Organising Committee, Unite de Neuropsychopharmacology, 2 Rue d'Alesia, 75014 Paris, France)

July 8–10, **Recent Advances in NMR Spectroscopy** (Miss J. M. Usher, The Chemical Society, Burlington House, London W1V 0BN)

July 8–11, **2nd International Conference on the Biology and Pharmacology of Cyclic AMP** (Dr G. I. Drummond, Department of Pharmacology, Faculty of Medicine, University of British Columbia, Vancouver 8, Canada)

July 8–12, **International Dynamic Mass Spectrometer Symposium** (Dr D. Price, Department of Chemistry and Applied Chemistry, University of Salford, Salford M5 4WT, Lancashire, UK)

July 8–12, **Micro 74** (The Administrator, Royal Microscopical Society, Clarendon House, Cornmarket Street, Oxford OX1 3HA, UK)

July 9–12, **Kinetics of Chemical Reactions in Heterogeneous Systems** (Dr Troyanowsky, Secretaire general, Societe de Chimie physique, 10 rue Vauquelin, 75231 Paris Cedex 05, France)

July 9–12, **Interrelation of Structure, Properties and Applications of Polymers** (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1X 8QX)

July 10–12, **Environmental Pollution: Mutation and Selection** (Professor M. A. Ferguson-Smith, Institute of Genetics, Church Street, Glasgow G11 5JS, UK)

July 11–12, **Recent Advances in Vibrational Spectroscopy** (Miss J. M. Usher, The Chemical Society, Burlington House, London W1V 0BN)

July 11–12, **Trace Elements and Nutrition** (Dr J. D. Sutton, Hon. Programmes Secretary, Nutrition Society, National Institute for Research in Dairying, Shinfield, Reading RG2 9AT, UK)

July 12–16, **8th International Congress on Animal Reproduction and Artificial Insemination** (Professor Stefan Wierzbowski, 32-083 BALICE/Krakow, Poland, Institute of Zootechnics, Department of Animal Reproduction and AI)

July 14–20, **5th International Congress of Radiation Research** (Dr W. K. Sinclair, Secretary-General, Argonne National Laboratory, Argonne, Illinois 60439, USA)

July 15, **Workshop Course on Gradient Centrifugation** (Dr E. Reid, Wolfson Bioanalytical Centre, University of Surrey, Guildford GU2 5XH, UK)

July 15–19, **Dynamic Studies with Radioisotopes in Clinical** Medicine **and Research** (International Atomic Energy Agency, Karntner Ring 11-13, P.O. Box 590, A-1011 Vienna, Austria)

July 15–19, **Course in Modern Microscopy** (The Administrator, Royal Microscopical Society, Clarendon House, Cornmarket Street, Oxford OX1 3HA, UK)

July 15–19, **Centenary Celebrations of the Society for Analytical Chemistry** (The Secretary, Society for Analytical Chemistry, 9/10 Savile Row, London W1X 1AF)

July 16–19, **John Innes Symposium: Modifications of the Information contents of Plant Cells** (Miss Justine Speed, Symposium Secretary, John Innes Institute, Norwich NOR 70F, UK)

July 17, **Society for Drug Research, Anti-Obesity Drugs** (Dr J. R. Cavalla, c/o John Wyeth and Brother Ltd., Huntercombe Lane South, Taplow, Maidenhead, Berkshire, UK)

July 21–26, **3rd International Congress of Plant Tissue and Cell Culture** (Secretariat, Third International Congress of Plant Tissue and Cell Culture, Botanical Laboratories, University of Leicester, Leicester LE1 7RH, UK)

July 21–27, **The Applications of Heterogeneous Catalysis** (Centre for Extension Studies, University of Technology, Loughborough, Leics., LE11 3TU, UK)

July 22–26, **Enzyme and Fermentation Biotechnology Course** (The Assistant Secretary, The Society of Chemical Industry, 14 Belgrave Square, London SW1)

July 22–26, **Course in Photomicrography** (The Administrator, Royal Microscopical Society, Clarendon House, Cornmarket Street, Oxford OX1 3HA, UK)

July 22–26, **International Conference on Urban Development Models** (Mrs M. Houston, Land Use and Built Form Studies, University of Cambridge, 16 Brooklands Avenue, Cambridge, UK)

July 22–August 9, **Origin and Abundance of the Chemical Elements** (Professor Martin Rees, Institute of Astronomy, Madingley Road, Cambridge CB3 0HA, UK)

July 23–31, **8th International Congress on Acoustics** (The Administrative Secretary, Eighth International Congress on Acoustics, 47 Belgrave Square, London SW1X 8QX, UK)

July 25–27, **29th Annual Calorimetry Conference** (Harry Watts, Resarch and Development Department, Dow Chemical of Canada, Limited, P.O. Box 1012, Sarnia, Ontario N7T 7K7, Canada)

July 29–August 9, **Energy: A Unified View** (Director of the Summer Session, MIT, Room E19-356, Cambridge, Massachusetts 02139, USA)

August 1–2, **International Symposium on Microwave Acoustics** (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1X 8QX)

August 2–8, **International Committee on Avian Anatomical Nomenclature** (Dr John McLelland, Secretary of ICAAN Department of Anatomy, Royal School of Veterinary Studies, Edinburgh EH9 1QH, Scotland, UK)

Erratum

In the article "Speeding up astronomical photography" (*Nature*, **249**, 22; 1974) by P. M. Corben, V. C. Reddish and M. E. Sim, the letters *a* and *b* on Fig. 2 were unfortunately interchanged during preparation of the illustrations for printing.

APPOINTMENTS VACANT

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF BIOLOGY

Applications are invited from students expecting to graduate in 1974 with 1st or upper 2nd class honours in Plant Physiology or a related subject for an S.R.C. C.A.S.E. studentship to work on factors influencing inflorescence and fruit development in glasshouse-grown tomato plants. The project will be carried out in co-operation with the Glasshouse Crops Research Institute, Rustington. Candidates will be expected to register for a higher degree.

Applications (including a curriculum vitae and the names of two referees) should be addressed as soon as possible to Dr. D. A. Morris, Department of Biology, Building 44, The University, Southampton SO9 5NH, from whom further details may be obtained. (Tel. Southampton 559122, ext. 2032). (1960)

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF ZOOLOGY

The University invites applications for the post of DEMONSTRATOR in the Department of Zoology. The appointment will be for a period of three years, subject to annual renewal, and will be tenable from September 1, 1974. Preference will be given to candidates experienced in comparative physiology. Applicants should possess a higher degree or equivalent postgraduate research experience.

Salary will be at an appropriate point on the scale £1,929 to £2,223 (from October 1974 £2,118 to £2,412) according to age, qualifications and experience. Membership of F.S.S.U. required.

Further particulars may be obtained from the Registrar, The University, Newcastle upon Tyne NE1 7RU with whom applications (3 copies), together with the names and addresses of three referees, should be lodged not later than June 8, 1974. Please quote reference N. (1965)

UNIVERSITY OF SURREY
DEPARTMENT OF METALLURGY AND MATERIALS TECHNOLOGY

LECTURER IN MATERIALS TECHNOLOGY

Applications are now invited for the post of Lecturer in Materials Technology within the Department of Metallurgy and Materials Technology.

Preference will be given to younger applicants with a substantial chemistry background since there is a need to strengthen the teaching of chemistry of materials, in particular, plastics, in the context of materials technology. The successful applicant will also have a keen interest in research, preferably in the field of composite materials or fibre science. There is a strong research group in these fields within the Department and it is hoped that the successful applicant would strengthen this group by undertaking the supervision of research work and generating new research projects.

The appointment will be made initially at £2,718 per annum from October 1, 1974 for one year, and thereafter on the Lecturer scale.

Further particulars may be obtained from the Academic Registrar (LFG), University of Surrey, Guildford GU2 5XH. Tel. Guildford 71281, extension 452. Applications, in the form of a curriculum vitae, including present salary and the names and addresses of two referees, should be sent to the same address not later than June 14, 1974. (1964)

Department of Employment
Employment Medical Advisory Service
Central Reference Laboratory, Bayswater

Biochemist/Chemist

■ **Varied and unusual work, mainly concerned with examination of biological samples taken from industrial workers** ■ **Opportunities for development and applied research work in trace metal analysis field.**

□ Degree, HNC or equivalent in Biochemistry, Chemistry □ Final year students may apply □ Experience in atomic absorption spectrophotometry, gas chromatography or pology an advantage □ Should preferably have worked in hospital biochemical or similar laboratory □ Age under 27 □ Appointment as Scientific Officer (£1663-£2557 under review) □ Ref: SB/7/DB.

□ Application forms (for return by 18 June 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Ministry of Agriculture, Fisheries and Food
Royal Botanic Gardens, Kew

Botanist

■ **In Herbarium grasses section** ■ **Revise critical genera or groups of species** ■ **Conduct research on overall classification of grass family, including investigation of new techniques** ■ **Assist curatorial supervision of Herbarium collection.**

□ 1st/2nd hons degree in Botany □ Final year undergraduates may apply □ Age under 27 □ Appointment as Scientific Officer (£1525-£2419 under review) □ Ref: SB/9/AH.

□ Application forms (for return by 17 June 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Department of Employment
HM Factory Inspectorate, Cricklewood

Chemist

■ **Testing of chemical dusts and inflammable liquids** ■ **Providing technical and scientific support for accident and explosion investigations** ■ **Frequent travel.**

□ Degree, HNC or equivalent in relevant subject □ Final year students may apply □ Experience in metallurgy, chemical analysis or development of pilot scale testing methods using instrumental techniques desirable □ Knowledge of mechanical/electrical engineering an advantage □ Ability to drive □ Age under 27 □ Appointment as Scientific Officer (£1545-£2439 under review) □ Ref: SB/6/DB.

□ Application forms (for return by 18 June 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Chemists

■ **Sampling and analysis of various toxic materials in factories** ■ **Limited amount of travel assisting Chemical Inspection on visits to factories** ■ **Development of new analytical methods may also be involved.**

□ Degree, HNC in appropriate subject □ Final year students may apply □ Knowledge of microscopy, X-ray diffraction and florescence, gas chromatography, mass spectropgraphy, atomic absorption and emission spectroscopy advantageous □ Ability to drive □ Age under 27 □ Appointment as Scientific Officer (£1545-£2439 under review) □ Ref: SB/5/DB.

□ Application forms (for return by 17 June 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Science group
CIVIL SERVICE

(2006)

Scottish Health Service

COMMON SERVICES AGENCY

SCOTTISH BLOOD TRANSFUSION CENTRE

Applications are invited for the post of **PRINCIPAL SCIENTIFIC OFFICER** in the above Department. The successful applicant will be responsible to the Regional Director for the day to day management of the scientific, logistic and technical aspects of the Blood Bank and Blood Component Divisions in which 35 technical and scientific staff are employed.

The post is on the Principal Biochemist salary scale, and NHS terms and conditions of service will apply. Further particulars may be obtained from the National Administrator, Scottish Blood Transfusion Service, 17 Rothesay Terrace, Edinburgh EH3 7SF. Applications with the names of 2 referees should be forwarded to the Secretary, Common Services Agency for the Scottish Health Service, 17/18 Rothesay Terrace, Edinburgh EH3 7SF not later than 8th June, 1974.

(1935)

Antarctic Expedition

OBSERVATORY AND IONOSPHERIC PHYSICISTS, ELECTRONIC TECHNICIANS AND ELECTRONIC ENGINEERS

Qualifications: According to post from Honours Degree to O.N.C. or appropriate Armed Service training.

Thorough training is given in all cases and the tour of duty covers two Antarctic winters involving an absence from the United Kingdom of about 30 months. Some categories will be required to work on their field data for up to a year after their return from Antarctica.

Free messing, clothing and canteen. Low income tax.

Applicants must be single and 22 - 30.

If you are interested in seeing a largely unknown, remote and fascinating part of the world please write to:

The Establishment Officer,
British Antarctic Survey,
30, Gillingham Street,
LONDON, SW1V 1HY
Tel: (01) 834 3687

NATURAL ENVIRONMENT RESEARCH COUNCIL

(2035)

UNIVERSITY OF DURHAM

DEPARTMENT OF BOTANY

A POSTDOCTORAL RESEARCH ASSISTANTSHIP is available for three years, to start as early as possible, to work in collaboration with Professor Boulter, on the biochemistry of protein synthesis in peas and beans. Chemists, biochemists and botanists may apply.

Salary will be at an appropriate point on the scale £1,866 to £2,586 per annum (under review), with F.S.S.U.

Applications (3 copies) naming three referees, should be sent by May 27, 1974 to the Registrar and Secretary, Science Laboratories, South Road, Durham, DH1 3LE, from whom further particulars may be obtained. (1963)

THE UNIVERSITY OF NEWCASTLE UPON TYNE CHAIR OF BACTERIOLOGY

Applications are invited for the post of Professor of Bacteriology which will become vacant on October 1, 1974, following the retirement under the age limit of the present holder, Professor C. A. Green. The post carries with it, initially, the Headship of the Department of Microbiology. It is not a condition of appointment that the candidate should hold a registrable medical qualification. Salary in accordance with the appropriate Professorial Scale (Clinical or Non-Clinical), with membership of F.S.S.U.

Further particulars may be obtained from the Registrar of the University, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU, with whom applications (15 copies), giving the names of not more than three referees, must be lodged not later than June 8, 1974. (Applicants from outside the British Isles may submit one copy only). (1966)

UNIVERSITY OF NOTTINGHAM SCHOOL OF AGRICULTURE

Sutton Bonington, Loughborough

Applications are invited from students expecting to gain a good Honours degree in either Nutrition, Physiology or Biochemistry for an M.R.C. studentship in the Department of Applied Biochemistry and Nutrition to work with Dr R. J. Neale, Lecturer in Human Nutrition. Research interests are those of amino acid metabolism in undernutrition, iron availability from plant proteins and intestinal transport and metabolism.

Applications in writing to be received by June 10, 1974. (1969)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

A postdoctoral research assistant is required for a project financed by the Wellcome Trust for work with Dr. R. J. Mayer on "Studies on the turnover of monoamine oxidase with implications for migraine". Experience in membrane enzymology and immunochemical techniques would be extremely valuable for the work. The appointment is for three years beginning on October 1, 1974, starting salary from £2,118 to £2,412 depending on age and experience.

Applications, including curriculum vitae and names of two referees should be sent to Dr R. J. Mayer, Department of Biochemistry, The Medical School, University of Nottingham, Nottingham NG7 2RD. (1971)

JUNIOR TECHNICAL OFFICER

required in the laboratories of the INSTITUTE OF CANCER RESEARCH, Sutton, Surrey. The successful candidate will work in a department concerned with the biochemical pharmacology of anti-tumour agents, and should possess either 'A' levels in science subjects (chemistry and biology), H.N.C. (pharmacology and/or biochemistry), or equivalent qualifications. Salary in the range £1,299 to £2,199, according to age, qualifications and experience. Apply in duplicate with the names of 2 referees to the Secretary, 34 Sumner Place, London, S.W.7, quoting ref. 301/B/517. (1972)

JUNIOR TECHNICAL OFFICER

required by INSTITUTE OF CANCER RESEARCH, Fulham Road, S.W.3, to assist with the work in the Division of Molecular Biology. Experience in the field of protein chemistry would be an advantage as initially the successful candidate would be engaged in amino acid analyses. Candidates should have at least 2 G.C.E. 'A' level passes in Chemistry, Physics or Mathematics. Starting salary according to qualifications and experience approx. £1,300 to £1,550 in scale extending to £2,200. Apply in duplicate to the Secretary, 34 Sumner Place, S.W.7, with the names of two referees and quoting ref. 301/B/515. (1973)

UNIVERSITY OF EDINBURGH

DEPARTMENT OF VETERINARY

ANATOMY

RESEARCH ASSISTANTSHIP

The Agricultural Research Council has awarded a research assistantship to the Department of Veterinary Anatomy for a project concerned with the mechanism of motility in mammalian spermatozoa. The work will depend principally on advanced methods in electron microscopy, for which training will be given.

Applications are invited from students who have, or expect soon to have, a good Honours degree in Zoology or an associated discipline. The salary of the assistant will be at a level approximately equivalent to the value of an S.R.C. postgraduate studentship. The appointment will be for three years, commencing October 1, 1974, and the successful applicant will be expected to register for the degree of Ph.D. (for which the fees will be paid).

Applications, together with the names of two referees, should be sent as soon as possible to Dr D. M. Woolley, Department of Veterinary Anatomy, Royal (Dick) School of Veterinary Studies, University of Edinburgh, Edinburgh EH9 1QH. Please quote reference number 5018. (1979)

JUNIOR TECHNICAL OFFICER

required in BIOPHYSICS DEPARTMENT OF INSTITUTE OF CANCER RESEARCH, Sutton, Surrey, for work concerned with the action of chemotherapeutic agents on normal and tumour tissues. The work involves various cell transplantation and counting techniques. Applicants should preferably have a degree or equivalent in a biological subject or alternatively considerable experience in relevant experimental work. Good canteen and social facilities. Salary according to M.R.C. scales in the range £1,300 to £2,200. Apply in duplicate with names of two referees to the Secretary, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/516. (1974)

UNIVERSITY OF HULL

DEPARTMENT OF EDUCATIONAL STUDIES

Applications are invited for appointment as Research Officer or Research Assistant to work under the direction of Dr H. B. Miles in an investigation of factors associated with 'A' level performance. Familiarity with methods of multivariate analysis and computer use necessary; research experience in education desirable. The post may interest someone with qualifications in Statistics, Mathematical Statistics or Operational Research.

Salary on the scale: £2,883 to £3,378 (Research Officer), or £1,518 to £2,223 (Research Assistant), with placing according to qualifications and experience. Plus F.S.S.U. benefits.

Applications (6 copies) giving details of age, qualifications and experience together with the names of three referees should be sent by May 31, 1974, to the undersigned from whom further particulars may be obtained. F. T. Mattison, Registrar. (1975)

UNIVERSITY OF EDINBURGH

DEPARTMENTMENT OF VETERINARY

ANATOMY

RESEARCH ASSISTANTSHIP

DEPARTMENT OF VETERINARY

awarded a three-year research assistantship, commencing October 1, 1974, to the Department of Veterinary Anatomy for a project investigating the sensory mechanisms in the avian respiratory tract and involving the use of techniques in electron microscopy and cytochemistry. Applications are invited from students who have, or expect to obtain shortly, a good Honours degree in Zoology, Physiology or Biochemistry. The salary of the assistant will be at a level approximately equivalent to the value of an S.R.C. Postgraduate studentship. The successful applicant will be expected to register for the degree of Ph.D.

Applications, consisting of a brief curriculum vitae and the names of two referees, should be sent to Dr J. McLelland, Department of Anatomy, Royal (Dick) School of Veterinary Studies, University of Edinburgh, Edinburgh EH9 1QH, as soon as possible. Please quote reference number 5019. (1980)

Scientist for Drug Metabolism Studies

We have a vacancy in the Drug Metabolism section of our Biochemistry Department for a scientist to participate in a varied programme of work on the metabolism and pharmacokinetics of new and established drugs. Applications are invited from candidates with a good honours degree in chemistry, biochemistry or pharmacy and several years post-graduate experience leading to a higher degree, in a relevant field of research.

This is an excellent opportunity for someone wishing to pursue a career in this important specialised area of applied research, to join an experienced and enthusiastic group of scientists working in new well-equipped laboratories. While postgraduate and postdoctoral experience in drug metabolism work would be an advantage, we would consider applications from those with experience of bioanalytical techniques, separation methods and isotopic tracer work who believe that their experience could be applied usefully to the study of drug metabolism.

Roche Products Limited is part of one of the world's largest and most successful research-based pharmaceutical companies and is itself one of the leaders in the UK. Working conditions and Conditions of Service are excellent. In appropriate cases some substantial assistance with re-location will be available. Please write in confidence quoting reference RB for a personal history form, further information on this post and a Company booklet to the Welwyn Personnel Manager.

ROCHE

Roche Products Limited

(2101)

The Netherlands Cancer Institute
Antoni van Leeuwenhoekhuis, Amsterdam.
Applications are invited for position of a

Senior Research Geneticist

preferably with experience in immunogenetics for research on histocompatibility with relation to cancer in animals. •

Request for further information and applications can be addressed to: •

Prof. O. Mühlbock,
Biology Department,
Sarphatistraat 108,
Amsterdam-Holland.

(2071)

Natural Environment Research Council
Higher Scientific Officer/Senior Scientific Officer Vacancies
University Support Division

The Council provides selective support for research and postgraduate training in the natural environmental sciences. The duties of the University Support Division include the assistance of Council in the formulation of its policies for university support and the implementation of these policies.

Two Higher Scientific Officers/Senior Scientific Officers are required in the Division at the Council's Headquarters in London, which are due to move to Swindon within the next few years.

DUTIES:

The successful applicants will be expected to assist in all the activities of the Division; they will each have special responsibility as Secretary of one of the Council's grants committees covering the field of the Aquatic Life Sciences and Terrestrial Life Sciences respectively. Duties will include the servicing of these Committees with the assistance of executive and clerical staff and maintaining liaison with research workers at universities and other research institutes.

QUALIFICATIONS:

An appropriate first or second class honours degree (or equivalent) and at least two years relevant post-graduate experience, preferably in research or administration in the life sciences.

SALARY SCALES

HSO £2,396–£3,029

SSO £2,973–£4,070

Starting salaries may be above the minimum.

Non-contributory superannuation arrangements. Paid annual leave of 4 weeks and 2 days, plus public and privilege holidays.

Application forms may be obtained from Establishments Division, NERC Headquarters, Alhambra House, 27/33 Charing Cross Road, London WC2H 0AX. (Quoting reference E2/G2/105 and stating for which post you are applying). Closing date: 14th June, 1974.

(1977)

PAISLEY COLLEGE

Applications are invited for three posts as LECTURER (Grade I or II) in the DEPARTMENT OF BIOLOGY.

i. **LECTURER IN BIOLOGY.** Preference may be given to a candidate with experience in the area of cell biology and genetics.

ii. **LECTURER IN PLANT ECOLOGY.** Preference may be given to a candidate with interests in algology. The person appointed will also be expected to assist with the teaching of plant physiology.

iii. **LECTURER IN ENVIRONMENTAL BIOLOGY.** Preference may be given to a candidate with experience of applied ecology in relation, for example, to natural resource management, or to animal behaviour in the field.

Candidates should have a good Honours degree and either a second degree or other research experience. Teaching experience is also desirable. The successful candidates will be asked to share in the teaching of M.I.Biol., BSc. degree and HND students. They will be encouraged to develop research in their own fields.

Salary scales: Grade I — £1,905–£4,173
II — £1,773–£3,750

Application forms and further particulars from Establishment Section, Paisley College of Technology, High Street, Paisley PA1 2BE (Tel. 041-887 1241) quoting ref. N/11/1 (indicating post i, ii, or iii). Closing date 12th June, 1974.

(1986)

JUNIOR TECHNICAL OFFICER

MEDICAL RESEARCH COUNCIL
GASTROENTEROLOGY UNIT

Research assistant needed to work on projects involving immunological and biochemical technique. Interesting work, contact with patients. Experience of immunology desirable, but not essential. Qualifications: B.Sc. or H.N.C. Salary in the range of £1,173 to £2,073 plus £126 London Weighting. Please apply, with curriculum vitae, to The Director, M.R.C. Gastroenterology Unit, Central Middlesex Hospital, Park Royal, London NW10 7NS.

(1981)

SEALE-HAYNE COLLEGE

DEPARTMENT OF FOOD TECHNOLOGY

Applications are invited for the newly created position of HEAD OF DEPARTMENT. The successful candidate will have the opportunity to develop the Higher National Diploma courses in General Food Technology and Food Technology with a Dairying Specialisation, both courses are mounted jointly with the Bristol Polytechnic. The post will be at the Head of Department Grade II level and within the present salary range of £3,345 to £2,753 per annum (under review). Further details may be obtained from The Principal, Seale-Hayne College, Newton Abbot, Devon TQ12 6NQ, to whom applications should be sent as soon as possible.

(1982)

HEALTH SCIENCES CENTRE

Winnipeg, Manitoba, Canada

Applications are invited from suitably qualified and experienced individuals for the position of

DIRECTOR OF CLINICAL CHEMISTRY

in the largest Teaching Hospital affiliated with the University of Manitoba.

The incumbent will direct the laboratory which supports clinical activities of the medical staff in a wide range of disciplines, co-operates in providing support for education and has an internal research programme, as well as supporting the research of others in the Centre.

Enquiries, accompanied by curriculum vitae, should be directed, in the first instance, to:

The Vice-President (Medical),
Health Sciences Centre,
A143, General Centre,
700 William Avenue,
Winnipeg, Manitoba,
R3E 0Z3.

(1990)

NATURAL ENVIRONMENT RESEARCH COUNCIL

INSTITUTE OF GEOLOGICAL SCIENCES

SCIENTISTS

are required in the Institute's Field Survey, Engineering Geology, Applied Geophysics, Continental Shelf and Mineral Assessment Units. The majority of staff are based on London, others on Leeds, Edinburgh or Belfast. Most staff are expected to undertake field work. Opportunities for service overseas. Appointment will be for a three-year period which may in some cases be extended. There are prospects for a limited number of staff to transfer to permanent posts.

Qualifications: Scientific Officer: Degree, H.N.C. or equivalent; for some posts a 1st or 2nd class honours degree is preferred (Final year students may apply). Age normally under 27. Higher Scientific Officer: Degree, H.N.C. or equivalent (with at least 5 years' postgraduate experience); for some posts a 1st or 2nd class honours degree (with at least 2 years' postgraduate experience) is preferred. Age normally under 30. Senior Scientific Officer: 1st or 2nd class honours degree or equivalent and at least 4 years' relevant postgraduate or other approved experience. Age normally at least 25 and under 32.

Salaries (under review): Scientific Officer £1,435 to £2,329; Higher Scientific Officer £2,221 to £2,854; Senior Scientific Officer £2,798 to £3,895. Starting salaries may be above the minima. Salaries £175 more in London. Promotion prospects.

The staff of the Council are not Civil Servants although their pay and conditions of service are similar to those of Scientists in the Civil Service.

For full details and an application form (to be returned by June 21, 1974), write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222, ext. 500 or London 01-839 1992 (24-hour answering service), quoting S/168/74.

(1985)

SEALE-HAYNE COLLEGE

HEAD OF THE DEPARTMENT OF AGRICULTURE

Applications are invited for the above position which will become vacant on September 1, 1974. The person appointed will be responsible to the Principal for the Higher and Ordinary National Diploma courses in Agriculture. There will be opportunities for research. The appointment will be made in the Head of Department Grade II level and within the salary range of £3,345 to £3,753 per annum (under review). Further details may be obtained from The Principal, Seale-Hayne College, Newton Abbot, Devon TQ12 6NQ, to whom applications should be sent as soon as possible. (1983)

TECHNICIAN

with H.N.C. or equivalent qualification required to work on problems in chemical carcinogenesis mainly using cultured cells. Tissue culture or microbiological experience preferred. Salary on Whitley Council Scales in the range £1,566 to £1,971 p.a. according to age and experience. Applications, together with the names of two referees, to Dr J. P. Roscoe, School of Pathology (N), The Middlesex Hospital Medical School, Riding House Street, London W1P 7LD. (1989)

UNIVERSITY COLLEGE

GALWAY, EIRE

HUMAN CYTOGENETICS UNIT

TECHNICIAN

Applications are invited for the above post of Technician in the Human Cytogenetics Unit in the Microbiology Department, commencing salary within the scale £1665 x 72 - £1,953 (under review).

Qualifications: Technician's Certificate of Department of Education, Science Laboratories Technician's Certificate of City and Guilds, Intermediate examination of the Institute of Medical Laboratory Technology, National Certificate in Medical Laboratory Sciences or equivalent.

Experience of Human Cytogenetics or photography desirable but not essential.

Full details and application form from Secretary, Department of Microbiology, University College, Galway, Eire. (1999)

HARVARD MEDICAL SCHOOL

Applications are invited for two new positions as Assistant Professors in the Department of Microbiology and Molecular Genetics, Harvard Medical School, Boston, Mass. The applicants should have either an M.D. or Ph.D. degree and have demonstrated capacity for independent research in animal cell viruses or aspects of macromolecular control in animal cells. Responsibilities include teaching of graduate and medical students. Write Dr Jon Beckwith, Dept. of Microbiology and Molecular Genetics, Harvard Medical School, 25 Shattuck Street, Boston, Massachusetts 02115 and include a complete curriculum vitae with publications and the names and addresses of three references.

An Equal Opportunity, Affirmative Action Employer. (1991)

CHAIR OF ANATOMY

Medical College and large teaching hospital in major medical center is considering applications for the chair of anatomy. Rush-Presbyterian-St. Luke's Medical Center is an equal opportunity/affirmative action employer. For further information please contact Dr. J. Francis Hartmann, Chairman of the Anatomy Search Committee, Rush-Presbyterian-St. Luke's Medical Center, c/o Department of Neurology, 1753 West Congress Parkway, Chicago, Illinois 60612 U.S.A. (1995)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

A postdoctoral research assistant is required for a project financed by the Wellcome Trust for work with Dr. R. J. Mayer on "studies on the turnover of monoamine oxidase with implications for migraine". Experience in membrane enzymology and immunochemical techniques would be extremely valuable for the work. The appointment is for three years beginning October 1st, 1974, starting salary from £2118 to £2412 depending on age and experience.

Applications, including curriculum vitae and names of two referees should be sent to Dr. R. J. Mayer, Department of Biochemistry, The Medical School, University of Nottingham, Nottingham, NG7 2RD. (1997)

NEW ZEALAND

Department of Scientific and Industrial Research

Scientist

The Cement and Concrete Section of the Chemistry Division, Lower Hutt, has a vacancy for an Analytical Chemist with experience in the analysis of ceramic, cementitious or non-metallic materials and in the application of modern instrumental techniques. Duties would be to develop and apply analytical methods and work with a group conducting investigation into the effects of chemical properties on the physical behaviour of concrete and allied products.

Qualifications: minimum of a good Honours degree.

Salary: up to NZ$8568 p.a. dependent on qualifications and experience.

Further details of the position and passage assistance etc., may be obtained from the

Scientific Liaison Officer,
New Zealand House, Haymarket,
London SW1Y 4TQ.

Applicants should quote Vacancy No. 2/279/2079 and forward applications to the High Commissioner for New Zealand by July 23, 1974 (1996)

Public Service Canada **Fonction publique Canada**

This competition is open to both men and women

Research Statistician

St. John's, Newfoundland

Salary up to $24,262

DUTIES: The Newfoundland Biological Station requires a scientist to undertake research studies in statistical theory and methodology in response to problems arising in fisheries research; act as statistical consultant to scientific and professional staff; direct the operation of a computer terminal; to develop specifications for statistical and mathematical computer programs; to supervise the operation of a data processing unit.

QUALIFICATIONS: Include a Doctorate degree, or a lesser degree with related independent research experience equivalent to that required for a Doctorate degree, with specialisation in an area related to the duties of the position. Knowledge of the English language is essential.

To ensure consideration, please forward "Application for Employment" (Form PSC-367-401) available at Post Offices, Canada Manpower Centres, Public Service Commission of Canada offices, or a detailed resumé before JUNE 28, 1974, quoting reference number 73-100-124-N and send it to:

Sciences and Technology Program,
Public Service Commission of Canada,
Tower "A", Place de Ville,
Ottawa, Ontario. K1A 0M7.

Appointments as a result of this competition are subject to the provisions of the Public Service Employment Act. (2007)

BIOMETRICIAN

Applications are invited for a permanent and pensionable post in the Biometrics Division of the Department of Agriculture, Northern Ireland.

The successful candidate will be concerned mainly with the following:

(1) design and analysis of laboratory and field experiments and surveys;

(2) the statistical assessment of genetical studies on poultry, cattle and herbage plants;

(3) the development and application of computer based systems for handling scientific and other data associated with research and development in Agriculture.

The successful candidate may be required to undertake teaching duties in the Faculty of Agriculture, The Queen's University, Belfast.

Appointment to the post may be at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level, the qualifications for which are:

SSO Over 25 and under 32 years of age with a first or second class Honours Degree or equivalent in mathematics or biology with specialisation in and/or experience of statistics with special reference to the design and analysis of experiments and surveys. Candidates at this level should have at least 4 years relevant post-graduate experience.

HSO Under 30 years of age with an Honours Degree as above and at least 2 years relevant post-graduate experience.

SO Under 27 years of age with an Honours Degree as above.

Grading and commencing salary will be related to qualifications and experience on the following scales:

SSO £2,798-£3,895 HSO £2,221-£2,854 SO £1,435-£2,329

Please write or telephone for an application form, quoting Ref. SB 136/74/N to the Secretary, Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26). Completed forms must be returnd to arrive not later than 30th May, 1974.

(1988)

NORTHERN IRELAND CIVIL SERVICE

Agricultural Research Council
POULTRY RESEARCH CENTRE

Applications are invited for the following posts within the Scientific Officer class in the Nutrition Section of the Poultry Research Centre:-

Post "A" The duties will initially be studies on the value of non-conventional foods for market turkeys and ducks and cost/effectiveness studies on egg production. Candidates should have a good Honours degree (and preferably a Ph.D.) in a biological subject.

Post "B" The duties will initially be to assist with studies to assess the vitamin requirements of poultry and to correlate growth and biochemical criteria with vitamin status. Candidates should have a pass degree, HNC or equivalent in a chemical subject.

Post "C" The duties will initially be to assist with studies on the feeding of broiler and turkey breeders and on the cost/effectiveness of poultry meat production. Candidates should have a pass degree, HNC or equivalent in a biological subject.

Salary: **Post "A"** Higher Scientific Officer £2221 - £2854. Senior Scientific Officer £2798 - £3895. Starting salary according to qualifications and experience. At least 2 years post qualifying experience is required for appointment at HSO, and 4 years for SSO.

Posts "B" & "C" Scientific Officer £1435 - £2329, starting salary according to qualifications and experience.

All posts are superannuable, with a non-pensionable allowance to offset personal contributions.

Application forms, which may be obtained from the Secretary, Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh EH9 3JS, and stating the post for which the application is made, should be completed and returned to him not later than the 31st May 1974.

(1993)

BIOCHEMIST

Required to join group studying male reproduction and fertility control. Previous experience in hormone assays of advantage. Knowledge of German not required. Salary range: DM 2000—3000 per month. Apply to: Dr. E. Nieschlag, 2. Medical Clinic of the University, Moorenstrasse 5, 4 Düsseldorf (Germany). (1994)

THE UNIVERSITY OF MANCHESTER
INSTITUTE OF SCIENCE AND TECHNOLOGY
DEMONSTRATOR IN BIOCHEMISTRY

Applicants with some experience of biological research and a degree or equivalent qualification are invited to apply for the above vacancy in the Department of Biochemistry, which becomes available from 1st October, 1974.

Commencing Salary: £1,764 per annum with F.S.S.U. rising to £1,839 per annum for the second and any subsequent years.

Letters of application stating qualifications and experience, together with the names and addresses of two referees should be forwarded to Professor A. A. Eddy, Department of Biochemistry, U.M.I.S.T., Sackville Street, Manchester M60 1QD. (1998)

UNIVERSITY OF NATAL
Durban
DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited from suitably qualified persons for appointment to the two posts of

1. LECTURER

2. SENIOR LECTURER

Preference will be given to applicants in the field of ecology (preferably marine ecology) and in the field of whole-organism biology. Applications will be considered from persons with predominantly zoological or botanical teaching experience, but an interest in the presentation of integrated biology courses is essential.

The salary scales attached to the posts are:

Lecturer; R4800 x 300 - R6900
Senior Lecturer; R6600 x 300 - R8100
+ 15% pensionable allowance.

The commencing salary will be dependent upon the qualifications and experience of the successful applicants. The senior post may be awarded in either of the required fields. An annual vacation savings bonus up to R260 for married men and R130 for women and single men is payable subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, to whom applications should be submitted by 15th July, 1974, quoting Reference Adv. 67/74. (2000)

BIO-RESEARCH LABORATORIES LTD.
CANADA

Applications are invited from qualified Veterinary Pathologists interested in joining the Department of Toxicology in the capacity of Staff Pathologist. Responsibilities will include technical supervision of Autopsy Room and Histology Laboratory personnel and activities. Principally, however, the successful candidate will be responsible for the evaluation of histological specimen material arising out of toxicological research in a variety of laboratory animal species and for the preparation of reports appropriate to the research in question. Salary will be commensurate with qualifications and experience.

Bio-Research Laboratories Ltd. is a Canadian research company operating in the life sciences field. Applications, curricula vitarum and requests for further details may be directed to Dr. C. I. Chappel, Director, Bio-Research Laboratories Ltd., 265 Hymus Blvd, Pointe Claire, Quebec, Canada H9R 1G6. (1799)

THE UNIVERSITY COLLEGE OF WALES
Aberystwyth
DEMONSTRATOR IN BIOCHEMISTRY

Applications are invited for the post of Demonstrator in the Department of Biochemistry and Agricultural Biochemistry. Applicants should hold an Honours Degree or equivalent qualification in Biochemistry, Chemistry or related disciplines.

Salary: £1,758 to £1,923 p.a. Appointment for one year, renewable up to three years.

Further particulars and application forms can be obtained from the Registrar. Closing date: June 7, 1974. (2015)

JUNIOR TECHNICAL OFFICER

required at Pollards Wood Research Station of INSTITUTE OF CANCER RESEARCH, Chalfont St. Giles, Bucks, to take part in a research programme on mutagenic effects of carcinogens. B.Sc. or H.N.C. in biological subject. Experience in genetics, cytology or cell biology desirable. Starting salary £1,400 p.a. in a scale extending to £2,073, according to qualifications, age and experience. Apply in duplicate with the names of two referees, to the Secretary, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/518. (2017)

ST. BARTHOLOMEW'S HOSPITAL
West Smithfield, London EC1A 7BE

ELECTRONICS ENGINEER

Applications are invited from honours graduates in Electronic Engineering, or Electrical Engineering or Physics for the above research post in the Department of Medical Electronics. The research programme involves the application of electronic techniques to clinical medicine in ultrasonics, transducer design and signal processing. The successful applicant will be expected to be involved in circuit design for the research programme carried out in the Department as well as initiate his own research. Suitable research work may be considered for a higher degree. Previous hospital experience is not essential although industrial experience would be an advantage.

The appointment will be on the scale £1,764 to £4,299.

Applications in writing naming two referees, to the Personnel Office, quoting ref. R/4488/N. (2018)

UNIVERSITY OF LIVERPOOL
Chair of Clinical Pharmacology

Applications are invited for the Chair of Clinical Pharmacology which will become vacant on September 30, 1974, following the retirement of Professor A. Wilson.

The salary of the Professor will be within the range approved for clinical Professorial salaries and initially will depend on the qualifications and experience of the successful candidate.

Applications (16 copies), together with the names of three referees, should be received not later than June 3, 1974 by the undersigned, from whom further particulars may be obtained. (Candidates overseas may send one copy only, by airmail). Quote ref. RV/N/276015.

H. H. Burchnall,
Registrar,
The University,
P.O. Box 147,
Liverpool L69 3BX. (1872)

UNIVERSITY OF OXFORD
DEPARTMENT OF BIOCHEMISTRY

M.R.C. IMMUNOCHEMISTRY UNIT

A vacancy exists for a Junior Technical Officer/Technical Officer in the above unit. Applicants should be qualified to Higher National Certificate standard and have several years' experience in biochemical/analytical techniques, including spectrophotometry, chromatography and radiochemistry. Some knowledge of protein chemistry and an ability to work with small animals is desirable, but not essential.

Salary, according to age and experience, on the scale £1,854 to £2,073 (bar) £2,184 to £3,057 (under review. Applications, including full details of education and career to date, and the names of two referees, to: The Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU. (1891)

UNIVERSITY OF LONDON
King's College

RESEARCH ASSISTANT IN PHARMACOLOGY

Applications are invited from graduates in the biological sciences for the above post in connection with a research project on nicotine dependence. Applicants should have at least two years experience in postgraduate research and preferably have some knowledge of neurotransmitter estimation or radio immunoassay techniques.

The post is for a period of three years. Salary approximately £2,100 rising by yearly increments of £125 plus F.S.S.U. benefits.

Applicants should apply in writing, including a curriculum vitae and names of two academic referees, to Dr. J. M. Littleton, Department of Pharmacology (N), King's College, Strand, London WC2R 2LS. (2022)

Department of Agriculture

Applications are invited for a permanent and pensionable post in the Crop and Animal Husbandry Division, Northern Ireland.

The successful applicant will undertake work on pig production with special reference to increased efficiency, and will be required to undertake teaching duties in the Faculty of Agriculture, Queen's University, Belfast.

Appointment to the post may be at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level, the qualifications for which are:

SSO Over 25 and under 32 years of age with a 1st or 2nd Class Honours Degree in Agriculture and at least 4 years post-graduate experience, preferably in relation to pig production.

HSO Under 30 years of age with an Honours Degree as above and at least 2 years relevant post-graduate experience.

SO Under 27 years of age with an Honours Degree as above.

Grading and commencing salary will be related to qualifications and experience on the following scales:

SSO £2,798-£3,895 HSO £2,221-£2,834 SO £1,435-£2,329

Please write or telephone for an application form and further information, quoting Ref. SB 135/74/N to the Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26). Completed forms must be returned to arrive not later than 28th May, 1974. (1987)

NORTHERN IRELAND CIVIL SERVICE

Pathologist

Our Toxicology and Drug Safety Unit is expanding and has recently moved into new, well-equipped laboratories; an additional pathologist is now required to assist in the assessment of the safety of novel pharmaceutical compounds.

His (or her) main duty will be in the interpretation of histopathology but candidates should display an interest in the development of specialised procedures in related fields.

The successful applicant is likely to possess a degree in veterinary medicine or in a relevant Biological science and ideally would have prior experience in histology or histopathology; however, further training can be arranged where necessary.

A competitive starting salary will be paid, together with the fringe benefits which one associates with a large, British-based company. The Medicinal Research Centre is located one mile from Harlow New Town and Development Corporation property may be available to suitable candidates at an economic rent.

If you would like to be considered for this post, please write, outlining your career to date, to :–

(2014)

THE UNIVERSITY OF CALGARY

THE FACULTY OF MEDICINE

Applications and nominations are invited for the positions of Professor and Head, Division of

MORPHOLOGICAL SCIENCE

and Professor and Head, Division of

PHARMACOLOGY & THERAPEUTICS

The successful applicants will be expected to have an interest in undergraduate and graduate medical education and to be a well-established and active investigator.

The positions are to be filled Sept. 1/74 or as soon as possible. Salary will be according to qualifications and experience.

Nominations and/or applications will be received by Dr. L. E. McLeod, Dean, Faculty of Medicine, The University of Calgary, Calgary, Alberta, T2N 1N4, Canada, until July 1, 1974. Applications are to be accompanied by a detailed curriculum vitae.

THE UNIVERSITY OF CALGARY

(2027)

N.M.R. SPECIALIST

We are seeking a person, preferably at post-doctoral level, who is familiar with the use of a variety of modern N.M.R. instruments and techniques such as Fourier Transform equipment, and highly skilled in the interpretation of spectra. He must be interested in the application of these techniques to problem-solving in synthetic organic chemistry. An interest in the application of N.M.R. to biological problems related to medicinal chemistry would also be an advantage.

The job will involve supervision of the N.M.R. laboratory within the Analytical Department of the Scientific Development Group and the successful candidate will give advice on future expansion of this laboratory in line with current developments in the N.M.R. field.

We are a major international pharmaceutical company, part of the AKZO organisation and our laboratories are situated on the main M8 Edinburgh-Glasgow road. We offer a salary based on qualifications and experience, commensurate with the responsibility of the position. Conditions of employment are in keeping with the best modern practice.

Assistance with any relocation expenses will be given.

Write with details of age, qualifications and career to date to:—

Personnel Manager,
Organon Laboratories Limited,
Newhouse, ML1 5SH, Lanarkshire.

Organon

(2028)

QUEEN MARY COLLEGE
University of London
ORGANIC ELECTROCHEMISTRY

Applications are invited for an S.R.C. supported Postdoctoral Research Fellowship for collaboration with Dr. J. H. P. Utley on the development of aspects of cathodic synthesis. A versatile organic or physical-organic chemist is required. Appointment is for 2 years from October 1, 1974. Salary within range £2,118 to £2,412 p.a. plus £162 London Allowance.

Applications (giving age, qualifications and names and addresses of 2 referees) to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS. (2021)

DALHOUSIE UNIVERSITY
Nova Scotia, Canada
DEPARTMENT OF ANATOMY
TWO ASSOCIATE OR ASSISTANT PROFESSORS

Applications are invited from persons with a Ph.D. or a professional qualification for the above positions. Duties may include the teaching of Anatomy to Medical, Dental or Paramedical students. An ability to teach gross anatomy and a research interest in the nervous system would be an advantage. Salary (minimum $15,000) and rank commensurate with experience. Applications together with curriculum vitae and the names of two referees should be addressed to Dr. D. G. Gwyn, Department of Anatomy, Dalhousie University, Halifax, Nova Scotia, Canada by June 20, 1974. (1881)

COMMONWEALTH AGRICULTURAL BUREAUX
Vacancy for
SCIENTIFIC INFORMATION OFFICER
at the
COMMONWEALTH BUREAU OF SOILS
Rothamsted Experimental Station
Harpenden, Hertfordshire

Duties: Preparing abstracts for the abstracting journal "Soils and Fertilizers", which covers world scientific literature on soils and soil-plant relationships, and dealing with scientific enquiries within these fields.

Qualifications: A degree in soils or in agricultural science, or in sciences basic to these. Ability to write good and concise English essential. The successful candidate may be required to learn a foreign language. Experience or training in information work, including subject indexing, would be an advantage.

Salary: In scale £1,435 to £2,592 (bar) £2,798 to £3,478 (bar) £3,756 to £4,004, plus a compensatory allowance (taxable but not superannuable) of 4½% to offset personal contribution to F.S.S.U. Starting salary according to qualifications, experience and age.

Application forms: and full particulars from the Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN.

Closing date for applications: June 14, 1974. (1888)

UNIVERSITY OF SURREY
Guildford, Surrey GU2 5XH
DEPARTMENT OF CHEMISTRY

Applications are invited for a Science Research Council Postdoctoral Assistantship for work with Professor J. A. Elvidge and Dr. J. R. Jones on a study of tritium exchange in heterocyclic compounds. The appointment is available from 1/10/74 and will be for either one or two years. Salary £2,058 by £165 plus F.S.S.U. Applications together with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to one of the above-named persons. (1882)

UNIVERSITY OF EAST ANGLIA
SCHOOL OF ENVIRONMENTAL SCIENCES

Applications are invited for the position of Senior Research Associate to conduct research on a NERC supported project to investigate the chemistry of the sea surface microlayer. The post is suitable for someone with first degree training in chemistry and relevant post-graduate experience in chemistry or oceanographic/ atmospheric sciences. Knowledge of gas chromatographic techniques would be an advantage. The appointment is for one year initially, but is renewable for a further year. Salary will be on the scale £1,929-£2,223 per annum plus FSSU.

Further information is available from Dr. P. S. Liss, School of Environmental Sciences, University of East Anglia, Norwich, NOR 88C, to whom applications, quoting two referees, should be sent to arrive as soon as possible, but not later than 13 June 1974. (2046)

NATURE CONSERVANCY COUNCIL

Scientific Officers/Higher Scientific Officers

SALARY RANGE £1435 - £2854

Applications are invited for the following posts in the Nature Conservancy Council:

Scientific Officers/Higher Scientific Officers, Geology & Physiography Section.

The work of the Section includes the inspection, evaluation, selection and conservation of areas of geological importance, the provision of relevant advice and liaison with Government, University and other geologists and geographers and with land owners. The duties do not include geological and physiographical research.

Candidates for Scientific Officer posts should be under 27 years of age with a degree (or equivalent) in Geology and/or Physical Geography; for Higher Scientific Officer posts candidates should be under 30 years of age with the above qualifications and at least two years relevant post graduate experience. A current driving licence is essential.

Starting salary according to qualifications and experience.

Application forms and further particulars are available from Establishments (S), Nature Conservancy Council, 19 Belgrave Square, London SW1X 8PY. Please quote reference number E2/03/02.

Closing date for completed application forms: 14 June 1974. (2034)

UNIVERSITY OF KEELE

There will be two vacancies for Demonstrators in Geology from October 1, 1974. Applicants should possess good Honours degree and be keen to carry out research. Preference given to those particularly interested in mineralogy, petrology, or structural geology though others will be considered. Salary £1,626 per annum. Further particulars and application forms from the Registrar, The University, Keele, Staffs, ST5 5BG, to whom completed applications should be returned by June 20, 1974. (2062)

UNIVERSITY OF BIRMINGHAM ADMINISTRATIVE POSTS

CENTRE OF WEST AFRICAN STUDIES

to assist Director of a multi-disciplinary Centre—duties include student admissions, the administration of the Centre, the Centre Library: salary in Administrative III up to £2,412.

SCHOOL OF BIOLOGICAL SCIENCE

to assist the Chairman of an undergraduate School of six departments—duties include admissions, examinations, committee work, financial records: salary in Administrative III.

DEPARTMENT OF PHYSICS

to assist the Head of a large science department (c. 150 non-academic personnel): duties may include committee work, budgeting, graduate admissions, personnel work, conference organisation. Salary in Administrative II or III.

Candidates should be graduates preferably with previous administrative experience. Salary scale (after August) Administrative III £1,953 to £3,285; Administrative II £2,580 to £3,990 p.a. with F.S.S.U.

Further particulars and application forms available from Senior Assistant Secretary, University of Birmingham, P.O. Box 363, Birmingham B15 2TT to whom forms should be returned by June 7. (2063)

Postdoctoral Research Assistant

A Postdoctoral Research Assistant is required for the Division of Cellular Biology for research into the cellular biochemical response of synovial cells to phagocytosis of immune complexes. The appointment is for one year in the first instance. The work involves maintenance organ culture and microdensitometry and is part of a programme of work on the biochemistry of human rheumatoid synovium. Applications, including the names of two referees, to The General Secretary, Kennedy Institute of Rheumatology, Bute Gardens, Hammersmith, London W6 7DW. (2044)

Cardiovascular Research

Section Head, £4000+

Our cardiovascular teams have proved themselves capable of identifying new approaches to the treatment of heart disease. It is intended that these teams will form the basis of a new section in the department of Pharmacology and Biochemistry.

We need an established pharmacologist, someone with a minimum of 4 years' post-doctoral experience, capable of giving excellent leadership to this section. Good managerial potential is expected since the section will probably expand.

Future growth of cardiovascular research in Fisons will depend largely on your drive and creative ability. A contribution to other fields of drug research will also be expected through interaction with senior scientists in other departments.

Starting salary will be over £4000; benefits, including contributory pension, welfare schemes and expenses towards relocation are excellent.

Please write or telephone for an application form, quoting reference 355R:
John Mills, Personnel Manager,
Fisons Limited, Pharmaceutical Division, Bakewell Road,
Loughborough, Leics.
Tel: Loughborough 66361

FISONS

(2085)

EDITOR

required by chartered Society for monthly journal and news-sheet, annual review, Colour Index, text books and other publications on chemistry and technology of dye and pigment manufacture and application, all with world-wide circulation.

Salary depending on qualifications and experience, but not less than £2,500.

Apply in writing to Honorary Secretary, Society of Dyers and Colourists, Perkin House, P.O. Box 244, 82 Grattan Road, Bradford, Yorkshire BD1 2JB, marking envelope 'Confidential'. (2094)

UNIVERSITY OF SIERRA LEONE

Njala University College

Applications are invited for SENIOR LECTURESHIPS/LECTURESHIPS IN THE DEPARTMENT OF PHYSICS. Applicants must possess a good first degree in Physics, i.e. first or second class honours and must have some teaching experience in a University. Preference will be given to applicants with a higher degree. Appointees will be expected to teach any branch of Physics at general degree level. Salary scales: Senior Lecturer Le4,550 to Le5,400 p.a.; Lecturer Le2,400 to Le4,740 p.a. (£1 sterling = Le2). The British Government may supplement salary of Senior Lecturers by £1,600 p.a. (sterling) for married appointees or £1,000 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. These supplementation rates are currently under review. This supplementation is unlikely to be applied to appointments at Lecturer level. Superannuation scheme or gratuity; various allowances, family passages; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than June 10, 1974, to the Secretary, University of Sierra Leone, Private Mail Bag, Freetown, Sierra Leone. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90-91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (2065)

SUNDERLAND POLYTECHNIC

SCHOOL OF PHARMACY

LECTURER I or II IN PHARMACOLOGY AND PHYSIOLOGY

Preference will be given to graduates in Pharmacy but applications from graduates in Pharmacology will be considered. Applicants should have relevant postgraduate qualifications and/or experience.

The appointee will be required to participate in the teaching programme of the Department which includes honours degree courses in Pharmacy, Pharmacology and Physiology.

Appointment will be from September 1, 1974 or as soon as possible thereafter. Research and consultancy are encouraged.

Salary will be in accordance with the Burnham Technical Scale (at present under review).

Lecturer Grade I—£1,660 to £2,847.

Lecturer Grade II—£2,515 to £3,243.

The Education Authority is prepared to help the successful candidate(s) with removal expenses, and temporary lodging allowance.

Further particulars and an application form may be obtained from the Personnel Officer, Sunderland Polytechnic, Chester Road, Sunderland SR1 3SD, and should be returned not later than June 6, 1974. (2075)

CSIRO

AUSTRALIA

RESEARCH SCIENTIST

Commonwealth Meteorology Research Centre Melbourne, Vic.

The Commonwealth Scientific and Industrial Research Organization has a broad charter for research into primary and secondary industry areas. The Organization has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD Dynamic Meteorology

(Atmospheric/Pollution/Chemistry)

GENERAL:
The Commonwealth Meteorology Research Centre is a joint venture by the Commonwealth Scientific and Industrial Research Organization Division of Atmospheric Physics and the Commonwealth Bureau of Meteorology carrying out research in dynamical meteorology.

Current activities involve the development and use of general circulation models with major emphasis being placed on their use for geophysical experiments and the attainment of an improved understanding of atmospheric behaviour. In addition a large effort is devoted to the development and operational implementation of weather forecasting models and research into the problems of obtaining and assimilating initial data into such models.

DUTIES:
To undertake research in the General Circulation Group on dynamical problems associated with atmospheric composition and pollution. Several numerical general circulation models are available and the appointee will be expected to use these to investigate the possible effects of pollutants on the climate, and to develop expertise in relevant atmospheric compositional problems with a view to incorporating appropriate chemistry into the model.

QUALIFICATIONS:
A Ph.D degree or equivalent qualifications, and demonstrable research ability, preferably in the field of meteorology or fluid dynamics. Some experience in Atmospheric Chemistry would be an advantage.

SALARY:
The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: $A9,380-$A14,290 p.a. Outstanding applicants may be offered appointment at a higher level.

TENURE:
Either a fixed term or an indefinite appointment may be negotiated. An indefinite appointment carries Australian Government Superannuation benefits.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 424/15 should reach:—

The Personnel Officer,
Australian Scientific Liaison Office,
64-78, Kingsway,
London,
WC2B 6BD

by the 21st June, 1974

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
Washington, D.C. 20036, U.S.A.

(2086)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the following vacancy:-

TUTORIAL FELLOW

in the Department of Geology (Caledonian geology and/or Geophysics). Salary Range £1311 - £1473. Duties to commence as soon as possible. Closing date for applications 15 June 1974.

Applications, together with the names and addresses of two referees, should be forwarded to The Registrar, University College, P.O. Box 78, Cardiff, CF1 1XL from whom further particulars may be obtained. Please quote ref. 0566. (2058)

UNIVERSITY OF SIERRA LEONE

Fourah Bay College

Applications are invited for LECTURESHIP IN GEOGRAPHY, in any branch of the discipline, although preference will be given to those with a teaching and research interest in (a) Geomorphology; (b) Climatology/Hydrology; or (c) Social Geography. Appointee will be expected to teach both General and Honours degree students and conduct research in the chosen field. Salary scale: Le2,400 to Le4,740 p.a. (£1 sterling=Le2). The British Government may supplement salary in range £950-£1,300 p.a. (sterling) for married appointee or £350-£700 p.a. (sterling) for single appointee (normally free of all tax) and provide childrens education allowances and holiday visit passages. The supplementation rates are currently under review. F.S.S.U. Family passages; various allowances; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than June 11, 1974 to the Secretary, University of Sierra Leone, Private Mail Bag, Freetown, Sierra Leone. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (2066)

UNIVERSITY OF LONDON

King's College

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of LECTURER IN BIOCHEMISTRY, tenable from September 1, 1974. Candidates should be interested in teaching dental students and preferably have had relevant experience. The successful applicant will be primarily responsible for the planning and organisation of a new biochemistry course for dental students starting next session. He will be expected also to contribute to the teaching of medical undergraduates and Honours B.Sc. students.

From October 1, 1974, salary will be on the new scale for lecturers (£2,118 to £4,896 plus £162 London Allowance) with F.S.S.S.U. benefits.

Application forms and further particulars of the appointment are available from the Registrar, University of London King's College, Strand, London WC2R 2LS and should be returned to him by June 14, 1974, quoting reference N24/5. (2068)

UNIVERSITY OF IBADAN

Nigeria

Applications are invited for posts of (a) PROFESSOR and (b) SENIOR LECTURER and (c) LECTURER IN THE INSTITUTE OF APPLIED SCIENCE AND TECHNOLOGY. These posts are in the Engineering and Technology disciplines of Agriculture or Electronic Instrumentation or Food or Forestry or Petroleum or Wood. Candidates for (a) should hold a Ph.D. or equivalent in their field of specialisation as well as possessing widely recognised teaching, industrial and research experience. Administrative experience or ability for administrative duties are highly desirable qualities. Candidates for (b) should hold a Ph.D. or equivalent in their field of specialisation as well as significant teaching, industrial and research experience. Candidates for (c) should hold a Ph.D. or equivalent in their field of specialisation as well as the potential to perform effectively in teaching, industrial liaison and research. Salary scales: (a) N6,600 p.a. (b) N5,030 to N5,750 p.a.; (c) N2,760 to N4,830 p.a. (£1 sterling=N1.54). The British Expatriates Supplementation Scheme is unlikely to be applied to these appointments. Family passages; various allowances; superannuation scheme; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than June 11, 1974 to the Registrar, University of Ibadan, Ibadan, Nigeria. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (2067)

AHMADU BELLO UNIVERSITY
Nigeria

Applications are invited for posts of (i) READERS/SENIOR LECTURERS and (ii) LECTURERS IN PHARMACEUTICS AND PHARMACOGNOSY in the Department of Pharmacy and Pharmacology. Candidates for (i) should have experience in teaching in Pharmaceutical Technology, Physical Pharmacy or Pharmaceutical Microbiology. A good higher degree and research publications in the field of specialisation are essential. Candidates for (ii) should have a good honours degree and a higher degree in their field of specialisation. Salary scales: Reader N6,100 p.a.; Senior Lecturer N5,030 to N6,050 p.a.; Lecturer N2,760 to N4,830 p.a. (£1 sterling=N1.54). The British Government may supplement salaries of Readers and Senior Lecturers in range £1,050 to £1,150 p.a. (sterling) for married appointees or £500 to £600 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. For those appointed to clinical duties, supplementation may be in range £1,200 to £1,250 p.a. (sterling—if married) or £650 to £700 p.a. (sterling—if single). These supplementation rates are currrently under review. This supplementation is unlikely to be applied to appointments at Lecturer level. Family passages; various allowances; superannuation scheme; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be forwarded by airmail, not later than June 10, 1974 to the Registrar, Ahmadu Bello University, Zaria, Nigeria. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (2069)

UNIVERSITY OF EDINBURGH
AND
LOTHIAN HEALTH BOARD
Teaching and Research Centre
Western General Hospital
ADMINISTRATIVE ASSISTANT

Applications are invited from young men and women, preferably with a Degree in Science and some practical or research experience, for a post as Administrative Assistant at the Teaching and Research Centre, Western General Hospital. The post is tenable from July 1, 1974 or such later date as may be arranged. This post will appeal to those wishing to take up a career in Administration in a scientific organisation. It is hoped that the person appointed will have an interest and preferably some experience in the development of Audio-Visual Aids.

The initial salary will be at a suitable point on the scale £1,929 to £2,553 per annum (under review). Superannuation provision will be under F.S.S.U.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL to whom applications (6 copies) giving the names of three referees, should be sent not later than June 8, 1974. Please quote reference number 4003. (2073)

UNIVERSITY OF KENT
At Canterbury
Research Assistant in Biology

A RESEARCH ASSISTANT is required from October 1, 1974 to work on the growth kinetics of mixed populations of micro-organisms using continuous culture techniques. Applicants should have, or expect to obtain, a good Honours degree in microbiology, preferably with an interest in mathematical modelling of biological systems. Salary £1,593. Applications giving details of qualifications and experience with names of two referees to the Assistant Registrar, Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH by June 10. Please quote ref. A52/74. (2072)

ARMAGH OBSERVATORY
Northern Ireland

Applications are invited for the post of Astronomer. Salary £2,388 x £165 - £3,213 with the equivalent of F.S.S.U., the starting point of the salary scale will depend on the experience and qualifications of the successful candidate. The post is a research one and the candidate's main interest should be in Stellar Astronomy. Armagh Observatory shares the facilities of the Boyden Observatory. Three copies of application should be sent not later than 15th July, 1974 to the Secretary, Armagh Observatory. (2077)

GLASSHOUSE CROPS RESEARCH INSTITUTE

Plant Physiology Department

A. PHYSICIST (CROP PROCESSES)

required to develop a biophysics research programme on the definition of plant structure in quantitative terms and on its relation to within-plant physical functions, especially transport processes. Appointee will collaborate with physiologists and biometricians in a major programme of mathematical modelling of glasshouse crop processes. Applicants should have a good honours degree and at least four years' research experience, preferably in experimental physics, biophysics, or a related subject; experience of biological work desirable. Appointment as SENIOR or PRINCIPAL SCIENTIFIC OFFICER, depending on experience. Closing date 31st July.

B. INSTRUMENTATION PHYSICIST

required for Design & Development Section, to join a team developing scientific equipment to meet special research problems. Applicants should have a sound background in applied physics and measurement theory, aptitude and experience in instrument design and construction, and a degree, HNC or equivalent qualification, in an appropriate subject. Appointment as

SCIENTIFIC OFFICER or HIGHER SCIENTIFIC OFFICER, depending on experience. At least five years' post qualifying experience is normally required for appointment in the higher grade. Closing date 28th June.

Salaries:

Scientific Officer	£1,435 — £2,329
Higher Scientific Officer	£2,221 — £2,854
Senior Scientific Officer	£2,798 — £3,895
Principal Scientific Officer	£3,715 — £4,895

Starting salary depending in each case on qualifications and/or experience. Contributory superannuation scheme for both posts, with addition non-pensionable allowance to offset contributions.

Further particulars (state post A or B) from the Secretary to the Institute, Worthing Road, Rustington, Littlehampton, Sussex, to whom applications should be sent by appropriate date. (2095)

LEEDS AREA HEALTH AUTHORITY (TEACHING)
EASTERN DISTRICT

PHARMACEUTICAL ANALYST

Applications are invited from pharmacists or graduate chemists for the above post based at St. James's Hospital, Leeds.

The person appointed will be accountable to the Pharmacist in charge of the Laboratory but will be responsible for the work of the other technicians. The work involves some routine analysis with investigations into quality control techniques and analytical methods.

Salary will depend on age, experience and qualifications but will be in the range £1,680–£2,916.

Application forms are available from the Personnel Manager, St James's Hospital, Leeds 33144 Ext. 203/293 (2091)

SENIOR TEACHING FELLOWSHIP—ORGANIC CHEMISTRY
(Ref F11N)

Applicants should have interests in physical organic chemistry or in the chemistry of natural products. The appointee will have a particular responsibility for part of the first year laboratory. The appointment will be from February 1st 1975.

The research interests of the School are in the areas of solid state physics, chemistry and biochemistry.

Salaries: Senior Lecturer $A12,268 - $A14,308. Senior Teaching Fellow $A7,270 - $A8,698.

For further details of these posts and for the method of application, write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London, WC1H 0PF. The closing date for applications is **June 24th 1974.** (2082)

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF BIOLOGY
RESEARCH ASSISTANT

Applications are invited from graduates for the post of Research Assistant in the Marine Laboratory, Garelochhead.

The successful candidate will work on problems concerned with the biological effects of waste disposal in the Solway Firth. A considerable amount of field work is undertaken and the ability to drive is essential.

Salary within the rate £1401 - £2001 with placing according to qualifications and experience. Appointments for a period of up to three years.

Applications (quoting R15/74) to Dr. E. J. Perkins, Department of Biology, Royal College, University of Strathclyde, 204 George Street, Glasgow, G1 1XW. (2074)

FLATFORD MILL FIELD CENTRE GRADUATES

(females) wanted who would be interested in the post of Temporary Help (cooking) at Flatford Mill Field Centre whilst searching for permanent science appointments. Could attend interviews and leave at short notice if necessary. Would suit two friends. Write to The Warden, Flatford Mill Field Centre, East Bergholt, Nr. Colchester, Essex or telephone (reverse charges) East Bergholt (020-629) 283. (2078)

ROYAL POSTGRADUATE MEDICAL SCHOOL

University of London

OSTI on-line information retrieval project

Applications are invited for a post of Research Assistant in the Wellcome Library to be responsible for its participation, as a biomedical user centre, in an on-line bibliographical retrieval project which is being financed by the British Library, Research and Development Division (formerly OSTI). The systems principally involved will be the MEDLARS on-line retrieval systems, MEDUSA and MEDLINE and the person appointed will act as intermediary in on-line search formulation and evaluation.

Applicants should have relevant academic and library/information science qualifications or experience; no computer knowledge is required. The salary will be on a scale £1929 to £2553 per annum (plus £162 London Allowance) according to qualifications and experience. The post is available from 1st July and will extend until December 1975.

Further details from The Librarian, Miss E. M. Read, Telephone 01-743 2030 Ext 97.

Applications to the Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, DuCane Road, London W12 0HS by 7th June 1974. (2081)

GRIFFITH UNIVERSITY

Brisbane, Australia

SCHOOL OF SCIENCE

Griffith University will admit its first undergraduate students in March 1975. Its organisation is on a broad school of study basis and it has a commitment to interdisciplinary teaching. Applications are now invited from men and women for the following positions:

SENIOR LECTURESHIP—CHEMICAL PHYSICS

(Ref F10N)

Applicants should have expertise in one of the areas at the interface of physics and chemistry. The appointee will have a key role in the second year teaching programme, in which emphasis will be placed on areas of overlap between chemistry and physics. The appointment will be from March 1st 1975.

VICTORIA UNIVERSITY OF WELLINGTON

New Zealand

CHAIR OF APPLIED MATHEMATICS

In view of the impending retirement of Professor C. J. Seelye in May 1974 from the Chair in Applied Mathematics, applications for this Chair are invited from persons with suitable qualifications in the branch of classical or modern applied mathematics. There are three Chairs in the Department, covering the range of applied, pure and statistical mathematics.

The Mathematics Department works in close cooperation with the Department of Information Science and the Applied Mathematics Division of D.S.I.R., which are both situated in the same building as the Mathematics Department.

Salary range: NZ$13,863 to NZ$17,645 p.a. Superannuation on the FSSU basis and allowance for travel expenses.

Further particulars and application procedure available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close **31 July 1974.** (2083)

DEPARTMENT OF ANATOMICAL SCIENCES expects to have two faculty positions open for neurobiologists with active research programs in the development of the vertebrate nervous system or in the structure and function of mammalian nervous system.

Teaching responsibilities will include neuroscience for medical and dental students and graduate student training. Rank and salary will be determined by qualifications. Reply to Maynard M. Dewey, Chairman, Department of Anatomical Sciences, Health Sciences Center, SUNY, Stony Brook, N.Y. 11790, by June 30, 1974. Applications from women and members of minority groups are encouraged. (2032)

UNIVERSITY OF SHEFFIELD

DEPARTMENT OF PSYCHOLOGY

APPROACHES TO THE STUDY OF EARLY BEHAVIOURAL DEVELOPMENT

Nato Advanced Study Institute, Catania, Sicily, 1-10 September 1974. Topics covered include genotype-environment interaction. Growth of brain and nervous system, language development, cognitive growth. Perception and skills. Social integration.

Further information from Professor K. J. Connolly, Department of Psychology, University of Sheffield, Sheffield S10 2TN, U.K. (2031)

PLYMOUTH POLYTECHNIC

SCHOOL OF ELECTRICAL ENGINEERING

RESEARCH ASSISTANTSHIPS

Vacancies exist in the School for Research Assistants to work on projects in the following fields from September 1974.

1. Digital Techniques applied to Television.
   Qualifications:- Degree in Electronic or Electrical Engineering or Physics.
2. Computer-Assisted Learning Systems in Electrical Engineering.
   Qualifications:- Degree in Electronic or Electrical Engineering or Physics or Mathematics.
3. The application of Thin Film Technology in the Teaching of Engineering and Science.
   Qualifications:- Degree in Electronic or Electrical Engineering or Physics or Materials Science.

Applicants should hold or be expecting to obtain, a good honours degree, or an equivalent qualification in a relevant discipline such as those listed, and the successful applicant will be expected to register for a higher degree.

Further details and application forms are available from, The Establisment Officer, Plymouth Polytechnic, Plymouth PL4 8AA, and must be returned by 7th June, 1974. (2053)

MEDICAL RESEARCH COUNCIL

TISSUE CULTURE

Applications are invited for an appointment (Scientific Staff scale) to join a group studying the effects of inhaled substances on the lung. The team requires a member to undertake studies in cell culture with particular emphasis on the effects of particles on macrophages. Applicants should have post-doctoral experience in the relevant field. Duties to commence on 1 October 1974.

Apply giving details of age, qualifications, and the names of two refrees to: Director, MRC Pneumoconiosis Unit, Llandough Hospital, Penarth, Glamorgan, CF6 1XW. (2052)

TRAINEE HOSPITAL BIOCHEMIST

Applications are invited from science graduates (or those expecting to graduate this year) for a 2 year appointment leading to an M.Sc. in Clinical Biochemistry starting 1st October 1974. The successful applicant will be required to attend the University of Surrey (Guildford) for a total of three terms. Training in clinical biochemistry, which includes a research project, will be given within laboratories in the Avon Area, including those of the Southmead Health District and the Bristol Health District which constitute the clinical teaching hospitals of the University of Bristol.

Salary will be on the scale for Hospital Biochemists in the range £1497 - £2259.

Applications (including the names of two referees) should be submitted before 19th June to the Personnel Officer, Southmead Hospital, Westbury on Trym, Bristol BS10 5NB. (2010)

PORTSMOUTH POLYTECHNIC

RESEARCH ASSISTANTS

BioMolecular Research Group

One assistant for research on the synthesis, modification and function of chromosomal proteins. The project, which is supported by the Science Research Council and the Cancer Research Campaign, uses the naturally synchronous division cycle in the true slime mould Physarum polycephalum and a specific gene isolated from the same organism.

The research will be largely biochemical in nature.

Crystallographic Research Group

One assistant to work on structural problems of biological interest. The present programme of work includes the investigation of the molecular configuration of substrates of enzymes in the glycolytic pathway.

Crystal Growth Research Group

One assistant to work on crystal growth from high temperature solutions and on studies of crystal perfection and surface topography.

Applicants must have, or expect to have, a god honours degree in a science subject. There will be opportunity to register for a higher degree.

Salary Scale: £1,230-£1,330 per annum (under review)

Application forms and further particulars may be obtained from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ, to whom completed applications should be returned by 10th June 1974.

Please quote ref. S12. (2051)

UNIVERSITY OF SOUTHAMPTON LECTURER IN THEORETICAL PHYSICS

Applications are invited for the above post in the Department of Physics. Candidates should have an active research interest in Quantum Physics. It is expected that the successful candidate will have experience in the use of fields and groups, and will interact effectively with the Theoretical High Energy Physics group in the Department. Salary scale: £2118 - £4896. The initial salary will depend on qualifications and experience. Further particulars may be obtained from the Deputy Secretary's section (ext. 2400). The University, Southampton SO9 5NH, to whom applications (7 copies from United Kingdom applicants) should be sent not later than 14th June 1974, quoting reference number 229/A/Na (2002)

UNIVERSITY OF DURHAM

DEPARTMENT OF ENGINEERING SCIENCE

Applications are invited for the post of **TEMPORARY LECTURER IN ENGINEERING SCIENCE** for one year from 1 October 1974. Applicants should have teaching, research or professional experience in either electrical or civil engineering. The undergraduate course in Engineering Science consists of a unified course in civil, mechanical and electrical engineering followed by specialisation in the final year.

The salary will be on the scale £1929 - £4548 (under review) per annum with FSSU.

Applications (3 copies) naming three referees should be sent by Monday, 10 June 1974 to the Registrar and Secretary, Science Laboratories, South Road, Durham, DH1 3LE. (2004)

UNIVERSITY OF EAST ANGLIA

SCHOOL OF MEDICAL SCIENCES

Applications are invited for a S.R.C. Post-Doctoral Research Assistantship for one year in the first instance from 1 October 1974, to work on the magnetic circular dichroism of matrix-isolated molecules. A novel apparatus for this purpose has recently been constructed and is now operational. The investigation is to be extended to the study of the magnetic and optical properties of unstable molecules generated photochemically. Salary will be on a scale starting at £1929 per annum plus F.S.S.U., according to previous experience.

Applications as soon as possible either to Dr. R. Grinter or Dr. A. J. Thomson, School of Chemical Sciences, University of East Anglia, Norwich, NOR 88C. (2005)

YOUNG SCIENCE GRADUATE wanted to assist in the laboratory investigation of patients with degenerative arterial disease. Please write for application form to Mr. Dormandy, Surgical Unit, Clare House, St. George's Hospital, Tooting, SW17. (2008)

JUNIOR TECHNICIAN required for Department of Histopathology to assist in research on multiple sclerosis and immunity in relation to the nervous system. O.N.C. or Science A levels an advantage. Apply in writing to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, giving details of age, qualifications and experience, if any, and quoting Ref. H.P.1. (2013)

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF BIOCHEMISTRY

Applications are invited from graduates with good Honours degrees or from students graduating this June in either Biochemistry or Chemistry to undertake research leading to a higher degree. The research is in the field of Biophysical Chemistry and is concerned with the study of the properties of copolypeptides in aqueous solution. This is a CASE studentship in conjunction with Unilever Ltd. Applications, including the names of two refrees should be addressed to Dr. M. N. Jones, Department of Biochemistry, The University, Manchester, M13 9PL. (2047)

UNIVERSITY OF SOUTHAMPTON

DIRECTOR

University Computing Service

Applications are invited for the new full-time post of Director of the University Computing Service. The salary will be at an appropriate point within the University's professorial range and will consequently not be less than £5973 per annum. F.S.S.U. Further particulars may be obtained from the Academic Registrar, The University, Southampton SO9 5NH and applications (ten copies from applicants in the United Kingdom and one from others must be submitted before 30 June, 1974. (2009)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSICAL CHEMISTRY

Applications are invited for a temporary Research Assistantship at postdoctoral level on a two year project supported by the Science Research Council to investigate the structure of the electrical double layer in D.O. The post will involve both experimental and theoretical work and some experience in electrochemistry or related field is desirable. Commencing salary up to £2553 per annum (£2757 per annum after 1 October 1974).

Further information can be obtained from Dr. R. Parsons, School of Chemistry, Cantock's Close, Bristol BS8 1TS, to whom application giving curriculum vitae and the names of two referees should be sent as soon as possible. (2011)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PATHOLOGY

REPRODUCTIVE IMMUNOLOGY RESEARCH GROUP POST-DOCTORAL RESEARCH APPOINTMENT

Applications are invited from Science or Medical Graduates for a post of Research Assistant or Research Associate within a group investigating immunological aspects of mammalian reproduction. Preference may be given to candidates with previous experience in this field but applications from those with a suitable background in immunology, reproductive physiology or developmental biology will be considered.

The post is available immediately and for up to 3 years in the first instance, with a salary on the scale £1,929-£3,048 depending upon qualifications and experience. F.S.S.U. subject to the accord of academic status.

Applications (2 copies) should include details of name, age, education, qualifications, research experience, publications, and the names of two referees and be submitted not later than June 14th 1974 to Dr. W. D. Billington, Department of Pathology, Medical School, University Walk, Bristol BS8 1TD, from whom further particulars may be obtained. (2042)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF ORAL PHYSIOLOGY

Junior Research Associate

Applications are invited from graduates with an Honours Degree preferably in Biochemistry or Chemistry for a post as Junior Research Associate to assist in research into the fluoride of dental plaque with special reference to the prevention of tooth decay being undertaken in the Department of Oral Physiology. The appointment will be for a period of up to 3 years and provides an opportunity to work for a higher degree in the case of those who do not already hold such a qualification. Salary will be according to qualifications and experience on the scale £1,569-£1,818 per annum.

Applications should be submitted within three weeks of the appearance of this advertisement to Professor G. N. Jenkins, Department of Oral Physiology, The Dental School, The University, Northumberland Road, Newcastle upon Tyne, NE1 8TA. (2045)

UNIVERSITY OF BRISTOL

MATHEMATICAL STATISTICS

Applications are invited from probabilists and statisticians for the post of LECTURER IN STATISTICS in the School of Mathematics. The person appointed will have the responsibility for teaching undergraduates in a combined mathematics and statistics degree programme and for supervising the research of postgraduate students in Probability and Statistics. His own research interests should lie in the same fields. Ideally the candidate should be prepared to take up his duties from the autumn term 1974, but candidates whose commitments preclude their availability before January 1975 will be considered.

The salary will be on the revised scale £2,118-£3,813 per annum.

Further particulars may be obtained from the Secretary, University Senate House, Tyndall Avenue, Bristol BS8 1TH, to whom applications should be sent by 7th June 1974 (please quote reference EB). (2041)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PATHOLOGY

A vacancy exists for a Research Technician, Grade 3, (with O.N.C. or equivalent) to join a small new team studying cellular hypoxia; experience in tissue culture is essential, and in histology desirable. The duties will involve the preparation and maintenance of brain-cell and fibroblast cultures, plus some histological and general preparative work. This is a 'funded' post, tenable at the School of Veterinary Science, Langford, and it carries a salary within the scale £1,650 x £54 to £1,920 p.a. The present grant, which is renewable, runs to December 1977 initially. Applications in writing, giving the names and addresses of two referees to Professor I. A. Silver, Department of Pathology, Medical School, University Walk, Bristol BS8 1TD. (2043)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF METALLURGY

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for the post of RESEARCH ASSISTANT under an S.R.C. grant to Dr. H. A. Davies for research on the formation, structures and properties of NON-CRYSTALLINE ALLOYS PRODUCED BY ULTRA-RAPID QUENCHING OF MELTS. This is an interesting and established programme of research on a new class of materials that promise to find important commercial applications in the near future, for instance, as high strength reinforcing filaments. Candidates should possess or expect to obtain shortly a Ph.D. degree in Metallurgy, Materials Science or Physics. Experience in electron microscopic, X-Ray diffraction or calorimetric/D.T.A. techniques would be an advantage. Tenable for one year in the first instance, renewable for a further period to 30 June 1977. Starting salary in the range £1,929-£2,223 (under review), with F.S.S.U. provision. Further particulars from the Registrar and Secretary, The University, Sheffield S10 2TN to whom applications should be sent by 7 June 1974. Quote Ref. R.74/G. (2030)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BOTANY

Lecturer in Ecological Genetics

Applications are invited for the above post commencing on 1st October, 1974. Applicants should possess a good honours degree and post-graduate experience in the ecological genetics of plants, plant breeding or plant population biology. Interest and experience in quantitative or mathematical approaches would be an advantage.

There will be excellent opportunities for collaborating with an active teaching and research group in evolution, population biology and plant breeding.

Initial salary within the range £2,118 - £2,412 per annum on a scale rising to £4,896 per annum.

Applications together with the names of three referees should be received not later than 22nd June, 1974, by the Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote ref RV/276028/N. (2040)

TECHNICIAN

required to assist in immunological research in gastrointestinal disease. Laboratory experience involving immunological and histological methods advantageous. Commencing salary according to experience and qualifications within scale £1,440 to £1,509 plus £126 p.a. L.W. Apply, The Secretary, St. Mary's Hospital Medical School, Paddington, London W2 1PG quoting Ref. MUW. (2070)

THE UNIVERSITY OF LANCASTER DEPARTMENT OF BIOLOGICAL SCIENCES

PLANT PHYSIOLOGIST

Applications are invited for a 3-year post-doctoral appointment supported by N.E.R.C. The research will consist of a study of the responses of plants to SO_2 and NO_2 pollution. The post is suitable for post graduate students in whole-plant physiology or ecologists with experience of physiological methods who are expecting to graduate this year. Salary: £2,118 to £2,247 to £2,412.

Further particulars may be obtained (quoting reference L.828/C) from the Establishment Officer, University House, Lancaster LA1 4YW, to whom applications (5 copies), naming three referees, should be sent not later than June 8, 1974. (2100)

UNIVERSITY OF NEW SOUTH WALES

PROFESSOR OF GEOGRAPHY

This is an additional chair in the School of Geography within the Faculty of Applied Science. The new professor will share in the further development of this recently established school. He will be responsible for undergraduate and post-graduate courses in economic geography and in human geography generally, and will be expected to foster and supervise research in economic geography by staff and postgraduate students. Experience in applied economic geography is desirable. The present head of the School is Professor J. A. Mabbutt. Professor M. Chaikin, Dean of the Faculty of Applied Science, will be in England during June. Anyone who wishes to see him should write to the University Appointments Office (P.O. Box 1, Kensington, N.S.W. 2033, Australia) by 24 May 1974.

Salary: $A19,102 per annum. Subject to the consent of the University Council, professors may undertake a limited amount of higher consultative work. The University reserves the right to fill any chair by invitation.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on **28 June 1974.** (2036)

UNIVERSITY OF NEW BRUNSWICK

DEPARTMENT OF BIOLOGY

SCANNING ELECTRON MICROSCOPY TECHNICIAN

Required to operate and maintain a Cambridge S4-10 scanning electron microscope and related equipment. Duties will include specimen preparation, photography, and possibly some transmission electron microscopy. Most work will be with biological material.

Previous experience of scanning electron microscopy would be advantageous, but training will be given where necessary.

Starting salary up to $9,000 depending on qualifications and experience.

Application with names of two referees to Dr W. D. Seabrook, Department of Biology, University of New Brunswick, Fredericton, N.B., Canada. (2097)

McGILL UNIVERSITY

DEPARTMENT OF BIOLOGY

CHAIRMAN

Applications and nominations are invited for the abovementioned position which will be open on June 1, 1975. The Department of Biology consists of 51 full-time and affiliated academic staff representing most areas of biology with emphasis on Cell, Molecular and Developmental Biology, Ecology, Human Genetics and Neurobiology.

Qualifications sought include evidence of scholarship in research, skill in teaching, and administrative experience. Inquiries, nominations and applications (accompanied by a curriculum vitae and names of at least three referees) should be directed to:

Dean E. J. Stansbury
Faculty of Science
McGill University
P.O. Box 6070
Montreal H3C 3G1
CANADA (2096)

KING'S COLLEGE, LONDON
JUNIOR TECHNICAL OFFICER

An assistant is required to help with electron microscopy and diffraction studies in a laboratory which investigates macromolecular structure and function in muscle and other contractile systems. Previous experience in electron microscopy though desirable, is not essential. Applicants should have H.N.C. or two Science or Maths A levels, or equivalent. Salary is in the range of £1,173 to £2,073 (+ £126 London allowance), according to age and qualifications. Please write, giving full personal details, to Mr. J. Cribbin, Department of Biophysics, King's College, 26-29 Drury Lane,WC2.
Closing date June 14. (2099)

BIOCHEMIST

Applications are invited for a postdoctoral research position for work on the plasma membrane of **Dictyostelium discoideum** during aggregation and differentiation. A background in either membrane biochemistry or carbohydrate biochemistry would be helpful but is not essential. The appointment is available September 1, 1974 at a salary of $8,700.

Applications with full curriculum vitae and the names of three referees should be sent to Dr G. Weeks, Department of Microbiology, University of British Columbia, Vancouver, B.C., V6T 1W5, Canada.

Further details available on request. (2098)

SENIOR BIOCHEMIST

required by a leading British pharmaceutical Research Organisation, to initiate and direct research projects in the areas of pharmacokinetics, drug metabolism, molecular pharmacology and enzymology in association with the design and development of new medicines. Persons with appropriate experience are invited to apply in writing for further details to The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB, marking the envelope CONFIDENTIAL.
(2090)

TOXICOLOGISTS/ PHARMACOLOGISTS

Honours Graduates/Post-Doctoral Fellows, with experience, required for Research and Short and Long Term Toxicological Studies of compounds of potential therapeutic importance. Excellent opportunities for advancement in modern, well-equipped laboratories. Pension and Assurance Scheme. Application forms from The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (2089)

PHARMACOLOGISTS

Graduates/Post-Doctoral Fellows, with or without experience, required for Research and the Screening of Compounds of potential therapeutic importance and in the elucidation of their mode of action and toxicity. Vacancies are open for both Senior and Junior Pharmacologists. Excellent opportunities for advancement in modern, well-equipped laboratories. Application forms from The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (2088)

FELLOWSHIPS AND STUDENTSHIPS

Liverpool Polytechnic
SCHOOL OF PHARMACY

SRC Studentship in Medicinal Chemistry

Applications are invited from candidates with a good honours degree in Pharmacy or Chemistry, or Grad. R.I.C. to work for a Ph.D. degree on the project "4-phenylpiperidine derivatives as potential non-addicting analgesics". The work will involve organic synthesis and stereochemical studies.

The project is a CASE award and the co-operating body is Allen and Hanburys Ltd., usual S.R.C. stipend applies which may be supplemented by payment for teaching duties and income during the industrial period.

Enquiries and applications to Dr. A. F. Casy, School of Pharmacy, N. Liverpool Polytechnic, Byrom Street, Liverpool, L3 3AF. (2033)

Lakehead University

DEPARTMENT OF CHEMISTRY
Post-Doctoral Research Fellowship

Several Post-Doctoral Fellowships are available at present for work in the following fields:

Kinetic and thermodynamic studies of gas/solid reactions (R. A. Ross)
Polymer photochemistry; dielectric studies of polymers (N. A. Weir)
Dielectric relaxation studies in organic liquids and solids (J. Crossley)

The fellowships will carry salaries up to $8,500 per annum. Applicants should state their preferred field of interest and forward a full curriculum vitae including the names of three referees to:

Mr. D. E. Ayre, Secretary, Lakehead University, THUNDER BAY "P", Ontario, Canada. P7B 5E1.
(2057)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF COLOUR CHEMISTRY AND DYEING
WOLFSON ORGANIC POWDERS RESEARCH UNIT

Research Studentship Research Assistantship
Post-Doctoral Fellowship

Applications are invited for the above research posts to work on polymorphism in organic solids and the stabilisation of metastable organic dispersions. Current research in the Unit includes studies on the nucleation and growth of dye and pigment particles, their physico-thermal stability and the influence of conditions of precipitation on application properties. The research may be extended to include the study of pharmaceutical preparations and organic intermediates used in colour and related industries.

Applicants for the RESEARCH STUDENTSHIP should possess, or expect to be about to be awarded, a good honours degree in Physics or Chemistry. The terms will be equivalent to a Research Council Studentship and the holder will register for a Ph.D. degree. (Ref. No. 39/2/D).

Applicants for the RESEACH ASSISTANTSHIP should have similar qualifications but may not necessarily wish to read for a higher degree. This post will be initially for one year, with possible renewal, on the scale £1449 - £1818. (Ref. No. 39/3/D).

The appointment to the POST-DOCTORAL FELLOWSHIP will be for one year in the first instance, with possible renewal, at an initial salary of £1929 (under review) with F.S.S.U. (Ref. No. 39/4/D).

Applicants should give previous experience and the names and addresses of two referees. Forms of application and further particulars from the Registrar, The University, Leeds LS2 9JT (Please quote appropriate reference number). Closing date 1 July 1974. (2026)

RESEARCH STUDENTSHIPS IN PHARMACOLOGY

Applications are invited from graduates in pharmacology, biochemistry or physiology for Research Scholarships, to work on projects in neuropharmacology and immunopharmacology. Successful applicants will be expected to register for a higher degree.

Applicants should send their c.v. and names and addresses of two referees to Professor J. L. Mongar, Department of Pharmacology, UNIVERSITY COLLEGE LONDON, Gower Street, London WC1E 6BT. (1913)

UNIVERSITY OF LEICESTER
GEOLOGY
N.E.R.C. STUDENTSHIPS 1974/5

Applications are invited for three Postgraduate Studentships in the following three topics:

(1) Chemistry of diagenetic carbonate cements (Dr. J. D. Hudson).

(2) Geochemistry and mineralogy of stalactitic mineral deposists (Dr. T. D. Ford).

(3) Geophysical studies of the Gregory Rift, Kenya (Dr. M. A. Khan).

Successful applicants will be expected to register for a higher degree.

Enquiries should be sent to Dr. C. H. James, Department of Geology, The University, Leicester LE1 7RH. (1957)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF MATHEMATICS
Semiconductor Theory

Applications are invited for RESEARCH STUDENTSHIPS (C.A.S.E.) supported by the Science Research Council, which are available for theoretical work to investigate recombination and related problems by use of quantum mechanics and statistical mechanics. There will be contact with experimental work at Ferranti Limited and with government research laboratories. Posts are tenable for up to three years, and the work will be supervised by Professor P. T. Landsberg.

A good honours degree in Mathematics, Physics, Engineering Science or similar qualifications is essential and registration for an M.Phil. or a Ph.D. degree is encouraged.

Please apply as soon as possible giving the name of a referee to the Academic Registrar, The University, Southampton SO9 5NH. (1958)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF PHYSICS
POSTDOCTORAL RESEARCH FELLOW

Applications are invited from suitably qualified candidates for the above post, to join the magnetism group in an experimental investigation of the thermal expansion of magnetic materials near the critical temperature.

The post is financed by the Science Research Council and will be tenable for two years from October 1, 1974. The initial salary will be up to £2,223

Further details may be obtained by writing to the Deputy Secretary, The University, Southampton SO9 5NH to whom applications, giving brief curriculum vitae and the names of two referees should also be sent Please quote reference number: 226/R/Na. (1959)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY
RESEARCH STUDENTSHIPS

Application are invited from graduates, or from those who expect to graduate this summer, for Research Studentships to undertake research work for higher degrees. The Department has a wide research interest in several areas of physiology and biochemistry.

Further details and application forms obtainable from Postgraduate Admissions Office, Department of Physiology and Biochemistry, Medical and Biological Sciences Building, The University of Southampton, Bassett Crescent East, Southampton SO9 3TU. (1961)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF CHEMISTRY

Applications are invited for the post of Lecturer in the Department of Chemistry. Candidates should have interest in any branch of Physical Chemistry. Salary scale: £2,118 to £4,896. The initial salary will depend on qualifications and experience. Further particulars may be obtained from the Deputy Secretary's Section (Ext. 2400), The University, Southampton SO9 5NH, to whom applications (7 copies from United Kingdom applicants) should be sent not later than June 14, 1974. Please quote reference number: 193/A/Na. (1962)

HERIOT-WATT UNIVERSITY - EDINBURGH
Postgraduate Research Studentships in Department of Physics
Prof. S. D. Smith **Tel. 031-449 5111**

Applications are invited for SRC, NERC and University Research Studentships tenable for 3 years from September 1974. The principal research interests of the Department are in solid state and laser physics, non-linear optics, tunable laser spectroscopy and satellite meteorology. Active and substantial projects are current on applications of the spin-flip Raman laser, opto-acoustic spectroscopy with tunable dye lasers and the remote measurement of atmospheric temperature and pressure from satellites. (1851)

THE UNIVERSITY COLLEGE OF WALES
Aberystwyth
DEPARTMENT OF BIOCHEMISTRY
RESEARCH STUDENTSHIP

The Science Research Council is prepared this year to offer to a suitable candidate a C.A.S.E. Research Studentship, tenable at this College. The studentship will be jointly supervised by Dr. P. W. Trudgill of the Department and Dr R. E. Cripps of Shell Research Ltd.

The successful candidate will be expected to spend about three months of each year at the Shell laboratories and for the remainder of the year will be based at Aberystwyth.

The project, a study of the metabolism of aromatic organophosphate insecticides by microorganisms, including pathway studies and the purification and characterization of associated mixed function oxygenases, is expected to lead to a higher degree.

Candidates should either have or expect to obtain this year a Class I or II (i) degree in Biochemistry. The studentship will commence on October 1, 1974 and will be tenable for up to three years. The value of the award is currently £695 per annum plus approved fees.

Enquiries and applications should be made as soon as possible to Dr P. W. Trudgill, Department of Biochemistry, University College of Wales, Aberystwyth. (Tel. 0970 3111, Ext. 100). (1967)

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL STUDIES
S.R.C. C.A.S.E. POSTGRADUATE STUDENTSHIP

Applications are invited for a Research Studentship for studies on the role of hormone receptor proteins in the regulation of nuclear R.N.A. synthesis in plants. Candidates should hold or expect to gain a First or Upper Second Class Honours degree in Biochemistry, Botany or a related subject. The successful applicant will be expected to register for the degree of Ph.D.

Those interested should write to Dr D. Grierson, Department of Physiology and Environmental Studies, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough LE12 5RD as soon as possible. (1968)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
DEPARTMENT OF BIOCHEMISTRY
M.R.C. RESEARCH STUDENTSHIP

Applications are invited for an M.R.C. studentship which is available from October 1974. Candidates should hold a good Honours degree in chemistry or a biological science. The successful candidate will pursue a course of research, leading to a Ph.D. degree, involving a study of changes which occur in the protoplast membrane of *Bacilus amyloliquefaciens* during the secretion of extracellular enzymes with particular regard to the metabolism of membrane phospholipids.

Applications and enquiries should be made to Dr G. Coleman or Dr D. White, Department of Biochemistry, University of Nottingham Medical School, University Park, Nottingham NG7 2RD. Telephone 0602 56101. (1970)

RESEARCH STUDENTSHIP

Applications are invited for a three-year research studentship to study aspects of the vitamin requirements of the Golden hamster (**Mesocricetus auratus**). Applicants should have or expect to attain this summer, first or upper second class honours degree in nutrition, or a relevant biological discipline. The successful candidate who will register for further degree, will receive a grant plus a small travel and book allowance, and fees will also be paid.

Applications with names of two referees and short curriculum vitae should be made to Dr. D. J. Ford, Medical Research Council, Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM5 4EF, from whom further details may be obtained. (2019)

UNIVERSITY OF EDINBURGH
RESEARCH FELLOW

A science or clinical graduate (Lecturer scale) is required for a research fellowship tenable for two years in the first instance in the Clinical Immunology Laboratories in the Royal Infirmary and No. 2 Forrest Road, Edinburgh, under the direction of Dr. W. J. Irvine. The successful applicant would be involved in the study of immune complexes in the sera of patients with cancer. A post-doctoral fellow is preferred, but applications from others are welcome.

Applications giving full details of age, qualifications and previous experience should be sent as soon as possible to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL. Please quote reference number 5020. (1978)

UNIVERSITY OF ABERDEEN
UNIT FOR RESEARCH ON ADDICTIVE DRUGS

A S.R.C. Studentship (Co-operative Award in Science and Engineering, C.A.S.E.), will become available on October 1, 1974. It is tenable for 3 years in co-operation with the Pharmaceutical Division of Reckitt and Colman Ltd., Hull, and is open to First and Upper Second Class Honours Graduates in Pharmacology, Biochemistry or Physiology. The research project is concerned with the action of newly-synthesized morphine-like compounds on neurotransmitter release and on behavioural patterns in normal and morphine-dependent animals.

Applications (3 copies) to be submitted to Professor H. Kosterlitz, from whom further particulars may be obtained, University of Aberdeen, Marischal College, Aberdeen AB9 1AS, not later than May 31, 1974. (1844)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
DEPARTMENT OF PHYSIOLOGY
Cardiovascular Research

Applications are invited from honours graduates or prospective honours graduates in physiology, pharmacology or a related discipline, for a studentship for training in research methods tenable from October 1974. The holder will be eligible for registration as Ph.D. student of the University. The value of the award and conditions of appointment will be those of M.R.C. Studentships.

Facilities are available for the postgraduate student to join a group working on several aspects of autonomic nervous control of the cardiovascular system in animals and in man, under the supervision of Dr. P. H. Fentem. Applicants should write to Dr. Fentem giving a brief curriculum vitae and the names and addresses of two referees, at the Department of Physiology, The Medical School, University of Nottingham, Nottingham NG7 2RD. (1820)

UNIVERSITY OF LONDON
King's College
RESEARCH STUDENTSHIP IN BIOCHEMISTRY

An S.R.C. research studentship is available for three years from October 1974 leading to a Ph.D. degree. The successful candidate will work with Dr. C. J. Chesterton on a project in eukaryotic molecular developmental biology.

Applicants should hold, or expect to attain, a first or upper second class honours degree in biochemistry or an allied subject.

Applications (naming two referees) should be sent to Professor H. R. V. Arnstein (N), Department of Biochemistry, King's College, Strand, London WC2R 2LS. (2020)

UNIVERSITY OF KEELE
RESEARCH STUDENTSHIP IN CHEMISTRY

Applications are invited for a Co-operative award in Science and Engineering (C.A.S.E.) for a graduate to carry out an investigation of volatile pheromones in insects (Dr E. D. Morgan) jointing with Rothamsted Experimental Station, Harpenden, Herts. The usual regulations for S.R.C. studentships apply. Information and application forms from Dr Morgan, Chemistry Dept., Keele University, Keele, Staffs. ST5 5BG. (1976)

THE DENTAL SCHOOL
UNIVERSITY OF BIRMINGHAM

Applications are invited from graduates in Biochemistry or Chemistry for a Research Studentship available in the Department of Oral Pathology in the Dental School. The project, which will be suitable for registration for a Ph.D., is on the subject of the composition and properties of the organic components of biological calcifications. The investigation will have particular reference to dental plaque and its mineralisation but a comparative approach involving study of microbial calcification and both normal and pathological calcifications is envisaged. No specialised dental background is required.

The award is of £695 p.a. (subject to review) plus the payment of fees for Ph.D. registration.

Further details may be obtained from the Assistant Registrar, The Dental School, St. Chad's Queensway, Birmingham B4 6NN, to whom applications, including curriculum vitae and names of three referees, should be sent. (1984)

UNIVERSITY OF EDINBURG
RESEARCH STUDENTSHIPS IN CHEMISTRY

Applications are invited for CASE studentships, financed by the Science Research Council, and tenable for 3 years from 1st October, 1974 for research in catalytic oxidation, colloidal stability, reactions of excited oxygen, or heterocyclic cyclo-addition reactions, and for another studentship for heterogeneous caavsis.

Applicants should write before 15th June, 1974 giving brief curriculum vitae and the names of two referees to Professor C. Kemball, Department of Chemistry, University of Edinburgh, West Mains Road, Edinburgh, EH9 3JJ. (1992)

QUEEN ELIZABETH COLLEGE
(University of London)
Atkins Laboratories
Campden Hill, London W8 7AH

Applications are invited for two S.R.C. C.A.S.E. Studentships for research into the chemistry of degradation and stabilisation of polymers. The research would involve work in one or more of the following areas: synthetic organic chemistry, organometallic chemistry, polymer chemistry and isotopic tracer techniques; for which excellent facilities are available. There will be a close collaboration with the Research Department of I.C.I. Plastics Division, Welwyn Garden City, where the students will spend a short time each year. Applications, together with the names of two referees should be forwarded to the Secretary, Chemistry Department (N), as soon as possible. (2023)

UNIVERSITY OF
NEWCASTLE UPON TYNE
SCHOOL OF CHEMISTRY
SCIENCE RESEARCH COUNCIL C.A.S.E. STUDENTSHIPS

Applications are invited from suitably qualified candidates for three C.A.S.E. studentships to be held in the Department of Organic Chemistry from October 1974 for research leading to the Ph.D. degree.

The usual conditions of eligibility and stipend for S.R.O. Studentships apply.

One award associated with Imperial Chemical Industries, Pharmaceuticals Division, will be concerned with a study of metal complexes of physiologically active molecules. Another award associated with Bush Boake Allen Ltd., will be for the study of novel methods of terpene synthesis using organometallic and other intermediates. The third award associated with Beecham Research Laboratories will be concerned with the synthesis of penicillin and cephalosporin analogues.

For further details and application forms write to Mr. S. J. Hall, The School of Chemistry, The University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU. (2016)

IMPERIAL COLLEGE OF
SCIENCE AND TECHNOLOGY
DEPARTMENT OF BOTANY
RESEARCH FELLOWS

One or more Research Fellows, expected to assist in undergraduate teaching preferably in plant physiology, or cytology and ultrastructure, or phylogeny and taxonomy, and to undertake independent research, are required from October 1, 1974.

Applicants should normally hold a Ph.D. degree. Given this qualification, the initial salary will be in the range of £2,118 to £2,412 plus £162 London allowance. Appointments will be renewable annually up to a maximum of 3 years.

Further details available from Professor A. J. Rutter, Department of Botany, Imperial College of Science, Prince Consort Road, London, S.W.7, to whom applications, giving details of education experience and research interests, and the names of two academic referees, should be made by June 14. (2025)

UNIVERSITY OF KENT
AT CANTERBURY
RESEARCH FELLOW IN CHEMISTRY

Applications are invited for a post-doctoral research fellowship, initially for one year with the possibility of extension, to work with Professor R. F. Hudson on Radical Rearrangements and e.s.r. Spectroscopy. Salary £2118 (1974/75 scale). Application forms and particulars from the Assistant Registrar, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH. Closing date 7th June. Please quote ref. A35/74. (2001)

UNIVERSITY OF IBADAN
Nigeria

Applications are invited for the following posts:-

1. LECTURER/MEDICAL RESEARCH FELLOW IN NUTRITION in the Food Science and Applied Nutrition Unit. Candidates must be registered medical practitioners with post-graduate training on one or more of the following: Nutrition, Public Health, Child Health. Preference will be given to those with field experience in any or all of these fields in an African environment. There are possibilities of further training in the field of Nutrition. Duties of appointee, will include co-operation with members of staff in research of Public Health Nutrition, including the assessment of nutritional status of communities and the planning and execution of applied nutritional programmes; teaching of public health nutrition to medical students and other paramedical staff and the awakening of awareness of nutrition in the general population.

2. LECTURER IN MEDICAL BACTERIOLOGY in the Department of Medical Microbiology. Candidates must be medically qualified, have a Diploma in Bacteriology or equivalent and have appropriate experience in teaching, research and diagnostic work. Interest and experience in the clinical application of the subject in the tropics would be an advantage, particularly in the field of Microbiology of Venereal Diseases. Appointee (1) must be experienced in advising clinical colleagues on the treatment of patients, when requested to do so and (2) organise and supervise diagnostic service for the Venereal Diseases and Treponematosis Research Unit. The post carries honorary Consultant appointment at the University College Hospital, Ibadan.

Salary scales: Lecturer (Consultant Status) N4,880 - N5,800 p.a. Research Fellow (Medical Clinical) N3,960 - N5,800 p.a. Lecturer (Non Consultant) N3,960 - N4,830 p.a. Lecturer/Research Fellow (Medical Pre-Clinical) N2,760 - N4,830 p.a. (£1 sterling=N1.54). The British Expatriates Supplementation Scheme is unlikely to be applied to these appointments. Family passages; various allowances; superannuation scheme; biennial overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, not later than 12 June 1974 to the Registrar, University of Ibadan, Ibadan, Nigeria. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further particulars may be obtained from either address. (2085)

UNIVERSITY OF KENT
AT CANTERBURY
Tutorial Fellowship in Biochemistry

Applications are invited for the post of Tutorial Fellow in Biochemistry. Preference will be given to candidates with an interest in mammalian biochemistry of physiology. The appointment would be for 3 years and the salary, depending on age and qualifications, inthe range £2,118 to £2,412 (1974/75 scale). Application forms and particulars may be obtained from the Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH. Closing date for applications: June 14, 1974. Please quote ref. A51/74. (2024)

UNIVERSITY OF YORK
DEPARTMENT OF PHYSICS
POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post from as early a date as possible for a period of two years. The successful applicant will work on the construction and evaluation of a scanning Auger electron microscope. The project is sponsored by the R. W. Paul Fund of the Royal Society and the research wil involve modifying a UHV scanning electron microscope equipped with a field emitting source so as to present images derived from the output of a concentric hemispherical electron energy analyser. Experience in these or related topics would be an advantage.

Salary £2118 - £2247, with FSSU.

Three copies of applications, naming two referees, should be addressed by 15 June 1974 to the Registrar, University of York, Heslington, York, Y01 5DD, from whom further details are available. Please quote reference number 11/6017. (2003)

UNIVERSITY COLLEGE CARDIFF
Department of Applied Mathematics and Astronomy

Applications are invited from those possessing or expecting to have a first or Upper Second Class Honours Degree in Mathematics or Physics for a CASE studentship in collaboration with the Royal Radar Establishment, Malvern. The work involves the calculation of energies of formations of vacancies using Greens' function methods and applicants will be expected to register for a Ph.D. Applications to Dr. T. Lukes, Dept. of Applied Mathematics and Astronomy, University College, P.O. Box 78, Cardiff, CF1 1XL. Please quote ref. 0563. (2012)

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF PHARMACEUTICAL CHEMISTRY
DRUG METABOLISM UNIT PROSTGRADUATE STUDENTSHIPS

Applications are invited from Honours graduates and students in their final year of undergraduate study in Pharmacy, Chemistry or Biochemistry for postgraduate studentships available for research in the Drug Metabolism Research Unit leading to a higher degree. Current research includes investigation of metabolic pathways, analytical methodolgy in pharmacokinetics, protein-binding and drug interactions, and studies on conjugating and desulphurating enzymes.

Studentships will provide for the payment of fees and a maintenance allowance of not less than £675 for students living in hostel or lodgings.

Applications to Professor J. B. Stenlake, Department of Pharmaceutical Chemistry, Royal College, University of Strathclyde, 204 George Street, Glasgow, G1 1XW. (2060)

HERIOT-WATT UNIVERSITY, EDINBURGH
DEPARTMENT OF BREWING & BIOLOGICAL SCIENCES

Applications are invited for a S.R.C. CASE research studentship for studies on the role of polysaccharides in the molecular architecture of cereal grains. The co-operating body is the Brewing Industry Research Foundation.

Applicants must hold a first or upper second class honours degree in chemistry or biochemistry.

Further details may be obtained from Professor D. J. Manners, Heriot-Watt University, Chambers Street, Edinburgh, EH1 1HX. (2056)

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF BIOCHEMISTRY
RESEARCH STUDENTSHIP

An M.R.C. research studentship is available for the Department of Biochemistry, for work in the field either of Biochemical Pharmacology (including pharmacokinetics), or in the Biochemistry of Reproduction, including ovarian, pituitary and uterine metabolism. Extensive facilities are available for work in these areas.

Applicants, who should possess or expect to possess a good Honours Degree in Biochemistry, Pharmacology, or a relevant subject, should submit applications to Professor P. J. Heald, Department of Biochemistry, University of Strathclyde, Royal College, 204 George Street, Glasgow, G1 1XW from whom further information can be obtained. (2059)

UNIVERSITY OF ST. ANDREWS
DEPARTMENT OF BIOCHEMISTRY
S.R.C. Postdoctoral Research Fellowship

Applications are invited from candidates with a Ph.D. for the above post tenable for two (possibly three) years from July, 1974. The work will involve the development of immobilised enzyme structures and the evaluation of these materials as analytical reagents in automated analysis. Starting salary £1929; F.S.S.U. Applications, with the names of 2 referees, should be sent to Dr. W. E. Hornby, Department of Biochemistry, University of St. Andrews, Fife by 7th June, 1974. (2055)

THE UNIVERSITY OF ASTON IN BIRMINGHAM
DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for RESEARCH STUDENTSHIPS in:—

1 The metabolic, nutritional and endocrine aspects of fish culture.
2 The physiology and biochemistry of isolated islets of Langerhans.

Candidates will be expected to have at least a 2(1) degree in Biology, Biochemistry or Physiology.

Further details are available from Professor A. J. Matty, Department of Biological Sciences, The University of Aston, in Birmingham, Gosta Green, Birmingham B4 7ET. (2048)

UNIVERSITY OF ABERDEEN
GENETICS DEPARTMENT
RESEARCH STUDENTSHIPS

Applications are invited for Postgraduate Studentships leading to a Ph.D. Degree. Research interests in this Department include chromosome polymorphism, comparative study of DNA organization, mutagenesis and repair, recombination, plant biochemical genetics, ecological genetics of plant and animal populations, human cytogenetics, etc.

Applications, with names of two refrees, should reach Professor F. W. Robertson, Department of Genetics, Zoology Building, 2 Tillydrone Avenue, Aberdeen, AB9 2TN, not later than June 7th, 1974. (2054)

UNIVERSITY OF ESSEX
N.E.R.C. RESEARCH STUDENTSHIP—Geological Sciences

Applications are invited for postgraduate studies into (i) mechanisms of deformation and recovery in carbonate rocks and (ii) the microstructure of stony meteorites. Electron microscopy, a new technique to the geological sciences, will be central to both projects.

The studentship, tenable in the Physics Department, is open to students with good honours degrees and has a value of £695 plus fees (under review).

Applications should be made to Dr. D. J. Barber, Physics Department, University of Essex, Wivenhoe Park, Colchester C04 3SQ. (2050)

UNIVERSITY OF BRISTOL
Long Ashton Research Station
POST DOCTORAL FELLOWSHIP

Applications are invited for a post-doctoral fellowship, sponsored by a consortium of wine companies, to investigate the anti-microbial effects of sulphur-dioxide and sorbic acid on wine spoilage yeasts, in studying the quantitative effect of inhibitors on micro-organisms. Experience in the use of isotopes

Applicants should have a doctorate and experience would be an advantage.

The appointment will be for two years, the starting date is by agreement. Salary £2,413 -£2,497 per annum.

Applications to the Secretary, Research Station, Long Ashton, Bristol, BS18 9AF, **by 17th June, 1974,** from whom application forms and further particulars can be obtained. (2080)

THE AUSTRALIAN NATIONAL UNIVERSITY
RESEARCH SCHOOL OF CHEMISTRY
Fellows or Senior Fellows

The School proposes to make up to three appointments in research areas primarily concerned with organic chemistry, and one appointment in the area of physical chemistry.

The appointments would be at the level of Fellow or Senior Fellow, for five years in the first instance with the probability of re-appointment to retiring age. These classifications, which are particular to the Australian National University, span in terms of salary and status the categories lecturer to reader in other Australian Universities.

Applications in the following fields are of particular interest to the School:

- Physical organic chemistry
- Synthetic organic chemistry, with emphasis on photochemical, electrochemical or other novel procedures.
- Theoretical chemistry related to organic applications and
- Physical aspects of the photochemistry of organic solids.

Applicants for the post in the physical-theoretical group should have interests complementary to photochemical research already represented in the School in visible and ultraviolet spectroscopic photochemical studies (Dr. J. Ferguson, Professorial Fellow), EPR and NMR (Dr. R. Bramley, Fellow), and theoretical work (Professor D. P. Craig). Possible areas are structoral and other aspects of defective solids in relation to photochemistry and topochemistry.

The organic group of the School works under the guidance of Professor A. J. Birch, Mr. R. W. Rickards (Professorial Fellow), and Dr. J. K. MacLeod (Senior Fellow).

The appointees would principally conduct independent research, with some support by post-doctoral workers and Ph.D. students, and would be expected to assist with other aspects of post-graduate training and School administration. The School is non-departmental, and opportunities exist for co-operation with other groups in the School.

The School is well equipped to contemporary standards, especially in optical, NMR and EPR spectroscopy, mass spectrometry, X-ray crystallography and cryogenics. There are comprehensive workshop facilties. In computing there is access to the School PDP 11 and the University Univac 1108 systems.

Salary on appointment will be in accordance with qualifications and experience within the ranges: Senior Fellow $14,308 - $16,462 per annum, Fellow $10,432 - $14,288 per annum. All amounts are in Australian currency. Current exchange rates are approximately $A1 : 67 NP : $US 1.49.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation is on the FSSU pattern with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

There is no application form. Applicants should supply by **15 July 1974** a curriculum vitae, list of publications, a statement of research interests, and the names and addresses of three academic referees together with tow passport-sized photographs.

G. E. Dicker
Acting Academic Registrar

P.O. BOX 4,
Canberra, ACT, 2600
Australia. (2037)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
DEPARTMENT OF BIOCHEMISTRY
S.R.C. CASE Studentship

Applications are invited from graduates who hold Honours Degrees in Chemistry, Biochemistry, Biology or related subjects at the First or Upper Second Level, and from those who hope to have such qualifications by October, 1974, for a C.A.S.E. Studentship concerned with research into sterol ester metabolism in mammalian skin. This will be carried out mainly at the University of Nottingham and in part at the Environmental Safety Division, Unilever Research Laboratory, Colworth House, Bedford, and should lead to a higher Degree.

Research will entail a study of sterol ester metabolism in relation to other lipids in skin, with particular emphasis on prostaglandins, and will also involve fractionation of mammalian skin into its constituent components and cell types, subcellular fractionation of skin, and the effect of environmental change upon sterol ester metabolism in skin.

Further details and application forms may be obtained from Professor J. N. Hawthorne, Department of Biochemistry, The Medical School, The University of Nottingham, Nottingham NG7 2RD. (2092)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for the following:

RESEARCH SCHOOL OF PHYSICAL SCIENCES
Research Fellow/Postdoctoral Fellow in Theoretical Physics

The Department of Theoretical Physics has an academic staff of fifteen headed by Professor K. J. Le Couteur, FAA. For this appointment preference will be given to applicants interested in statistical mechanics. The permanent staff members in this area are Dr. K. Kumar and Dr R. J. Baxter. The Department also has research interests in the general field of nuclear physics, elementary particle physics and solid state physics.

Closing date: **14 June 1974.**

SALARIES: Salary on appointment will be in accordance with qualifications and experience within the ranges: Research Fellow $A8,698 - $11,901 per annum, Postdoctoral Fellow $A8,698 - $11,901. Current exchange rates are approximately $A1 : 67NP : $US1.49.

OTHER CONDITIONS—Tenure: Research Fellow normally for three years in the first instance with possible extension to a maximum of five years; Postdoctoral Fellow for not less than one year and not more than two years.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation is on the FSSU pattern with supplementary benefits.

Travel expenses from overseas (except New Zealand) are not paid for posts at the level of Senior Tutor but assisted passage can be considered for a person offered appointment from the United Kingdom who intends to settle permanently in Australia

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF for further particulars before applying. (2038)

UNIVERSITY OF BATH
S.R.C. STUDENTSHIPS IN BIOCHEMISTRY

ENZYME CHEMISTRY AND TECHNOLOGY RESEARCH STUDENTSHIP

The project will involve the study of active sites of dehydrogenases using fluorinated substrates. This research is part of a general programme using ^{19}F n.m.r. to study enzyme—substrate interactions.

C.A.S.E. STUDENTSHIP IN CONJUNCTION WITH UNIGATE LTD.

Membrane surface glycoproteins of the mammary cell will be studied using the milk fat globule membrane as a convenient large scale source of membrane material. The major membrane glycoprotein will be isolated and structurally characterised. Its contribution to surface antigenic effects will be examined using immunochemical techniques.

Applications for the above are invited from candidates who have or expect to receive a first or upper second class Honours Degree in Biochemistry or Chemistry. Full particulars should be included in a letter addressed to Registrar (S), The University, Bath BA2 7AY, quoting reference 74/85. (2061)

CHELSEA COLLEGE
University of London

Applications are invited for the post of POST-DOCTORAL RESEARCH FELLOW as member of an S.R.C. supported team investigating THE INTERACTION OF THE HUMAN THERMO-REGULATORY AND CARDIOVASCULAR CONTROL SYSTEMS in collaboration with the Engineering in Medicine Laboratory at Imperial College.

The successful candidate will probably be a Physiologist with an interest in human experimentation and data analysis, but applications from candidates with other backgrounds but a real interest in the project will be welcomed.

The appointment will be for three years commencing as soon as possible. Salary £1,746 to £1,920 to £2,091 per annum. Superannuable. Application forms from the Personnel Office, Chelsea College, Manresa Road, London SW3 6LX. (2064)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF CHEMISTRY
Atmospheric photochemistry of sulphur dioxide

Applications are invited for a S.R.C. supported post-doctoral RESEARCH FELLOWSHIP. The work will involve both kinetic and spectroscopic techniques in the near and vacuum ultra-violet regions.

Salary: £2,118 to £2,412 plus F.S.S.U.

Further details may be obtained from Drs J. A. Kerr and J. P. Simons (021-472 1301) or the Assistant Registrar (S), P.O. Box 363, Birmingham B15 2TT, to whom applications (3 copies) naming 3 referees by June 21, 1974. Please quote reference: NC4. (2087)

UNIVERSITY OF WARWICK
POSTDOCTORAL RESEARCH FELLOW IN MOLECULAR BEAM SCATTERING

Applications are invited for an SRC Postdoctoral Research Fellowship in the Department of Molecular Sciences to work on the investigation of four centre ion-molecule reactions. This will include experimental work using an existing crossed molecular beam apparatus at the Thornton Research Centre and the calculation of potential energy surfaces and scattering calculations. The applicant should have experience in high vacuum work and preferably in molecular beams. The post is available immediately and will be for one year in the first instance with the possibility of renewal for a further two years. The starting salary will be in the range £2,118-£2,580 p.a. with FSSU. Application forms and further particulars may be obtained from the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No: 42/Q/74; completed applications should be returned as soon as possible. (2029)

UNIVERSITY OF GLASGOW
DEPARTMENT OF CHEMISTRY
RESEARCH STUDENTSHIPS

Applications are invited for SRC CASE Research Studentships for work on the following topics: Prostaglandin Synthesis using Optically Active Precursors (directed by Dr. A. J. Baker in collaboration with Reckitt & Colman Ltd.); Synthetic Reactions involving Stabilised Carbanions (Dr. E. W. Colvin; I.C.I. Ltd., Pharmaceuticals Division); β-Lactam Derivatives related to Cephalosporins (Dr. E. W. Colvin; Pfizer Ltd.) and; Sulphur-Bridged Bicycle Systems (Dr. P. H. McCabe; I.C.I. Plant Protection Ltd.). Applications, including a brief curriculum vitae and the names of two referees, should be sent to Professor G. W. Kirby, Chemistry Department, University of Glasgow, Glasgow, G12 8QQ.

In reply please quote Ref. No. 3466M (2039)

MSc in Biodeterioration of Materials

Applications are being considered now for the 1974/75 session starting in September. SRC Advanced Course Studentships are available to suitable candidates.

Details and application form from
Administrative Assistant
Department of Biological Sciences
Portsmouth Polytechnic
Park Road, Portsmouth
Tel. Portsmouth (0705) 27681 Extn. 322

(2049)

BRUNEL UNIVERSITY
SCHOOL OF BIOLOGICAL SCIENCES
Part-Time Masters Courses

Applications are invited for admission to the following 2-year part-time postgraduate courses beginning in October.

1. M.Sc. in Applied Immunology
2. M.Sc. in Brain Studies
3. M.Sc. in Applied Cell Science and Virology
4. M.Tech in Weed Biology
5. M.Tech. in Environmental Pollution Science

Applicants for these courses should normally possess an honours degree in an appropriate subject.

Further information can be obtained from The Secretary, School of Biological Sciences, Brunel University, Uxbridge, Middlesex, U.K. (2079)

LECTURES AND COURSES

FEBS Advanced Course No. 32

Ion Transport and Mitochondrial Function

Budapest 31 August—1 Sept. 1974

This Advanced Course will take the form of a colloquium in which a panel of experts will lead discussions on (1) Transport of Substrate Anions: Mechanisms and Physiological Implications; (2) Relationship between Proton Transport and Mitochondrial Function; and (3) Transport of Cations: Mechanisms and Physiological Implications.

Participants may be able to present 10-minute communications on relevant results.

Fee: Swiss Fr. 30.00.

Enquiries as soon as possible to Dr. A. Fonyo, H-1082 Budapest, Ülloi ut 78/a, Hungary. (1842)

'ETTORE MAJORANA' CENTRE FOR SCIENTIFIC CULTURE

INTERNATIONAL SCHOOL OF THEORY AND APPLICATION OF COMPUTERS

3rd Course: DATA. Erice, Sicily. 2–21 September 1974

TOPICS: Transmission and Networks; Storage and Access; The Rôle of Small Computers; Special Processors.

PARTICIPANTS on the average will have a few years' experience in one of these topics and will wish to extend their knowledge in the wider field.

COST (fees plus board and lodging) 1,000 Swiss Francs.

Further details/applications to: Dr T. Massam, CERN 1211 Geneva 23, Switzerland. (2093)

GRANTS

LARGE TELESCOPE USERS

Further to the preliminary announcement regarding applications for time on the Anglo-Australian Telescope, it is still not yet known exactly what auxiliary equipment will be available during the first half of 1975, but some observations at the prime focus and the Cassegrain focus will be possible. Applications for time from January to June 1975 inclusive are invited, and should reach Mr. C. A. Murray at the Royal Greenwich Observatory, Herstmonceux Castle, Sussex by June 10, 1974. (2076)

Vol. 3
A. E. Needham
The Significance of Zoochromes

By **Arthur E. Needham,** Department of Zoology, South Parks Road, Oxford, Great Britain
With 54 figs. XX, 429 pp. 1974. Cloth DM 68,–; US $26.20
ISBN 3-540-06331-5

Prices are subject to change without notice

After considering the molecular basis of color, the chemical classes of zoochrome, their distribution among animals and within their bodies, the author concentrates on the functions of zoochromes. He deals first with physiological functions, those based primarily on physical properties, and then with biochemical functions, based primarily on chemical properties. In the rest of the book he seeks to assess the extent to which all zoochromes have functional significance. This involves considering their relationships to excretory metabolism and to pathological, reproductive, and developmental conditions, the sophistication of physiological and genetic controls of chromogenesis, and the evolution of biochromes. A further aim is to test the unity and validity of "chromatology" as a subject. The book represents a new departure and is addressed to zoology teachers and students, zoologists, physiologists, and biochemists. It will also appeal to chemists with an interest in biology.

YOUR FUTURE IN ELECTRON OPTICS...

WILL YOU WANT TO ENJOY THE BENEFITS OF SEM... WITHOUT ANY OF THE WORRIES?

Without question, scanning electron microscopy (SEM) is becoming an indispensable tool in many laboratories.

The trouble is, most SEM's are complicated to operate. Microscopists who really need top performance know how difficult this is to achieve. So they worry... about keeping the field of view on the monitor screen during specimen tilting or rotation... about electron beam contamination... about focus, exposure, contrast and alignment - all of which seem to demand simultaneous attention.

If you're such a worrier, your worries are over. **There's a Philips microscope for you now. The PSEM 500.**

This instrument represents, not merely a step, but a long jump into the future of SEM. Its unique eucentric goniometer keeps the field of view on the screen through 370° rotation or 51° tilt. Movement is controlled 10 times more accurately than with normal differential drives and digital indication enables you to make quantitative measurements. You focus with one knob-and all other controls are at your fingertips. Vacuum is guaranteed to 10^{-7} Torr, so you're always looking at the **specimen.**

A superb instrument... ahead of its time. **Send now for full details.**

Surface H-2 antigen concentration requirement of somatic hybrid cells for IgM-mediated cytotoxicity—*N. Rubio* 461
Subunit structure of HL-A antigens on cell surface—*L. Ostberg, J. B. Lindblom and P. A. Peterson* 463
Evidence that mitogenic lectins induce changes in lymphocyte membrane fluidity—*R. E. Barnett, R. E. Scott, E. T. Furcht and J. H. Kersey* 465

Some Recent ACADEMIC PRESS Titles of International Appeal

Third Edition
SOLUTION OF EQUATIONS IN EUCLIDEAN AND BANACH SPACES
by ALEXANDER M. OSTROWSKI
A Volume in the PURE AND APPLIED MATHEMATICS Series
1973, 432 pp., $34.00

RADIOISOTOPE AND RADIATION PHYSICS
AN INTRODUCTION
by MILORAD MLADJENOVIC
translated by SONJA SUBOTIC
1973, 256 pp., $19.00

THEORY AND APPLICATIONS OF VARIABLE STRUCTURE SYSTEMS
edited by R. R. MOHLER and A. RUBERTI
1972, 242 pp., $9.50

THE BIOGENESIS OF MITOCHONDRIA
TRANSCRIPTIONAL, TRANSLATIONAL AND GENETIC ASPECTS
by A. M. KROON and C. SACCONE
1973, 574 pp., $19.00/£9.10

CHEMISTRY IN BOTANICAL CLASSIFICATION
NOBEL SYMPOSIUM NO. 25
by GERD BENDZ and JOHAN SANTESSON
A Volume in the Nobel Symposia Medicine and Natural Science Series
1974, 320 pp., $27.50/£13.20

TREATISE ON ANALYSIS
Volume 4
by J. DIEUDONNE
A Volume in the PURE AND APPLIED MATHEMATICS Series
1973, 432 pp., $28.00

FLIGHT TO AMERICA
by KRISTIAN HVIDT
A Volume in the STUDIES IN SOCIAL DISCONTINUITY Series
1974, in preparation

COMPARATIVE BIOCHEMISTRY OF PARASITES
edited by H. VAN DEN BOSSCHE
1972, 512 pp., $16.50/£7.60

BASIC MECHANISMS IN HEARING
by AAGE R. MOLLER
A Volume in the ROYAL SWEDISH ACADEMY OF SCIENCE SYMPOSIUM Series
1973, 972 pp., $28.00

BASIC SLEEP MECHANISMS
edited by OLGA PETRE-OUADENS and JOHN D. SCHLAG
1974, 342 pp., $23.50/£11.00

GENETICS OF SEX DIFFERENTIATION
by URSULA MITTWOCH
1973, 256 pp., $16.50/£7.75

Third Edition
IN TWO VOLUMES
METHODS OF ENZYMATIC ANALYSIS
edited by HANS-ULRICH BERGMEYER
translated and edited by D. H. WILLIAMSON
Volume 1/1974, in preparation

Guide to authors

Nature accepts three types of communications:

● Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

● Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

● 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (*a*) is preferred to e^a if '*a*' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Hb K Woolwich the cause of a thalassaemia—*A. Lang, H. Lehmann and P. A. King-Lewis* 467

Effect of β-N-oxalyl-L-α, β-diaminopropionic acid on glutamate uptake by synaptosomes—*J. Lakshmanan and G. Padmanaban* 469

Quasi morphine-abstinence syndrome—*H. O. J. Collier, D. L. Francis, G. Henderson and C. Schneider* 471

Neurotrophic control of colchicine effects on muscle?—*T. Lømo* 473

Pseudorotation mechanism of ATP hydrolysis in muscle contraction—*J. H. Young, J. McLick and E. F. Korman* 474

In vivo enhancement of tyrosine hydroxylation in rat striatum by tetrahydrobiopterin—*R. Kettler, G. Bartholini and A. Pletscher* 476

Increased myocardial cathepsin D activity during regression of thyrotoxic cardiac hypertrophy—*K. Wildenthal and E. A. Mueller* 478

Vasopressin release from the isolated neurohypophysis induced by a calcium ionophore, X-537A—*Y. Nakazato and W. W. Douglas* 479

Capillary permeability and sympathetic activity in canine subcutaneous adipose tissue—*M. Intaglietta and S. Rosell* 481

Intracellular electric responses to sound in a vertebrate cochlea—*M. J. Mulroy, D. W. Altmann, T. F. Weiss and W. T. Peake* 482

Behavioural and physiological bases of drinking inhibition in water deprived rats—*E. M. Blass and W. G. Hall* 485

Optical polarisation indicates linear arrangement of rhodopsin oligosaccharide chain in rod disk membranes of frog retina—*G. Romhányi and L. Molnár* 486

Adaptation to invisible gratings and the site of binocular rivalry suppression—*R. Blake and R. Fox* 488

Memory in enzyme membranes—*A. Naparstek, J. L. Romette, J. P. Kernevez and D. Thomas* 490

Correlation between speed of pollen tube growth and seedling height in *Zea mays* L.—*D. L. Mulcahy* 491

Heterocyst formation in a blue-green alga, *Cylindrospermum*—*P. M. Reddy and E. R. S. Talpasayi* 493

SCIENCE STUDIES

Science Studies is a quarterly journal of interest to all scholars concerned with the social aspects of science and technology. It publishes original research from historians, philosophers, sociologists, political scientists and economists on the social and intellectual dimensions of science, science and public affairs, science and development and science in international relations.

Recent research reports include:
Theorists on Ingenious Mechanics: Joseph Henry Defines Science, Arthur P. Molella and Nathan Reingold. **Paradigms and Normal Science in Psychology,** Walter B. Weimer and David S. Palermo. **The Development of Specialities in Social Science: the Case of Ethnomethodology,** Nicholas C. Mullins. **Towards a Theory of Science Policy,** Karl Kreilkamp. **'D & R' Allocations in the United States,** Harold Orlans. Edited by Dr. Roy MacLeod, Science Policy Research Unit, University of Sussex, and Dr. David Edge, Science Studies Unit, University of Edinburgh. Published by Macmillan Journals Ltd.

Annual Subscription £8.50 (£9.50 U.S.A. and Canada). Prices applicable only to orders started before 31st December, 1974. Payment made be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

MARINE POLLUTION BULLETIN

Marine Pollution Bulletin is published monthly and sets out to cover all aspects of the fight for life of lakes, estuaries, seas and oceans. It includes news, comment, reviews and research reports not only on the threats of noxious substances to marine life but also on the management and productivity of the marine environment in general. It publishes accounts of new and proposed research programmes as well as the results of those in progress.

Recent research reports include:
Distribution of Caesium-137 in British Coastal Waters, D. F. Jefferies, A. Preston and A. K. Steele. **Export of Lead from Salt Marshes,** M. Banus, I. Valiela and J. M. Teal. **International Scope of Marine Pollution Damage,** D. P. Tihansky. **Effects of Red Mud on Marine Animals,** R. A. A. Blackman and K. N. Wilson. **Pollution Problem of the Golden Horn,** M. Karpuzcu.

Annual Subscription £6.50 (£7.50 USA and Canada). Prices applicable only to orders starting before 31 December 1974. Payment may be made in any currency at the current exchange rate. Cheques should be made payable to Macmillan Journals Ltd., Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

Differentiation

Differentiation, published bi-monthly, provides the opportunity for interdisciplinary communication. This journal offers up to date information and synthetic views of a problem underlining the whole biological phenomenon – differentiation. It aims to cover the following areas of study: embryonic differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions in vivo and in vitro, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Recent papers include:
Degree of differentiation in non-proliferating cells of mammary carcinoma, C. V. Wylie, P. K. Nakane and G. B. Pierce. **DNA synthesis and the production of antibodies by lymphoid tissues,** G. Harris. **The principle of sequential dependence in cellular differentiation,** P. A. Riley. Edited by: Dimitri Viza. Faculté de Médecine Pitié Salpétriere, Paris.

Annual subscription £20 (£22.00 U.S.A. and Canada). Prices applicable only to orders started before 31st December, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

SCIENCE & POLITICS

Jean-Jacques Salomon

The most original account yet of science's inextricable link with political power and the benefits and dangers of this close association. Based on world wide information concerning science policies, data and cases, Jean-Jacques Salomon presents a new definition of the scientist's role in society.

Nuclear hypocrisy in India

'NOTHING will better serve the interests of those who are hostile to us than for us to lose our sense of perspective and to undertake measures which would undermine the basic progress of the country. We believe that to be militarily strong, it is equally important to be economically and industrially strong'. Thus Mrs Gandhi in 1968 in declaring that India would develop her atomic energy programme exclusively for peaceful purposes. In the strictest sense, the recent detonation by India of a nuclear device does not violate any of the carefully worded statements of the past. But if the Indian government believes it can explain away its possession of nuclear devices by careful wording of statements, and can justify a peaceful-purposes programme on economic grounds it is guilty of wicked hypocrisy. Whatever the celebrations in India, scientists there should know that they gain no increased respect from scientists in other countries for producing a nuclear explosive, rather they lose it for being party to such a transparent deception.

The explosion was detonated in the Rajasthan desert—a mere 90 miles from the Pakistan border—and had a yield of 10 or so kilotons. It was fired sufficiently close to the surface (perhaps no deeper than 100 metres) so that it produced a large crater, the purpose of which, apparently, is water storage. There are no immediate reports of radioactive leakage so the experiment must have been done with some delicacy. There have been several cratering shots both in the United States and the Soviet Union and the literature on the subject is relatively open.

Can a nuclear explosives programme be purely peaceful? There is nothing in the science and technology which differentiates between peaceful and military devices, so the distinction can only be in the mind of the firer. Whatever Mrs Gandhi may say about her own intentions she is not going to dismantle the devices when she resigns from office, and her successor could well have much more aggressive intentions. Even in Mrs Gandhi's term of office a political situation could easily arise in which the Government 'with the greatest reluctance' was forced to consider the option of commandeering peaceful devices for warlike purposes. Thus India possesses all the psychological and physical ingredients for a nuclear deterrent and deceives none of its neighbours by talking about making holes and mining copper. The means of delivery are also there in the form of Canberra bombers; despite recent pronouncements India does not need missiles to become a military nuclear power to be reckoned with.

Can India afford it? It costs several hundred million pounds to develop nuclear devices. The cost of the hole in the desert and of any future project could if produced in more conventional ways hardly amount to this—and could employ and feed large numbers of people. If the programme is to be justified on its peaceful benefits, and is not to 'undermine the basic progress of the country' the government has a lot of explaining to do to its people, particularly the hungry ones. For a country with a GNP per capita of £40 there are surely more effective economic ventures than this.

What will be the impact on other potentially nuclear countries? The test is bound to trigger concern in Pakistan, but a more important question is the reaction of many other countries with nothing to fear from India. There are several abstainers from the Non-Proliferation Treaty who are bound to feel increasing pressure as a result of India's action, notably Israel and South Africa. India has compounded the seriousness of the situation by showing not only that even a poor country can make nuclear devices but also that there is a way in which they can be given some sort of flimsy justification in terms of peaceful uses.

Two golden opportunities have been lost. If India had been prepared to press her need for peaceful nuclear explosives in international circles, it is not out of the question that she could have been responsible for establishing some sort of agency which would have removed peaceful explosions from their present national basis. And if the present nuclear countries had busied themselves more over nuclear arms control in the past 5 years, they would have a better moral platform from which they could harangue proliferators.

100 years ago

AN excellent device has been forwarded to us for use in field-club excursions. It is designed to promote an interest in common flowers, and can of course be varied and worked without a prize. It consists of a large envelope, with a description, but not the name, of a plant, and directions as to what ought to be done with the plant when found. The particular envelope, forwarded to us by Mr. Higgins of the Liverpool Naturalist's Club, contains the following on its back :—

EXTRA PRIZE.

DESCRIPTION OF PLANT.

Leaves opposite, Sessile, Lanceolate, Acuminate.
Sepals 5, half as long as the 5 deeply-cleft Petals.
Stamens 10, Styles 3, height about 12 in.

Members finding a plant answering to this description should take it to the President or Botanical Referee, with their name signed at the foot of this slip. When correct the slips will be initialed and handed to the Secretary. The finder should be prepared to answer questions on the description; but the name of the plant will not be officially announced till after tea.

A Prize or Prizes will be awarded at the end of the Season to those most successful.

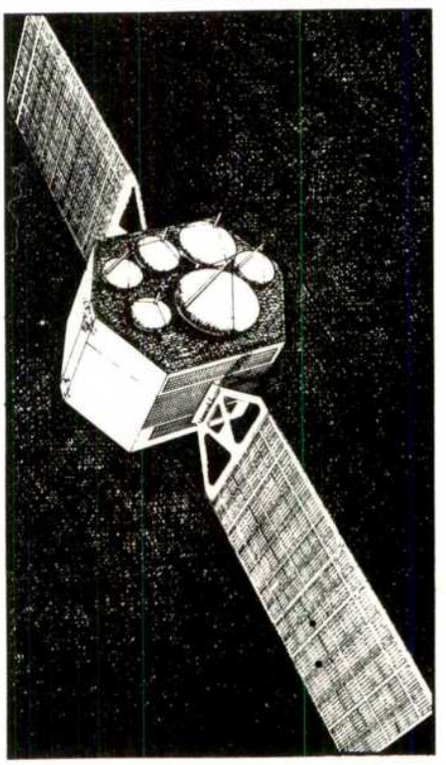
European space looks forward to the 1980s

This survey is by Adam Dattner, Assistant Director of ESRO.

THE new unified European Space Agency (ESA) is scheduled to come into being next month. It will carry on with the execution of various space programmes which have already been decided on and initiated in the framework of ESRO (the European Space Research Organisation).

The accomplishments of ESRO so far have been mainly in the field of scientific space missions, and the seven scientific satellites launched between 1968 and 1972 have all been remarkably successful. This record of technical success has resulted in a number of scientific achievements, mainly in magnetospheric physics and astronomy but also in solar physics and aeronomy. In particular, remarkable ultraviolet observations of stars have been made with high spectral resolution, as well as one of the first attempts at measuring celestial γ rays.

Four of the satellites launched are still in orbit and operating successfully. In particular two highly eccentric orbit satellites, HEOS A1 and HEOS A2, which measure the properties of magnetospheric plasma, solar wind and the interplanetary magnetic field out to some 30 Earth radii. ESRO IV, in a near-Earth orbit, measures a variety of charged and neutral particles, their temperature, density and composition–particles typical of the upper ionosphere as well as those of solar origin. TDIA, apart from its detectors for solar, X and γ rays, as well as celestial X and γ rays and primary cosmic rays, has two ultraviolet telescopes aboard for high resolution stellar spectroscopy and celestial scanning.

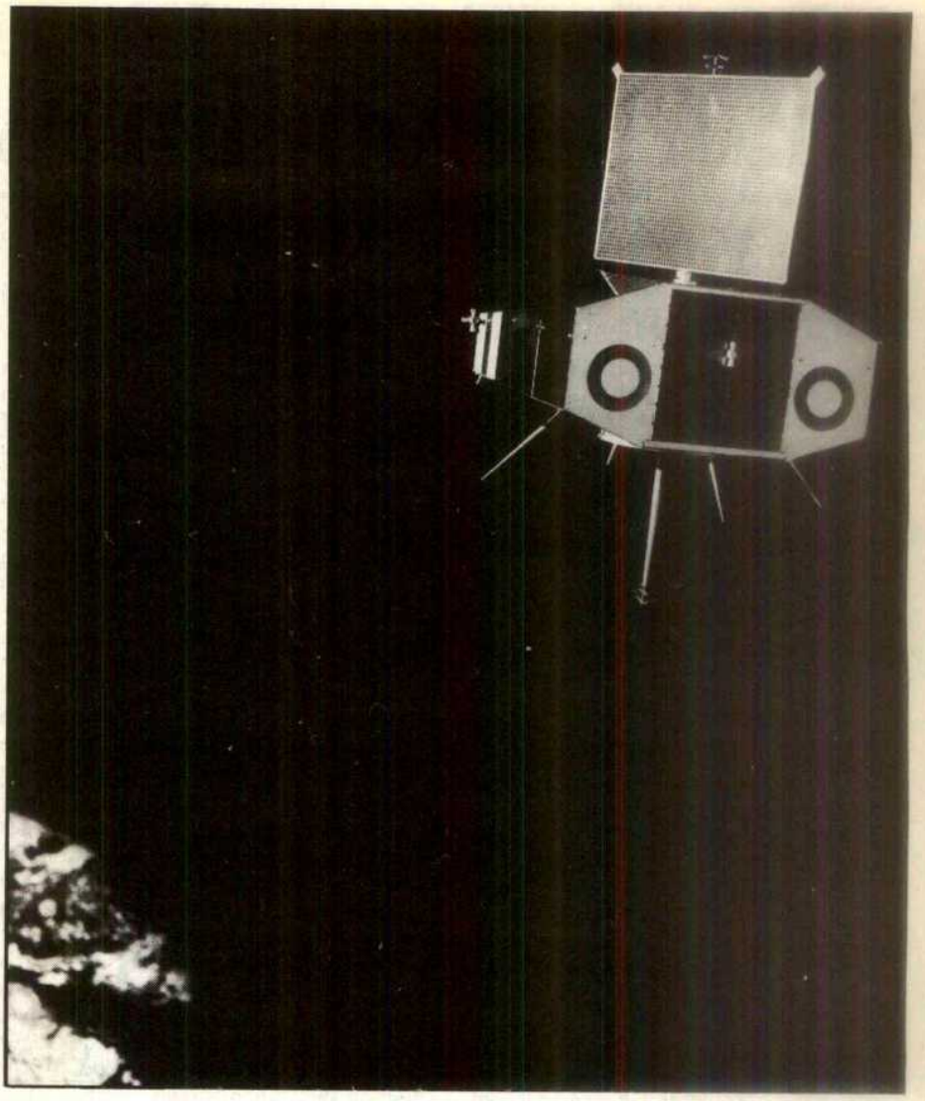


The development programme at present being carried out and the one planned for the near future include sophisticated missions which will pursue the exploration of the Earth's environment with investigation of the magnetosphere, using the GEOS spacecraft (a geostationary satellite to be launched in 1976) and IME (International Magnetospheric Explorer to be launched in 1977 as a part of a three-spacecraft collaborative mission with NASA).

Both will measure typical magnetospheric parameters but GEOS is characterised by its extremely high data flow and advanced experimental techniques; IME together with the other NASA spacecraft will provide a tool for a synoptic study of the magnetosphere where spatial variation of local parameters is separated from the temporal one.

In the field of astronomy the European community of astronomers is to participate in the joint United Kingdom/NASA IUE (International Ultraviolet Explorer) geostationary mission which is to carry a high resolution ultraviolet telescope and spectrometer to which the European scientists will have access through a Data Acquisition ground facility in Spain. Also in astronomy, but this time not ultraviolet, are the ESRO missions COS-B, carrying a γ-ray telescope and EXOSAT carrying an X-ray telescope; the latter mission will no doubt bring X-ray astronomy a step further, thanks to the excellent angular resolution that can be obtained by using lunar occultation.

Looking to the still more distant future, the scientists are now studying missions of various kinds and one of the dilemmas they will eventually face is brought about by the development of Spacelab. This facility will have features distinctly different from those the scientists have been used to in previous missions: the substantially larger payload capability will enable them to accommodate large instruments and crew but the orbital limitations will make *in situ* magnetospheric measurements beyond, say, 1,000 km altitude impossible. Furthermore the duration of missions will be limited but repetition of them will probably be quite frequent, and man's presence aboard will make the missions more flexible. The requirement for long period monitoring will no doubt remain and automatic satellites in many fields of research will complement the measurements on board Spacelab.



OTS: orbital test satellite

Astronomy remains one of the main areas of interest with continuing investigations in the ultraviolet, X-ray and γ-ray regions of the spectrum and extensions into the infrared.

Future missions being studied aim at infrared observations using either automatic satellites for sky surveys, or a larger Spacelab-borne telescope with good pointing accuracy for measurement of emission and absorption lines. Furthermore advanced missions in ultraviolet and X-ray celestial spectroscopy are envisaged, mainly using Spacelab. Solar physics with high spectral and spatial resolution remains at the centre of interest, using both Spacelab-borne telescopes and automatic satellites, depending whether the misison objective is a detailed, high resolution study of phenomena that cannot be observed from the ground or continuous monitoring of the solar disk. Also a Spacelab-borne facility for magnetospheric, ionospheric and atmospheric research is being considered, as well as automatic satellites for measurements of fields and particles out of the ecliptic plane or far out in the Solar System.

Since 1971 ESRO activities have also been oriented towards space applications on which heavy emphasis has been placed. The Meteosat programme is to be Europe's contribution to the space element of the Global Atmospheric Research Project (GARP) which will be carried out in 1976 and 1977 prior to establishing a worldwide system to be part of the World Weather Watch (WWW). The geostationary Meteosat project will carry a radiometer to provide good resolution photographs of the Earth in the visible and infrared. As from late 1973 the project has been in the development stage and the satellite will be launched at the end of 1976.

EXOSAT : highly eccentric orbit satellite to be launched in 1979, carrying an X-ray telescope in the 0.1–20 keV range, using lunar occultations for high resolution determination of X-ray sources.

A geostationary satellite, the Orbital Test Satellite (OTS), is under development for telecommunications, experiments and pre-operational use, its beam covering western Europe and the Mediterranean. It is to be a precursor of an operational communications satellite system to satisfy the needs of the European Postal and Telecommunications Services in the early 1980s, some four years after the launching of OTS in early 1977.

The increased air-traffic density over nonpopulated areas and the inadequate high frequency communications now used for aircraft over such areas give rise to an obvious application of satellites for air traffic control. Aerosat a collaborative venture of ESRO and the United States aims at establishing a pre-operational system of geostationary satellites, in the first instance over the Atlantic.

Marots, the latest newcomer to the family of ESRO's applications missions, is another example of space technology's potential for communications. The spacecraft technology being developed for OTS is perfectly suitable for maritime communications. The beam of the geostationary satellite will cover a large part of the hemisphere centred on the Greenwich meridian. The spacecraft is going to be launched in mid-1977, about six months after the launching of OTS.

Two other new projects recently included in the ESRO programme are Spacelab and Ariane. The United States shuttle programme, now going ahead at full speed, will permit the placing into orbits of several hundred kilometres altitude of an aircraft-like vehicle roughly the size of the present DC9. The vehicle is recovered at the end of each mission as well as many elements of the associated boosters used for launching. The 'Sortie Module', or as it is now called 'Spacelab' (a fully equipped modular laboratory placed into the vehicle) is being developed by ESRO as part of a collaborative programme with NASA. Spacelab can consist of a combination of modular elements, assembled to either a cylindrical container some 6.5 m long and 4.5 m in diameter, or to other configurations consisting of a smaller Spacelab capsule and external pallets on which experimental equipment, such as astronomical telescopes and other sensors, can be mounted. The large volume available for experiments operated and maintained by humans, the large weight-carrying capability and the power available—all combined with a shirt-sleeve environment, with data processing and other facilities aboard—destine Spacelab to become by early 1980 the most flexible tool for space experimentation and space operations ever built.

The missing element in Europe's space capability has always been heavy launchers. The Ariane launcher (originally the French L3S, now Europeanised) is to fill the gap. A three-stage vehicle, using high energy propulsion in its third stage, will be able to place 750 kg into geostationary orbit when launched from the Kourou range in French Guiana. Four test launches are foreseen between the beginning of 1979 and mid-1980.

The almost simultaneous start of all the programmes described above, and thus the concentration of launches in 1976 and 1977, will put a strain in the next two to three years on Europe's resources devoted to space. In spite of this the interest for other space programmes remains, and several other applications are being actively studied. Data transmission from a satellite seems to offer interesting advantages and television broadcasting seems to be another obvious candidate for space application. The United States' experience in experimental surveys of Earth resources indicates that this application may be one of the more important ones in the future. ESRO is also studying the possibility of such missions.

Recently a possibility of determining, with extremely high accuracy, the position of radio emitters on the ground, on the sea or in the air (using orbiting satellites) attracted attention and a French proposal to undertake a project called Geole is being discussed. The proposal is to use such techniques for cartography, glaciology and also for mineral prospecting and exploitation.

This list is by no means exhaustive and it has been the experience of all those involved in space research that new applications are constantly being found. Space research is only 17 years old—the first Earth satellite was in 1957. It is only in the 1980s that humanity will fully make use of this new and promising field.

international news

Mr. Varley reports on North Sea energy

Eleanor Lawrence

ALL set fair on the energy front was the message that the Secretary of State for Energy, Mr Eric Varley, delivered in his annual report to Parliament on the state of Britain's oil and gas reserves (*Production and reserves of oil and gas in the United Kingdom: a report to Parliament by the Secretary of State for Energy*, HMSO, 32p).

Assuming the forecasts are correct, Britain should be self sufficient in oil by 1980. At present, consumption of oil in the United Kingdom runs at around 100 million tons a year and is exepected to rise in the next 10 years. Oil production could well reach 100–140 million tons a year by 1980 and be sustained at this rate throughout the decade, says the report. Although present proven commercial reserves could not keep this sort of production up, it is confidently expected that further commercial finds will be made in areas already licensed in the North Sea, the Celtic Sea and areas that will be explored when licences are granted. Indeed, as Mr Varley was introducing the report Occidental Oil announced a new find, the Claymore Field near its Piper Field off the Orkneys.

But the estimates for the first oil ashore in 1975 have been downgraded from 25 million tons (last year's estimate) to 5 million tons. This setback is due to delays in obtaining and installing pipeline and production equipment as a result of materials and labour prolems.

On the thorny problem of finding building sites for the massive production platforms, Mr Varley said that he had no plans in hand to bring in legislation. At present the industry is not unduly worried about a shortage of platform building sites, but Mr Varley warned that his department would not hesitate to ask for legislation to speed up present planning procedures if it became necessary.

The first oil ashore is expected to come from the big Forties field controlled by BP. This is now expected to start production in 1975 after delays in installing steel production platforms that were supposed to have been in position in 1973.

Estimated reserves of oil in the North Sea now total 895 million tons from proven sources with a possible total of 2,950 million tons when all possible sources already discovered are taken into account. These figures compare very favourably with last year's estimate of 70–100 million tons with reserves of 800–1,300 million tons to be proved to sustain the forecast production level. The report stresses the difficulties in giving accurate estimates of production levels and reserves, especially as no oil has actually come ashore yet. More realistic figures should be available when the fields have been operating for a few years.

In contrast to oil, the North Sea gas industry has now been in operation for several years. Reserves remaining are estimated to be sufficient to provide between 5,000 and 6,000 million cubic feet a day, about double last year's consumption, in the late 1970s. This rate of production could be sustained with existing reserves until the 1980s but unless new reserves are found production will then slowly decline. Exploration for new reserves is now being concentrated in parts of the North Sea other than the heavily developed area off the south-east coast of England and the northern basin, which includes the Frigg field, and seems extremely promising.

Commenting on the report, Mr Varley said that Britain was better placed for energy in the medium term than many other industrial countries. In the 1980s some crude oil of the heavier grades would have to be imported for certain purposes such as the manufacture of lubricants but otherwise Britain would probably be physically self sufficient for oil. When asked if he planned any further controls to prevent oil companies sending the oil abroad, he said that present regulations ensured that all oil from the North Sea would be landed in Britain and that present export licensing arrangements would be sufficient controls. Self sufficiency in oil means, however, that a great deal of the oil from the North Sea will have to end up as domestic and industrial fuel given current consumption in the United Kingdom. Some people are of the opinion that the high quality North Sea oil is too valuable to burn and that Britain would get better value from her oil if it were chanelled into the manufacture of petrochemicals for export.

Although he regards the turn of Britain's energy fortune as very encouraging, Mr Varley tempered the general air of euphoria with a warning that the oil and gas reserves will not last for ever and that the best possible use must be made of them. To these ends he committed his department to investigating ways of conserving energy although he conceded that this would be extremely difficult to do for the domestic consumer.

Test ban talks draw liberal fire

Colin Norman, Washington

THE recent announcement that the United States and the Soviet Union are trying to negotiate an agreement which will limit the size of underground nuclear explosions (but not ban them entirely) has drawn fire from the Federation of American Scientists (FAS), an intellectually heavyweight organisation which lobbies chiefly for arms control, and from a handful of liberal senators. The federation has warned that such a treaty would probably have little effect on the development of new nuclear weapons and that it would have no effect on nuclear proliferation.

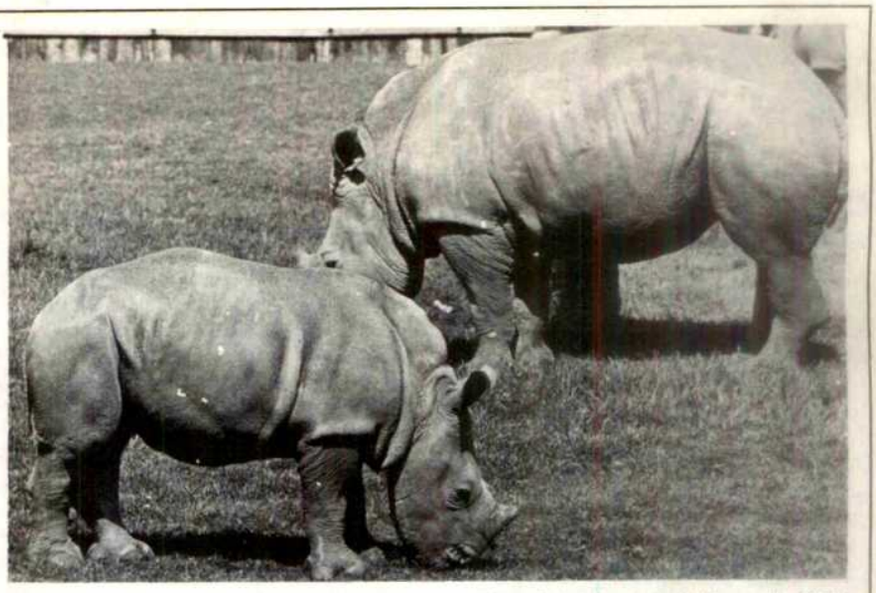
The fact that a so-called threshold treaty is under discussion surfaced earlier this month, before India joined the nuclear club, and it is generally believed that some form of agreement will be ready for President Nixon to sign when he travels to Moscow for a summit meeting at the end of June. It is cynically being viewed in Washington as a device which will allow Nixon to maintain his self-proclaimed image as a peacemaker even though he will be unlikely to bring back from Moscow any major new arms limitation agreement resulting from the strategic arms limitation talks.

A threshold test ban treaty is likely to set a limit on the magnitude of seismic signals which can be sent out by an underground nuclear explosion. In other words, it will enable both the United States and the Soviet Union to carry on testing small nuclear devices provided that they do not send out seismic signals greater than whatever threshold is negotiated.

An FAS statement, released at a press conference last week and endorsed by five former US disarmament negotiators, argued that unless the threshold is set at a very low level it is unlikely that the number of tests will be reduced below their present level. This is particularly true since two major weapons programmes —the developement in the United States of small, low yield tactical nuclear explosives and the building in the USSR of new and improved MIRV warheads—require tests which will probably be below the threshold.

As Dr James Leonard, the US ambassador to the Geneva disarmament negotiations between 1969 and 1971 and now a Vice President of the United Nations Association, put it at the press conference, "A threshold treaty is a reflection of the philosophy that the United States needs to keep testing".

The FAS also emphasised the difficulties that would be involved in making sure that a threshold treaty is not violated. Since the seismic signals sent out by an underground explosion would not necessarily be of the same magnitude at all instrumentation stations, an explosion which in fact is below the threshold could register as being above it. "Thus, not only will the negotiation of an international verification system be extremely difficult", the statement says, "but even with the best of intentions suspicions of cheating are likely to arise".



Another serious reservation expressed by the FAS is that a threshold treaty would do little to halt the spread of nuclear weapons—a topic which has suddenly been thrust into the foreground with the announcement of India's first successful nuclear test on May 18. Leonard, for example, suggested that such a treaty "would be seen by others in the world not as a serious disarmament measure but as a sham—a fraud by the United States to protect its right to test". He added that "it would not only be seen that way, it would be used that way".

Since many non-nuclear nations have refused to sign the nuclear non-proliferation treaty unless the super powers limit their development of nuclear weapons, a threshold treaty which allows continued testing would do little to improve the prospects for halting proliferation. Similar sentiments were also expressed last week by Senator Edward M. Kennedy, who warned that a threshold treaty "would be seen by many nations . . . as continued hypocrisy by the super powers".

Kennedy, who has recently returned from a trip to the Soviet Union reports that he is convinced that the time is now ripe to press ahead with negotiations for a comprehensive test ban. He said that from his "discussions with Soviet leaders, I believe that they would be willing to move forward in this area".

Backed by 36 co-sponsors, Kennedy last year introduced into the Senate a resolution calling on the United States and the Soviet Union to seek an immediate moratorium on nuclear testing and to begin serious negotiations toward a comprehensive test ban. That resolution will be on the floor of the Senate in the next couple of weeks and if it is passed it will send a clear signal to the Administration. Since the Senate will have to ratify whatever treaty is negotiated, if it insists on a comprehensive treaty by passing Kennedy's resolution intact according to some observers, it could have one of two effects. Either the Administration will try to negotiate a treaty with as low a threshold as possible, or the hand of those within the Administration who have argued for a comprehensive ban will be strengthened to such an extent that the negotiations will be aimed not at a threshold but at a complete test ban.

One concern voiced both by Kennedy and the FAS is that negotiation of a threshold treaty could forestall completely the achievement of a comprehensive ban. As the FAS statement put it, "We understand very well that the politics of summitry and the politics of impeachment both impel the Administration towards an arms control agreement in June in Moscow but we do not want to see an important element in our national security—the complete test ban—sold out in favour of a much less useful agreement".

White rhino born at Whipsnade, 1973.

DESPITE fears that the higher entrance charges as a result of the introduction of Value Added Tax would discourage visitors, both London Zoo and Whipsnade had even higher attendances last year and finished 1973 in surplus. For the first time since 1968 more than two million people visited the London Zoo in 1973, spending a total of £1 million. Introducing the Annual Report, the Secretary of the Zoological Society, Lord Zuckerman, said that the high attendance, in the absence of an outstanding animal event or the opening of any major building, reflected the very high standard of 'normality' at the Zoo. The cost of the research and educational programmes that the society maintains amounted to more than £0.5 million in 1973. The two research institutes in the society's grounds, the Nuffield Institute of Comparative Medicine and the Wellcome Institute of Physiology cost £189,000 and £49,000, respectively, to run last year and of this the society directly contributed £183,600 from its income from such sources as entrance fees. Throughout the report, the theme of the rôle of the zoo in conservation is apparent. Births in captivity of rare or endangered animals such as white rhinos, cheetahs and orang-utans are given prominence, and this function of the present-day zoo is picked up in another of the society's publications, the *International Zoological Yearbook*, which for the first time has a special section devoted to the ethical and practical problems of trading in and rearing rare wild animals. Geoffrey Schomberg, the Secretary of the Federation of Zoological Gardens of Great Britain and Ireland, writing in the Yearbook asks: "Are endangered species a proper object of retail trade in any circumstances?" Too many zoos, he says, while paying lip service to the ideals of conservation become fiercely competitive in acquiring rare specimens.

Pentagon admits Vietnam rainmaking

Colin Norman, Washington

AFTER years of secrecy, evasion and even outright denials, the Department of Defence has at last admitted that it carried out an extensive weather modification programme during the Vietnam War. The operation, which took place between March 1967 and July 1972, was designed to increase rainfall over the Ho Chi Minh Trail and make it difficult for the North Vietnamese to move troops and equipment into South Vietnam along muddy roads and jungle trails.

The Pentagon's admission came during top secret hearings held by a Senate subcommittee, on March 20, a transcript of which was made public last week. The transcript reveals that the rainmaking operations were so highly classified that even some senior Pentagon officials were unaware of them, and that there is now a deep division of opinion within the Department of Defence about their effectiveness.

According to testimony given at the hearings by Lieutenant Colonel Ed Soyster, a total of 2,602 cloud seeding missions were flown over Laos, Cambodia and North and South Vietnam, and 47,409 cannisters of silver and lead iodide were expended during the five-year programme. The objective was to supplement natural rainfall during the normal rainy season, and to extend its length, thereby causing landslides, washing out bridges and generally turning trails into a sea of mud.

Although it has been rumoured and reported in newspapers for about three years that the United States indulged in rainmaking operations during the Vietnam War, the extent of the programme revealed during the Senate hearings has surprised many observers.

The operations resulted from an extensive test carried out in October 1966 in Laos. According to Soyster's testimony, 56 cloud seedings were conducted, with a success rate of more than 85%, and the Commander in Chief of Pacific Operations concluded that rainmaking over the Ho Chi Minh Trail "could be used as a valuable tactical weapon". Operational cloud seeding missions began on March 20 the following year.

An air force base in Thailand was used for the operation which was carried out with weather reconnaissance aircraft. In short, cloud seeding consists of dropping burning photoflash-type cannisters into an updraft in a cloud mass. As the cannisters burn, silver iodide or lead iodide is produced and this acts as a seeding agent, causing drops of moisture to form in the cloud, which eventually fall as rain. The entire military rainmaking operation cost about $3.6 million a year.

Initially, the area chosen for cloud seeding consisted of South-eastern Laos and a small area of North Vietnam, but later in 1967, operations were extended into North Vietnam and a small region of South Vietnam. Finally, in 1972, portions of Cambodia and a larger region of South Vietnam were included.

All cloud seeding activities over North Vietnam were, however, halted on November 1, 1968, the day that President Lyndon Johnson ordered a bombing halt, and they were never reinstated. And the entire operation was ended on July 5, 1972—just two days after the *New York Times* published a lengthy account of the Pentagon's rainmaking activities.

Soyster told the committee that although it was usually possible to seed every cloud within a target area, priority was given to seeding clouds directly over roads, intersections and river crossings, which indicates an accuracy for the operation far greater than many independent observers believe possible.

How successful was the programme? According to Soyster, the Defence Intelligence Agency calculated that "rainfall was increased in limited areas up to 30% above that predicted for the existing conditions". He added that sensor recordings of movement along the Ho Chi Minh Trail "indicated enemy difficulties from heavy rainfall", and said that in April 1971 there were about 9,000 enemy logistic movers in Laos each week, but by the end of June the number had dropped to 900. The greatest decreases in troop movements came during the first week in June, when a typhoon struck the area, and during the third week in June, when the Pentagon's rainmaking activities were at their height.

The Pentagon's admission that it has indulged in weather modification came after persistent attempts by Senator Claiborne Pell, a Rhode Island Democrat, to get at the facts. Pell, who is Chairman of the Subcommittee on Oceans and International Environment of the Senate Foreign Relations Committee, proposed a resolution which the Senate passed last year by a vote of 82 to 10 calling on the United States Government to launch international negotiations aimed at banning weather modification as an instrument of war, and it was his subcommittee which held the top secret hearings on the military rainmaking operations. The transcript of those hearings was declassified by Secretary of Defence James Schlesinger.

Details of the rainmaking operations were held in strict secrecy, presumably because of the sensitivity of the programme. According to Soyster, individual mission reports were transmitted through special communication channels to the joint chiefs of staff, who made periodic reports to the Secretary of Defence and the White House.

Furthermore, since reports and rumours of the operation appeared in the press, the Pentagon has been more than evasive on the matter. During hearings held by the Senate Foreign Relations Committee in April 1972 for example, then Defence Secretary Melvin Laird was asked whether the military had ever indulged in rainmaking activities. He replied: "We have never engaged in that type of activity over North Vietnam", but in January this year he wrote to the committee to apologise for his mis-statement, saying that he was unaware of the weather modification operations carried out over North Vietnam by the Johnson Administration. He was, of course, fully aware of the rainmaking activities he had authorised over Laos, Cambodia and South Vietnam, but simply evaded any mention of them.

The Pentagon's obsession with the secrecy of the programme was taken to its final extreme in 1972, when it refused even to supply details of the operation to an interagency task force chaired by Herman Pollack, director of the bureau of international scientific affairs in the Department of State, which was trying to develop administration policies on both military and civilian weather modification. Although that study itself was classified, the Pentagon has now admitted that the rainmaking operations were so heavily classified that it refused to turn over any information to Pollack.

Since the skies over South-east Asia were raining high explosives and all manner of unsavoury weapons during the Vietnam war, why did the Department of Defence choose to hide the fact that it was tinkering with the weather? One reason is that the whole area of weather modification is a sensitive one simply because it is a new area of warfare which may eventually open up some frightening possibilities.

As Pell puts it, "We should not open the Pandora's box of harnessing nature, of changing the weather or developing techniques to create typhoons or earthquakes with devastating effects upon foes and neutrals alike. I believe this new kind of weaponry should be eschewed by developed, so-called civilised nations".

Club of Rome associations

David Spurgeon, Ottawa

CANADA is the latest country to have formed a national association inspired by the Club of Rome. The decision was made at a meeting in Toronto early in May, and the venture has the backing of an impressive array of government and business officials.

The association's objects are "to promote study and discussion among all segments of the Canadian public of the nature of world problems and the need to develop new policies, attitudes and courses of action to ensure a stable and viable future for mankind . . . " More specifically, it will attempt to identify Canada's role in the solution of world problems, and the implications for Canada of possible world solutions.

Both the co-founders of the Club of Rome, Dr Aurelio Peccei of Italy and Dr Alexander King, who until recently was with the OECD in Paris, attended the Toronto meeting, which was opened with a welcoming letter from Canada's Prime Minister, Pierre Trudeau. From their accounts it was apparent that the club—largely through the impact of the MIT study it sponsored, *The Limits of Growth*—had made considerable progress in directing attention to world problems since its inception in 1968.

One reason for thinking so, as suggested by Dr Peccei, is the establishment of a series of United Nations Conferences for discussion of world problems such as population, food, energy and materials. Another is the organisation in many nations of groups like the Club of Rome.

As described by Dr King, these included a whole diversity of approaches. The first was set up in Holland, which according to King is not surprising, because of its twin problems of dense population and heavy industrialisation. The Dutch association is a group of private people gathered in a nonparty organisation.

The second—also not surprisingly, for the same reasons—was organised in Japan, on a different basis, backed by and formed as a committee of the techno-economic society. Groups in other countries include some not connected with the Club of Rome but interested in similar problems (for example, Great Britain and Austria), and luncheon clubs and groups of engineers or teachers in France, Denmark, Belgium and Sweden.

Finland has formed a more formal study group to determine what the role should be of a small, progressive country in the modern world; Switzerland, with four Club members, invited four government members to discuss Club of Rome thinking and found them receptive to the points where they decided that both the traditional political organisation and neutrality of the country was obsolete.

But Dr King found some of the keenest interest in an unexpected place: South Africa. I was in South Africa recently, he said, "and, much to my surprise, found the Club of Rome better known in that country than in any other." Some citizens there have formed an independent information group who just meet and talk.

The Canadian Association for the Club of Rome has applied for a charter as a corporation without share capital. Its first directors include the president of the pulp and paper industry's research institute, Dr Pierre R. Gendron; Senator Maurice Lamontagne, whose senate committee carried out one of the most comprehensive studies of national science policy yet made; a retired oil company executive, Mr Ronald Ritchie; the president of the Ontario Research Foundation, Dr William Stadelman; the former Chief Science Adviser to the Federal Cabinet, now Dean of Applied Sciences at Queen's University, Dr Robert J. Uffen; and a senior civil servant with many years experience in Canadian Science policy, Dr J. Rennie Whitehead.

BENEATH the elegant tapestries of the Schlosshotel, Kronberg, Germany a small group of biologists, philosophers and psychiatrists gathered recently to constitute the Boehringer Ingelheim Symposium on the Creative Process in Science and Medicine. Pictured above, listening to Sir John Eccles testify are, in the front row, Sir Hans Krebs, Jacques Monod, Manfred Eigen, Desmond Morris and Sir Karl Popper. What leads to some scientists being creative way above the average, and does the creativity of scientists bear any resemblance to that of artists and composers? Participants were decidedly coy about speaking other than in the abstract, despite Krebs's personal example of trying to piece together how he came to produce new ideas. All seemed agreed that breaking out from conventional thinking was a major ingredient in creativity —the agreement was so complete that it must qualify as conventional thinking and therefore . . . Monod discussed 'subjective simulation'—a process almost of putting yourself in the position of the electron or whatever that you are thinking about. The debt of many participants to Popper was clearly great—an interesting contrast with the world of physical science where one's impression is that there is less understanding of what he is about. Desmond Morris had probably the nicest story to tell—A journalist once asked Picasso: What is creativity? 'I don't know, and if I did I wouldn't tell you.'

correspondence

Canadian science

SIR,—In your issue of March 15, David Spurgeon offered his own interpretation of recently announced changes in the structure of federal scientific activities. After reading his article, I cannot avoid feeling that the author has done a disservice to Canadian scientists.

Spurgeon makes the statement that the press releases of the Ministry of State for Science and Technology served only to confuse in an attempt to provide more detail about the rather general statements made in the throne speech. I submit that he is guilty of that particular offence.

"The question in the minds of some", wrote Spurgeon, "was whether the ministry was finally becoming . . . an all-powerful, monolithic instrument of power in Canadian science policy". He went on to say that a quick sampling of reaction in the science community indicated that the ministry's releases had indeed given this impression. The sample must have been a very quick one because, following the release of the information kit, a survey of Canadian scientific opinion published in the daily press indicated that most of those surveyed were not prepared to condemn the changes out of hand but instead would wait for specific actions before passing judgment.

Spurgeon cites, as perhaps the most confusing element of the announcement, the failure of the ministry to mention anything about possible new reporting relationships for the granting councils. Surely Spurgeon is hung up on the administrative considerations he so vigorously condemns. Reporting relationships are simply provisions for accountability to Parliament. What is important to every scientist are factors such as peer assessment of research proposals, the allocation of funds to the granting councils and the input of the granting councils to the Inter-Council Coordinating Committee. All these factors were clearly dealt with in the ministry press releases. The reporting channels for the existing granting councils have not been altered.

Finally, Spurgeon questions the separation of the granting function of the National Research Council of Canada from the laboratory function. Such a separation, he says, will destroy a vital link between government research and industry. The changes proposed for the NRC affect only the university granting mechanisms. The traditional liaison between the NRC and industry will continue.

Yours faithfully,

AURELE BEAULNES

Ministry of State, Science and Technology,
Ottawa

Journals jungle

SIR,—I am writing in reference to the article "Science Journals in a Prices Jungle," which appeared in the *Nature* dated February 15, 1974. That article discussed price rises of a variety of journals and listed "a record-breaking increase" for *International Pharmaceutical Abstracts* of "261%". I must respond to this kind of reporting since not all the information was included; this makes the information that does appear misleading.

Prior to January, 1973, *IPA* had two subscription prices—an institutional subscription price of $100.00 a year and a subscription price to individuals of $40.00 a year. A two-subscription price system was difficult to administer since many people who should have paid $100.00 were paying only $40.00, and so on. We were faced with having to increase both rates since we were losing money in the situation that existed at that time. The expense of publishing *IPA* was increasing each year and that just could not be balanced by income at existing subscription rates. After a thorough study of our subscribers, we decided to change to one institutional subscription price of $150.00 a year. The increase was from $100.00 to $150.00 and not quite as record breaking as the article implied. We felt, however, that we could not ignore the individual completely and therefore decided to offer an additional copy subscription rate of $30.00 a year (if one subscription exists at the $150.00 rate, as many additional copies as desired can be obtained at the $30.00 rate).

Other facts relating to the change are that we improved and expanded the services offered. All our promotional pieces and literature at that time mentioned that we would be providing greater coverage, most abstracts, and that *IPA* would be more current. This in fact has happened, and in 1973 we published 13% more abstracts than we did in 1972 and *IPA* was on time. We did follow through on our promises of additional services for the change in subscription price—it was not just a price change for the same service. One other fact that seems to have been completely overlooked is that *IPA* is still one of the lower priced secondary publications. Most abstracting-indexing publications are far more than $150.00 a year. Possibly our real problem is that we began at too low a subscription price for *IPA* when it began.

Yours faithfully,

DWIGHT R. TOUSIGNAUT

American Society of Hospital Pharmacists,

Washington DC 20014

Kidney transplants

SIR,—Why publish such a rank piece of scientific journalism as "Transplants: the failing machinery" (April 19, 1974)? The subject has always been an emotive one, but this is not an excuse for the lack of reason displayed and the dramatic aura with which the article is surrounded. To use comparisons between kidneys received from and contributed to the national donor pool as an indication of "reluctance . . . to share out kidneys which are not suitable for their own patients" is nonsense unless some measure of the kidneys potentially available within an institution by comparison with the size of its recipient pool is also given. Both St Mary's and Hammersmith are hospitals with a large transplant programme in areas where irremediable cranial trauma is rare. Further St Mary's does not have a neurosurgical service so that we see few patients with intracranial vascular accidents and such patients as we have with progressive primary intracranial malignant disease usually go elsewhere before they die. So we shall always be debtors rather than creditors.

Is there unequivocal evidence that "lack of understanding and cooperation between doctors . . . is largely to blame"? Of course, being human, we are too lazy, too hidebound and too hardworked always to do the right thing in complicated situations, but I do not know of data to suggest that a large number of kidneys are being lost through medical indifference.

Yours faithfully,

H. A. F. DUDLEY

St Mary's Hospital,
London W2

Super-rotation of the upper atmosphere

OBSERVATIONS of small changes in the orbital inclinations of artificial satellites have shown that the Earth's upper atmosphere (at altitudes of 150–400 km) is rotating about 20–30% faster than the Earth itself. This phenomena has become known as super-rotation. Even though it was discovered by King-Hele in the early 1960s, the cause of this 100 m s^{-1} west to east wind is still a subject of considerable debate. The change in inclination because of super-rotation is only about 0.1° during the satellite lifetime, and so spatial variations and short term effects are very difficult to detect. No clear evidence has been found of year to year variations, such as might be caused by the 11-yr-periodicity in solar activity, but over daily periods the wind seems to maximise between 2100 and 2400 local time.

Possible causes of super-rotation are:

- Horizontal pressure gradients may be set up in the atmosphere as a result of thermospheric heating by solar ionising radiation, and bombardment by energetic particles. The resulting global pressure distribution produces geostrophic and cross-isobaric winds which are probably controlled by ion drag (the motion of the F region ions borne along by the neutral winds is strongly effected by the geomagnetic field). A problem with this theory is that heating of the auroral zone, which takes place during magnetic disturbances, can reverse the mean meridional pressure gradient. This would cause a drastic change in the super-rotation, a change which has not been observed.
- Super-rotation might be caused by ionospheric or magnetospheric motions which couple with the neutral atmosphere by collision processes. Meridional electric fields can move F region ions quite efficiently even in the presence of the geomagnetic field. An average field directed towards the equator could produce the super-rotation, and these fields have been observed in high northern latitudes during negative magnetic bays. The effect should, however, be enhanced during magnetic disturbances. This is contrary to observations.
- The moving flame effect. A heat source acting on a fluid produces convective motion. If the heat source moves (as, for example, the Sun does in a westerly direction with respect to the Earth's atmosphere) the convective cells tilt, producing horizontal and vertical motions which interact to produce a mean horizontal flow. The flow rate is a function of the frequency of the heating function, and of the ratio of the kinematic viscosity and thermal diffusivity of the fluid. Permissible values of such parameters in the case of the Earth's atmosphere unfortunately yield inappreciable amounts of super-rotation; a situation which compares unfavourably with the case of Venus where the upper atmosphere rotates 50–60 times faster than the planet mainly because the heating function has a period of 240 days (the Venusian surface rotation period) as opposed to 1 day on Earth.
- Atmospheric waves may impart momentum to the F region, in which they are dissipated. If transmission efficiency depends on the direction of wave propagation, a net motion can be produced. As wave velocity is an inverse function of density, an imperceptible mean velocity at low levels can produce the observed thermospheric velocity.
- The Scott effect may produce super-rotation: a small brass cylinder suspended in a cylindrical vessel containing a low pressure gas, experiences a torque when a vertical magnetic field is applied, and if a temperature gradient is set up between the cylinder and the vessel. This effect might act on the atmosphere.

At present it seems that none of these theories can explain the phenomena of super-rotation completely. A sixth theory has now been put forward by Ved Mitra (Physics Department, MNR Engineering College, Allahabad, India) in a recent edition of *Planetary and Space Science* (**22**, 559; 1974). In this case, super-rotation is caused by meteoroid deposition. The meteoroids, small interplanetary dust particles which mainly originate from decaying comets, and which move in elliptical orbits around the Sun, carry, on average, a greater amount of angular momentum than that corresponding to the Earth's orbit. When they interact with the Earth's atmosphere the angular momentum must be conserved and therefore the excess orbital angular momentum of the meteoroids becomes manifest as extra spin angular momentum in the atmospheric layers in which they are arrested.

Mitra assumes firstly that the majority of the mass deposited in the atmosphere is in the form of particles with masses 10^{-6}–10^{-3}g. These meteoroids are assumed to have orbits similar to those of the larger meteors which were recorded photographically by super-Schmidt cameras during the Harvard photographic meteor project. The orbits are, in the main, within Jupiter's orbit, with low inclinations, and high eccentricities and direct motion. When these particles collide with the Earth's atmosphere they cause it to 'spin up'.

For example, particles coming from behind the Earth will be accelerated by gravitational attraction, and this increase in velocity will cause them to move away from the Sun and collide with the Earth from outside, giving it a prograde spin. Particles in front of the Earth, in direct orbits, will lose velocity because of gravitational attraction, strike the Earth on the Sunward side and again impart prograde spin. This increase in spin during gravitational accretion is exactly the same process propounded by Alfvén for the origin of planetary rotation in the Solar System.

Mitra calculates the orbital angular momentum per unit mass for the incident meteoroids, and by comparing this with the angular momentum of the Earth finds the influx required to produce the observed super-rotation of 100 m s^{-1} in the atmospheric layers above 150 km. The answer comes to 34 tons a day, a value in excellent agreement with that of 43.5 tons a day obtained by Whipple (*Smithson. Astrophys Inst. Prepr.*, No. 239; 1967), who, however, considered the Earth as a nongravitating sphere; 55 tons a day by Dohnanyi (*Icarus*, **17**, 1; 1972) who used results of satellite-borne penetration experiments, and ground-based visual and radar observations; and 48 tons a day obtained by Zook *et al.* (*Planet. Space Sci.*, **18**, 953; 1970) obtained from observations of micrometeoroid impact on the window of Gemini spacecraft.

Unfortunately, there are two problems with Mitra's argument. The first is minor and concerns the size of

the incident particles. Recent work (for example, Hughes, *Space Res.*, **14**, 789; 1974) indicates that about 95% of the mass incident on the Earth is in the form of particles of mass 10^{-9}–10^{-5}g which have very low geocentric velocities and different orbits from those assumed by Mitra.

The second point concerns Mitra's assumption that "the effective deceleration of the velocity initially possessed by a meteoroid takes place in the 150–400 km region". This is contrary to visual and radar observations of the more massive meteoroids ($> 10^{-3}$g) which have maximum ablation at heights of about 90 km. Either it must be assumed that the super-rotation is produced by the minor amount of ablation and momentum transfer that occurs at heights above 150 km, in which case Mitra's 34 tons a day influx must be increased accordingly, or a process of momentum transfer from the lower layers where the ablation occurs to the regions of super-rotation must be invoked; similar to that propounded for the transfer of atmospheric wave energy.

It seems therefore that the cause of super-rotation still remains a mystery and that the Earth's spinning upper atmosphere is still the happy hunting ground for new theories.

DAVID W. HUGHES

The collagen triple helix

JAMES WATSON, in his Nobel address on the work which led to the Watson–Crick model for DNA, spoke of his fear that this structure might have turned out to be "dull and uninteresting, like collagen". In the event, collagen has turned out to be a most interesting protein which has occupied the attention of workers from a wide range of disciplines.

Recently, attention has been focussed on the intracellular process by which the three polypeptide subunits (α chains) of monomeric collagen form its characteristic triple-stranded helix. The very slow and incomplete *in vitro* renaturation of α chains derived from extra-cellular collagen led to the proposal by Speakman (*Nature*, **229**, 241; 1971) that the α chains as initially synthesised might have peptide extensions. It was postulated that these extensions or 'registration peptides' might serve to bring the three α chains into a conformation which would allow rapid formation of the triple helix. Subsequently much evidence has accumulated to indicate the existence of a precursor of this type (called procollagen) during the biosynthesis of collagen in a wide variety of tissues, and some of the properties of procollagen have been defined (reviewed by Schofield and Prockop, *Clin. Orthopaed. Rel. Res.*, **97**, 175; 1973). Initially considerable controversy existed about the size of these extensions and their amino acid composition, but there now seems to be general agreement that type I and type II procollagens comprise polypeptides of 120,000–125,000 daltons. Moreover, it seems that all pro- α chains contain cysteine, an amino acid not usually found in extracellular interstitial collagen, with the possible exception of a newly discovered form of collagen (type III) recently isolated from several human tissues (Chung and Miller, *Science*, **183**, 1200; 1974).

The demonstration of the presence of cysteine in procollagen suggested that disulphide bonding occurs between the pro- α chains and several groups have now reported that procollagen is secreted as a triple-stranded disulphide-stabilised molecule of molecular weight of about 360,000 daltons. Similar observations have been reported by Monson and Bornstein (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 3521; 1973) who also demonstrated that the procedures used previously in their laboratory for the extraction of procollagen from cranial bones resulted in partial cleavage of the extension peptides by endogenous proteases such that the regions containing the interchain disulphide linkages were lost. This finding reconciles several apparently conflicting reports concerning the occurrence of interchain disulphide bonds in procollagen.

The possibility of a relationship between the process of disulphide bond formation among pro-α chains and that of triple-helix formation was suggested by studies reported by Grant *et al.* (*J. biol. Chem.*, **248**, 7432; 1973) on the biosynthesis of a basement membrane collagen of embryonic chick lens. Procollagen secreted by lens cells was found to be linked by interchain disulphide bonds and in a triple helical conformation. By contrast, intracellular lens collagen was found to be in a random coil conformation, and interchain disulphide bonds between the pro-α chains were also absent. That the formation of the disulphide bonds may be of considerable importance in promoting the formation of the triple helix is also indicated by studies using pulse label and chase experiments in embryonic chick tendon cells (Schofield *et al.*, *Biochemistry*, **13**, 1801; 1974) and cartilage cells (Uitto *et al.*, *Fed. Proc.*, **33**, 617; 1974). A close correlation was observed between the extent of interchain disulphide bonding among pro-α chains and the extent to which the procollagen was in a triple-helical conformation. The rates of these processes, however, seem to vary according to the cell type and may thus influence the time taken for secretion of procollagen from different types of cells.

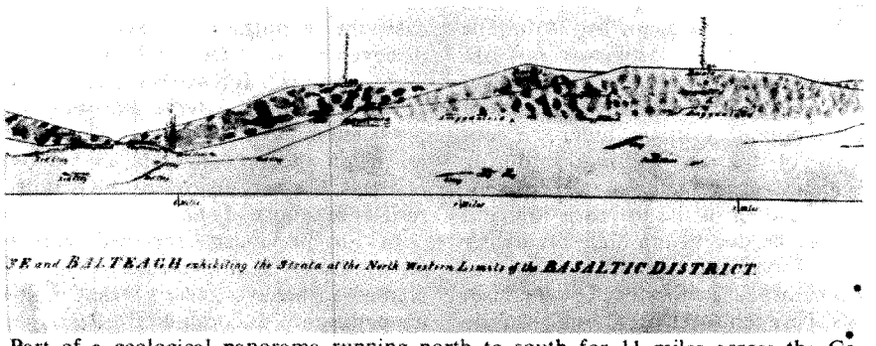
Further evidence of a role for disulphide bonds in procollagen synthesis comes from the work of Uitto and Prockop (*Biochem. biophys. Res. Commun.*, **55**, 904; 1973). Embryonic chick tendon cells were incubated at 37° C under conditions in which they synthesised and accumulated protocollagen, (unhydroxylated procollagen) which is non-helical above 24° C. When the cells were cooled to 15° C, the intracellular protocollagen, which was shown to contain interchain disulphide bonds, became triple helical within five minutes. But when disulphide bonds in the amino-terminal extensions of protocollagen were reduced by treating the cells with dithiothreitol, the rate of helix formation on cooling was markedly decreased; this suggests that the formation of interchain disulphide bonds is probably a necessary prelude to helix formation. Whether or not this process is mediated by enzymes is unknown, but in tendon cells interchain disulphide bonding of procollagen polypeptides occurs in the rough endoplasmic reticulum soon after release of the completed polypeptides from membrane-bound ribosomes (Harwood *et al.*, *Biochem. biophys. Res. Commun.*, **55**, 1188, 1973).

A further factor in considering the formation of the collagen triple helix is the part played by hydroxyproline. Uitto and Prockop using protocollagen were able to dissociate the disulphide bonding process from any influences exerted by hydroxyproline residues in the polypeptides. It is clear from studies of the denaturation temperatures of procollagen and protocollagen, however, that the absence of hydroxylated prolyl residues markedly decreases the thermal stability of the collagen triple helix (Jimenez *et al.*, *Biochem. biophys. Res. Commun.*, **52**, 106; 1973; Berg and Prockop, *ibid.*, 115). It seems therefore that the major role of hydroxyproline is to maintain the procollagen polypeptides in a triple-helical conformation under physiological conditions, and that one of the chief roles of the amino-terminal extensions is to facilitate chain association through the formation of interchain disulphide linkages leading to the formation of the triple-helical structure in a time which is biologically feasible.

D. S. JACKSON
M. E. GRANT

First official geological survey in the British Isles

from Gordon L. Davies



IN March 1832 Henry Thomas De La Beche approached the Master General and Board of Ordnance offering to plot geological lines upon the ordnance maps of south-western England, and the outcome was the establishment in 1835 of the Geological Survey of Great Britain as a branch of the Ordnance Survey. A fact which is much less well known is that as early as 1824 Lieutenant-Colonel Thomas Frederick Colby (1784–1852), the Superintendent of the Ordnance Survey, had himself inaugurated an Ordnance Geological Survey of Ireland, and although it proved abortive, it was a pioneering venture that deserves to be remembered in this the year of its hundred and fiftieth anniversary.

Colby was keenly interested in geology (he had been a member of the Geological Society of London since 1814) and he resolved to bring Irish geology within his purview when in 1824 he was directed to extend the Ordnance Survey's operations into Ireland. The Irish rocks were to receive this particular attention because the survey was under instruction to publish maps of Ireland on the lavish scale of 6 inches to the mile instead of the 1-inch scale that was standard in Britain. Colby hoped that as his men worked their way across Ireland they would also be able to collect geological information as a byproduct of their normal topographical duties. Indeed, writing in February 1826 he looked forward to the completion in Ireland of "the most minute and accurate Geological Survey ever published".

Initially Colby's plan was that the surveyors would collect geological samples, mark the collection sites on maps, and then despatch both samples and maps to the survey's Dublin headquarters where a geologist would identify the specimens and then interpolate geological lines on the maps. This seems to have been the procedure used when the survey began operations in counties Antrim and Londonderry in 1825, but the inadequacy of such random methods soon became apparent. In November 1826, therefore, Captain John Watson Pringle (who lived about 1793–1861), a Waterloo veteran and a former pupil of Friedrich Mohs at the Freiberg School of Mines, was appointed to reshape the survey's geological activities. Under his direction the field parties were themselves instructed in the construction of geological maps and sections, and for their guidance he prepared a pamphlet entitled *Geological and Mineralogical Observations* fifty copies of which were lithographed at the Tower of London in March 1827. From the surveyors Pringle expected a geological map of each parish accompanied by two geological sections drawn from north to south and east to west, and he estimated that using his methods the geological survey of Ireland would be completed by 1834 at the trifling cost of £5,500.

But Pringle's methods were never accorded a fair trial because Colby's superiors decided that geology was interfering with the survey's more legitimate topographical duties and in September 1828 Colby was directed to cease all geological investigations forthwith. He did manage to revive the Irish Survey's geological activities in January 1830 when Captain Joseph Ellison Portlock (1794–1864) took over the duties formerly discharged by Pringle, and the fruit of this resurrected geological survey was Portlock's classical map and memoir of the geology of Co. Londonderry and adjacent areas published in 1843. By then, however, the Geological Survey of Ireland was merely a poor cousin of the vigorous body that De La Beche had created in England, but this should not be allowed to obscure the significance of Colby's achievment back in the 1820s. He had in 1824 inaugurated the earliest official geological survey to operate within the United Kingdom and that only 3 years after the Corps Royal des Mines had planned in France the earliest of all national geological surveys. The French surveyors, however, did not start work in the field until 1825, the very same year as Colby's men 'broke ground' in Northern Ireland.

Sadly, Colby's abortive geological survey of 1824 never published any of its work, but a few geological maps and sections produced under Pringle's direction have recently come to light in the Dublin offices of the Irish Ordnance and Geological surveys. Some of these items have found a place in the exhibition being staged in Trinity College Dublin to mark the anniversary of the foundation of the Ordnance Survey of Ireland. The exhibition opens on June 7 and will run for 2 months.

...E and BALTEAGH exhibiting the Strata at the North Western Limits of the BASALTIC DISTRICT

Part of a geological panorama running north to south for 11 miles across the Co. Londonderry parishes of Drumachose and Balteagh. The original possesses a horizontal scale of 6 inches to 1 mile and a vertical scale of about 1 inch to 430 feet. The panorama which shows the Tertiary plateau basalts (blotched) resting upon Cretaceous chalk and Triassic sandstone, is the work of two of Pringle's officers, Lieutenants Lancey and Fenwick, and it is dated November 28, 1827. The topographical detail and geological inscriptions have been lithographed and geological colours then added by hand, and the panorama was evidently used as a specimen designed to show survey parties the type of work expected of them.

Infrared superhet for detecting pollutants

from our Chemical Physics Correspondent

ANYBODY who, since the 1930s, has built his own radio receiver is aware of the advantages of superheterodyne detection. Not merely can the main amplifier be chosen for a convenient frequency, but more importantly the signal strength is proportional to the product of the electric field strengths of the weak incoming signal and the powerful local oscillator in contrast to the less favourable square of the signal field for direct detection.

Hitherto these advantages have been denied to those who need to detect weak infrared signals, because of the lack of suitable local oscillators whose stability must be good compared with the band width of the amplifier. Stable infrared lasers have altered this position so that the whole problem of the detection of weak infrared emission is being considered. These comments are prompted by an article by Menzies and Shumate (*Science*, **184**, 570; 1974) who use the superhet principle for the detection of small amounts of pollutant gases. But as these authors point out, a wider range of applications is possible including the gathering of meterological information by sensing the atmospheric emission at selected frequencies. And it may not be long before such detection systems are used in conjunction with astronomical telescopes. Furthermore, when tunable infrared lasers are more readily available the scheme can be used in conjunction with frequency scanning.

The heart of the instrument is the mixer detector, in the present case a copper-doped germanium photoconductor. This receives the signal,

chopped with what is effectively a cold chopper, and it also receives 40 mW of power from the c.w. laser at the frequency of interest. The detector is followed by a high radiofrequency amplifier broad banded from 10 to 600 MHz, which amplifies the beat signal between the infrared sources. This device is then sensitive to radiation ± 600 MHz (± 0.02 cm^{-1}) from the laser with the exception of a narrow central gap. Providing in the absence of the emitter gas the source seems to be appropriately cold, a condition ensured in the laboratory by a cold surface beyond the back window of the sample cell, appropriate reference levels may be set and calibration provided.

The gas under study must, of course, emit at the frequency of the laser. Using a CO_2 laser at 1,109 cm^{-1} (9.02 μm) for SO_2 samples at room temperature, the emission was as little as 10^{-2} atm cm for the product of the partial pressure of SO_2 and the cell length. For ethylene at 950 cm^{-1} (10.53 μm), the figure was 5×10^{-5} atm cm in the presence of an atmosphere of nitrogen in each case. There is little doubt that these figures could be appreciably improved with tunable lasers to ensure operation at the peak of the gas line and also if the gas to be detected formed a major component of the sample so that lower pressures could be used.

Oestrogen and progesterone binding

from our Steroid Biochemistry Correspondent

IT is well established that the steroid hormones oestrogen and androgen bind to specific receptor proteins in mammalian reproductive tissues. Binding of progesterone and receptors for it, however, have been more difficult to demonstrate. In rat uterus the progesterone binding protein seems to be the same as the corticosteroid-binding globulin of rat plasma. In guinea pig uterus, however, a progesterone-binding protein (not corticosterone-binding globulin which has only a low affinity for progesterone in this species) is easier to demonstrate.

Two types of binding for oestrogens and androgens exist in the mammalian reproductive tract; one has a high affinity and a limited number of binding sites and, conversely, the other has a low affinity and an unlimited number of binding sites. Progesterone binding in the guinea pig uterus seems to follow the same pattern.

The presence of progesterone receptors has been revealed mainly by sucrose gradient centrifugation. As in the case of uterine oestrogen receptors, two components seem to exist; one has a sedimentation coefficient of 6.7S and the other has one of 4–5S. In addition to sucrose gradient centrifugation which measures directly the concentration of binding protein, binding of progesterone can be shown by simpler methods involving *in vitro* measurements of bound progesterone after removal of free hormone with adsorbents (Freifield *et al.*, *Steroids*, **23**, 93–103; 1974; Atger *et al.*, *Enclocrinology*, **94**, 161–167; 1974).

In both rats and guinea pigs these authors found that treatment with oestrogens increased the uterine binding of progesterone. In the guinea pig the increase began within 4 to 12 h and after 4 days the concentration of high-affinity binding sites per cell showed a ten-fold increase; no further increase occurred if treatment was continued for up to 2 weeks. On stopping oestrogen treatment, binding activity declined with a half life of about 3 days which suggests that the progesterone receptor is a relatively stable protein but that it is dependent on oestrogen stimulation. Further evidence for oestrogenic control of the receptor is the change in the binding protein during the oestrous cycle; the concentration of binding sites is highest at pro-oestrus when oestrogen production is high and the receptor is present mainly in the 6.7S form and lowest at dioestrus when more of the 4–5S receptor is present.

The vagina and uterine cervix of guinea pigs also contains a receptor protein which can bind progesterone. The properties of the receptor in these tissues are similar to those of the uterus although the vaginal receptor seems to be much more dependent on oestrogen than the uterine one.

This effect of oestrogen seems to be antagonised by progesterone. Administration of progesterone to oestrogen-treated castrated guinea pigs caused a rapid decline in uterine binding which reached a minimum by 6 h and which had not increased again by 24 h. The loss of binding activity was not apparently caused by a failure of labelled hormone to exchange with the endogenous bound hormone under the conditions of the test. Similarly, during pregnancy in the guinea pig, progesterone binding in the uterus is low and this may be due to the high circulating levels of progesterone.

In most circumstances synergism exists between oestrogen and progesterone and progesterone only produces a biological response in tissues which have been exposed to oestrogen. This is explainable if oestrogen stimulation is required for the synthesis of progesterone binding protein. The decreased binding activity on progesterone administration, even when oestrogen is present, might suggest that the action of progesterone is self-limiting—once a sufficiently high level of progesterone in plasma is attained, binding of the hormone in the uterus is decreased. More work is, however, required to determine these relationships.

Anomalous Kapitza resistance

from Peter V. E. McClintock Condensed Matter Correspondent

THE Kapitza resistance between liquid He II and a solid exhibits anomalous behaviour near 2 K according to a report in *Physical Review Letters* (**32**, 658; 1974) by Cheeke, Hebral, Richard and Turkington of the Centre National de la Recherche Scientifique (CNRS) at Grenoble.

When heat is passing from one solid to another one made of a different material there is always a jump in temperature across the interface which separates them. The phenomenon can be accounted for reasonably well in terms of an acoustic mismatch theory: by analogy with the partial reflection of light which occurs at an interface between two materials with different refractive indices, there is a partial reflection of the lattice waves (phonons), which constitute the flux of heat, as they try to pass between two materials in which the velocity of sound is different. The temperature discontinuity caused by this reflection of phonons is proportional to the heat flux, the constant of proportionality being known as the thermal, boundary resistance.

The velocity of sound in liquid helium is a factor of one twentieth smaller than in most solids, so that the thermal boundary resistance, between liquid helium and a solid would be expected to be particularly large. In fact, the boundary resistance, called in this case the Kapitza resistance after its discoverer, is indeed relatively very large, although, for temperatures above 1 K not nearly as large as would be predicted on the basis of the acoustic mismatch theory. There is, as yet, no really satisfactory theory of the Kapitza resistance above 1 K.

In all previously reported experiments, however, the phenomenon has seemed to behave linearly: that is, the temperature discontinuity ΔT has always been directly proportional to the heat flux Q, within experimental error. The CNRS group has measured, to a high precision, ΔT between copper or lead and liquid helium. They find that, although a plot of ΔT against Q yields an accurate straight line at small values

of Q there is, for any given temperature, a definite heat flux at which the line changes slope by up to 25%. The effect is at its largest near 2 K, gradually diminishing as the temperature is reduced.

It is now more than thirty years since the existence of the thermal boundary resistance was discovered by Kapitza (*J. Phys. U.S.S.R.*, **4**, 181; 1941) and it seems at first sight very surprising that in the course of the large body of experimental work on the phenomenon since that time, no one has reported observation of the anomalous features now being described. The effect would clearly be easily missed, however, except in cases where a large number of closely spaced data points were taken at small values of Q. Ironically, there is perhaps some evidence for the existence of these anomalies in the original graphs published by Kapitza.

As for the origin of the anomalies, the authors discuss a number of possibilities the most plausible of which concerns the onset of turbulence in the helium very close to the metal surface. Liquid helium at these temperatures, He II, can be regarded as an intimate mixture of two interpenetrating but extremely dissimilar fluids: a normal fluid component which behaves much like any other liquid and which carries all the thermal energy of the helium and a superfluid component which carries no thermal energy, has zero viscosity and is thus responsible for many of the more bizarre properties of the liquid. When heat enters the liquid, a counterflow of the two components occurs, with superfluid approaching the heated metal, being converted into normal fluid and then flowing away again. The authors tentatively conclude that the observed anomalous behaviour arises from the onset of turbulence in the normal fluid component within the very thin layer of helium at the surface of the metal, but further work will be necessary before this interpretation can be confirmed.

The authors have taken considerable pains to try and ensure that they have not been observing a mere artefact arising from their measuring equipment or experimental techniques. If the phenomena which they report are genuine, however, any theory of Kapitza resistance under these conditions will need to take them properly into account, so it seems highly desirable that the experiment be repeated in another laboratory as soon as possible.

Protein folding made simple

from Barry Robson

IT is hardly surprising that nobody has yet predicted how a given protein molecule folds up, considering that there are very much simpler molecules whose conformations defy theoretical analysis. Theoreticians with insatiable appetites for protein molecules, however, can restore at least a modicum of common sense by first examining protein systems in which prediction of the folding process is probably a simpler task.

Ptitsyn and Rashin (*Dokl. Acad. Nauk SSSR*, **213**, 473; 1974 and *Biophys. Chem.*, in the press) have made the first attempt to predict the folding and final overall conformation of a globular protein from its amino acid sequence and known secondary (locally organised) structure. The relatively simple protein system is in this case the myoglobin molecule which along with its haemoglobin relatives, is exceptional in being composed of α helix and very little else. Ptitsyn and Rashin justify starting with the known helical regions in terms of the popular model in which such regions are among the first features to appear during the folding up of the polypeptide chain, a model which is consistent with experimental evidence (Jardetzky *et al.*, *Cold Spring Harb. Symp. quant. Biol.*, **36**, 257; 1971; Robson and Pain, *Proc. Jerusalem Symp. quant. Chem. Biochem.*, **5**, 279; 1973; Sachs *et al.*, *Proc. natn. Acad. Sci. U.S.A.*, **69**, 3790; 1972). Furthermore, recent publications confirm that α-helical regions in proteins can be predicted with reasonable accuracy (see, for example, Chou and Fasman, *Biochemistry*, **13**, 222; 1974).

The method of Ptitsyn and Rashin is to try and predict the folding pathway and resulting most stable configuration of stacked α helices on the basis of hydrophobic interactions between the helices. They find that the most stable configuration "coincides in a rough resolution" with the native conformation. It is surprising, however, that they obtain even such an approximate structure, and it is necessary to ask whether such an agreement could be fortuitous. Helices were treated simply as cylinders with a radius of 5 Å, and dispersion, electrostatic and hydrogen bonding forces between helices are neglected except to the extent that they are included in the parameters of the hydrophobic interactions. Furthermore, a possible contribution of the helix backbone to the hydrophobic interactions was not investigated. Finally, the study was apparently carried out manually and because of the still very large number of possible configurations it would be difficult to exclude an accidental subjective element from entering such calculations where the answer is known in advance.

It is therefore possible that in retrospect the simplifications of Ptitsyn and Rashin will be seen to be too simple, and their work is likely to be best remembered for the more critical reassessments of the problem which it will undoubtedly stimulate. Nevertheless, the concept of interactions between secondary structure features such as α helices leading to the formation of single compact globules is a potent one and extends well beyond the simple case of myoglobin. The recent work of Rossman and Liljas (*J. molec. Biol.*, **85**, 177; 1974) confirms and quantifies the idea that sections of the backbone of more complicated proteins are bunched up locally to form subglobules within the overall globular structure of the molecules, so dividing many protein molecules into two or more distinct lobes. Within such subglobules, interactions between α-helical regions and other secondary structure features are probably very important.

As the first protein to have its conformation determined by X-ray crystallography, myoglobin once surprised biochemists with its unexpected complexity and the lack of any obvious relation between amino acid sequence and conformation. Now the pendulum is beginning to swing from a state of general pessimism to a state of optimism which is probably not unjustifiable.

All excited in Lisbon

from a Correspondent

THE opulent ambience of the Calouste Gulbenkian Foundation Centre in Lisbon on April 18–24 was the choice for an international conference on excited states of biological molecules under the sponsorship of the European Physical Society and European Photochemical Association, with J. B. Birks (University of Manchester) as papers secretary and editor.

As both Sir George Porter (Royal Institution, London) and G. Eisinger (Bell Laboratories, New Jersey) noted in their lectures, 1974 is about 25 years since the seminal Faraday Society Discussion of 1950, when M. Kasha discussed the phophorescence of organic molecules in terms of the Jablonski diagram and singlet–triplet conversion, and about 50 years since Perrin postulated singlet–singlet energy transfer to explain the depolarisation of fluorescence. Excited states in biological molecules were last discussed at an international meeting at Arden House, New York, in October 1969 (see *Nature*, **226**, 113–118; 1970). In the light of that report, the programme of this year's meeting had inevitably a slight sense of *déja vu*, as the main themes have not changed greatly in 5 years.

Porter reviewed the methods avail-

able for the direct observation of excited states, with particular reference to nanosecond and picosecond laser flash photolysis. He emphasised the importance of substituent effects on the reactivity of radical species formed from excited-state ketones, and the biological roles of plastoquinone and ubiquinone, which are the subject of current work in his laboratory.

C. Hélène (Centre National de la Reserche Scientifique, Orléans) gave a lucid review of excited state interactions and energy transfer processes in oligopeptide–nucleotide complexes. He described energy transfer between stacked nucleotides and aromatic amino acid chromophores in frozen aggregates at both singlet and triplet levels. It is necessary to intercalate the bound aromatic residue between the bases of single-stranded nucleic acid for quenching of fluorescence. The ability of small peptides containing an aromatic residue to bind to a small, single-stranded region of DNA containing, for example, a thymidine dimer, followed by photosensitised splitting of the dimer by energy transfer from the excited aromatic residue, provides an elegant example of a specific photoprocess in a model protein-DNA complex.

In a lecture entitled "What We have learnt about Proteins from a Study of their Excited States", G. Weber (University of Illinois) cited the demonstration of processes in the nanosecond or shorter time range, such as fast degradation of excess vibrational energy of the excited state, energy transfer between aromatic chromophores, solvent relaxation effects, molecular or segmental relaxation times and the correlation between free residue rotation and protein unfolding. He considered that with the advent of time-resolved spectroscopy on a nanosecond time scale, future work would be largely concerned with the dynamics of excited state processes. The use of differential phase fluorimetry to study solvent relaxation was described, and also the use of dissolved oxygen (under high pressure in a special cell) as an uncharged fluorescence-quenching agent. From comparisons between plots of fractional fluorescence and fractional lifetimes it is possible to determine if the quenching is homogeneously dynamic, or static and involving complexes. Of the proteins examined, some show deviations from pure dynamic quenching.

The lecture by H. T. Witt (Max-Volmer Institute, Berlin) was an impressive example of the value of a conceptual model in planning definitive experiments in such a complex field as photosynthesis. Witt demonstrated how the specific structural arrangements of the functional membrane (thylakoid) of the photosynthetic system mediates extraordinary reaction patterns not seen *in vitro*. He presented evidence in suport of the following sequence of primary acts of energy conservation and utilisation: (1) the channelling of light absorbed by bulk pigment (carotenoids and chlorophylls) by singlet–singlet transfer to photoactive chlorophyll, with a triplet–triplet transfer path from chlorophyll back to carotene to protect the former from irreversible photo-oxidation at high light intensity; (2) a specific arrangement in which always two photoactive chlorophylls are coupled in series in the membrane and are able to pump electrons from H_2O to $NADP^+$ to form NADPH; (3) the creation of a charge across the membrane; (4) the discharge of the membrane potential by H^+ fluxes through specifically organised channels (ATPase) coupled with the generation of ATP from ADP+P. It is the NADPH and ATP formed in the system which carry out the reduction of CO_2 into sugar and "everything else". The membrane potential is sufficiently high to give rise to a Stark shift in the absorption spectra of adjacent chromophores, and the shift can be regarded as a "molecular voltmeter". Some ingenious experiments to demonstrate this engaging concept were described. It seems that at least four key features of Witt's model of vectorially directed processes in the photosynthetic membrane have been confirmed experimentally.

Eisinger described a more critical approach to the interpretation of singlet energy transfer by the Förster mechanism. Since the transfer efficiency between two luminophoric groups on a macromolecule depends not only on the distance (R) between them, but also on the relative orientation of their transition dipoles, the value used for the orientation factor (κ^2) is crucial for the calculation of R. The widely-used value of 2/3 can be derived for the dynamic random averaging case, which, however, is unlikely to be relevant to real macromolecule situations. Between the extremes of fixed relative orientation, κ^2 varies from zero to 4. Eisinger and Dale have calculated contour maps showing the variation of κ^2 as the transition dipoles are given orientational freedom within cones of specified half-angles for a variety of donor-acceptor group geometries. Their analysis shows it is fallacious to assume that in practice κ^2 values near the extreme values are unlikely. They estimate the extent of orientational freedom from the limiting emission anisotropies of the separate luminophores (from time-dependent polarised emission data), and hence get reasonable upper and lower bounds for κ^2. Since information on the relative orientation of the donor-acceptor pair can be obtained from the depolarisation of transferred energy, a realistic estimate of κ^2 is possible. This procedure was used to obtain an R value for energy transfer from the fluorescent Y-base of the anticodon loop of a t-RNA to a bound dye at the remote end of the macromolecule.

S. A. Latt (Harvard Medical School) used fluorescent probes to study chromosome structure. The fluorescence of bound quinacrin is quenched by guanine–cytosine base pairs of the DNA, so that the fluorescence reveals regions with high adenine–thymine content. Furthermore, the base analogue 5-bromodeoxyuridine biosynthetically incorporated into DNA quenches the fluorescence of the dye Hoechst 33258, and can therefore be used to study the time course of DNA replication in chromosomes, and also some aspects of chromosome structure and stability.

L. G. Christophorou (Oak Ridge National Laboratory and University of Tennessee) described how threshold electron excitation spectroscopy, based on the resonant interaction of slow electrons with vapours, can be used to detect optically-forbidden transitions in aromatic compounds, including triplet states and transient negative ions. The stabilities of the double negative ion resonant states can be simply correlated with established substitution parameters of the benzene ring.

In an interesting application of luminescence spectroscopy, J. W. Longworth (Oak Ridge National Laboratory) reported fluorescence and phosphorescence data for more than 50 Bence-Jones proteins — 'light chain' dimers of γ-immunoglobulins which are secreted as individual variants in myeloma. The light chain is believed to fold in a homologous conformation, the immunoglobulin fold, and comprises two domains of approximately equal size, the variable N-terminal domain, and the C-terminal domain which is constant in all light chains of a given type. The observed diversity of fluorescence, with respect to amplitude, spectral distribution and lifetime, can be ascribed to perturbation of a single tryptophan residue in the variable domain. The phosphorescence spectra are equally diverse, often showing two decay components. Bence-Jones proteins therefore provide an excellent opportunity for studying the effects of limited variations in residue composition on the luminescence properties of a specific protein structure. There is some evidence that interaction between tryptophan and a contiguous disulphide bond is responsible for the short-lived phosphorescence, and some other contributors also considered the possible role of such an interaction in protein luminescence spectroscopy.

I. Tatischeff (Institut du Radium-

Laboratoire Curie, Paris) reported variations of the fluorescence quantum yield of the three aromatic amino acids with excitation wavelength. For all three, the yields, based on both quinine sulphate and sodium salicylate as wavelength-independent quantum counters, were constant in the longwave absorption bands, then fell abruptly to lower constant values in the shortwave absorption bands. The discussion provoked by her findings was about equally divided between explaining it away as due to experimental artefacts or inadequacy of the quantum yield standards, and in accepting them as correct and proposing possible explanations.

From the rather small number of communications concerned with small peptides and polypeptides, that by Ph. Wahl (Centre de Biophysique Moléculaire, Orléans) on the pulse fluorometry of tryptophyldiketopiperazine may be noted. He concluded that quenching of tryptophan fluorescence by the peptide bond only occurs in a folded conformer. The equilibrium constant relating the folded and unfolded conformations seems to be different in the excited and ground states; the ground state value is available from nuclear magnetic resonance studies.

An indication of new spectroscopic techniques was the inclusion of contributions on magnetic circular fluorescence and fluorescence polarisation and on magnetic circular dichroism in the near infrared. The shorter papers on visual pigments were concerned with problems of singlet-triplet intersystem transfer and *cis–trans* isomerisation of polyenes, and in the large number of communications on photochemical reactors, the roles of singlet and triplet oxygen were frequently discussed.

Management of aquatic weeds

from Peter D. Moore
Plant Ecology Correspondent

AT the close of the International Hydrological Decade it is only natural that the world of waterweeds and the problems associated with their control should be receiving some attention in the scientific literature. It is natural too that the problems of the developing countries should receive greatest prominence, for here many essential programmes of irrigation are being set back by the luxuriant and rapid growth of aquatic vegetation in tropical climates. India, most especially, has been at the fore in a series of recent publications on this subject.

Gupta has summarised many of the Indian problems and some of their solutions in his booklet *Aquatic Weed Control* (Rajasthan College of Agriculture, Udaipur, 1973). In Rajasthan the development of a canal system is relieving a serious problem of water distribution; many women were forced to walk several kilometres to fetch pitchers of water from surface ponds. The canal projects, however, have suffered severely because of the growth of aquatic weeds, particularly water hyacinth, *Eichornia*, and the water ferns *Azola*, *Wolfia* and *Salvinia*. From April to June the canals are closed so that clearance by hand can take place, but this control method is ineffective in the long term. Only one mechanical weed cutter operates in Rajasthan but biological control using Chinese carp is being attempted; the use of chemical herbicides is prohibitively expensive. The same sad picture of India's plight emerges from the recent UNESCO symposium held in New Delhi and reported by Tinker (*New Scientist*, **61**, 747; 1974).

Weed Research Organisation

Water channel in India infested with the water hyacinth *Eichornia*.

A very full review of the entire problem has now been published by UNESCO (*Aquatic Vegetation and its Use and Control*, edit. by D. S. Mitchell, Paris, 1974). Although the theoretical consideration of the mathematics of waterweed population growth and the technique of mechanical, chemical and biological control of waterweeds are undoubtedly important as short term approaches to the aquatic vegetation problem, data presented by Boyd (University of Auburn, Alabama) in this collection of papers provide hope for a more permanent solution. The explosive growth of aquatics is itself an indication of eutrophication and nutrient wastage which can ill be afforded, especially in countries such as India. Boyd considers ways in which waterweeds could assist in the retrieval of these last elements.

Many waterweeds provide a better feed for livestock than dried alfalfa hay. Generally they contain rather less crude protein and fibre, but more ash and fat than this commodity. Inorganic ion concentration in aquatics falls within the range generally accepted for crop plants; ash values of more than 25% of the dry weight are recorded, the noxious weed of many Indian waterways, *Hydrilla verticillata*, being responsible for some of the higher figures.

Before these nutrients can be re-used by crops they must be released from the organic tissues of the water plants, and decomposition is not always rapid. *Eichornia* compost takes about 3 months of fermentation before it is suitable for use as a fertiliser. Nevertheless, when it is considered that eutrophicated waters can support a standing crop of 29 t ha^{-1} (dry weight) of *Eichornia* containing 157 kg ha^{-1} of phosphorous and 693 kg ha^{-1} of nitrogen, this process must be considered an important means of cutting nutrient losses.

In the developed countries the cost of retrieving lost nutrients from solution usually exceeds the cost of supplying new ones. In countries such as India, where manual harvesting is cheap and where the foreign exchange needed for chemical fertilisers is in short supply, the use of aquatic vegetation for nutrient recovery may prove to be economically feasible.

Pistia stratiotes.

What is the nuclear optical potential?

from Peter E. Hodgson, Nuclear Physics Laboratory, Oxford

THE interaction of a nucleon of moderate energy with a nucleus is an exceedingly complicated process. Very many reactions can occur and they depend on the energy levels of the compound and residual nuclei. The conservation of particle flux links all the reaction channels together, so that any abnormal behaviour in one channel, a resonance or threshold for example, produces corresponding changes in all the others. It might well be thought that each interaction would have to be treated as a special case and that the detailed structure of each nucleus would have to be taken into account before the cross sections could be calculated.

One-body potential

In spite of this somewhat pessimistic expectation, the striking regularities in the neutron total and reaction cross sections as a function of energy and from nucleus to nucleus suggested that they could be described by a one-body potential varying smoothly with energy and nuclear size. (Feshbach, Porter and Weisskopf, *Phys. Rev.*, **96,** 448; 1954). The success of this description led to the model being extended to nucleon elastic scattering and the range of other nuclear interactions.

Subsequently it was realised that this success was partly due to the relatively poor energy resolution of the early measurements. Later improvements in experimental techniques showed that the cross sections of reactions passing through the compound nucleus do fluctuate as the incident energy varies (Von Brentano *et al.*, *Phys. Lett.*, **9,** 48; 1964) but if the energy spread of the incident beam is greater than the mean width of the fluctuations an averaged cross section is obtained that generally varies quite smoothly with energy. Detailed analysis showed that this averaged cross section is the sum of compound nucleus and direct reaction components; the former may be calculated using the theory of Hauser and Feshbach (*Phys. Rev.*, **87,** 366; 1952) and subtracted from the measured cross sections. As the energy increases the contribution of the compound nucleus processes falls rapidly and soon becomes negligible.

In precision analyses it is necessary to remove the compound nucleus contribution to the data by a preliminary Hauser–Feshbach calculation or preferably to confine the analysis to energies for which the compound nucleus contribution is negligible. For most nuclei, energies of about 15 MeV or more are adequate for this purpose. The direct cross section is then analysed by a simple optical potential.

Many such analyses were made and soon it was possible to specify potentials defined by rather few parameters that give strikingly good overall fits to a wide range of neutron and proton elastic scattering and reaction data (Perey, *Phys. Rev.*, **131,** 745; 1963; Perey and Buck, *Nucl. Phys.*, **32,** 353; 1962). One of the most successful of these potentials was obtained by Perey from an analysis of the elastic scattering of protons of 9–22 MeV by a range of medium and heavy nuclei. He used a potential of the form

$$V(r) = U_0 f(r_u,a_u) + ia_D W_D(d/dr)[f(r_D,a_D)] + (\hbar/m_\pi c)^2 U_s(1/r)(d/dr)[f(r_s,a_s)]\mathbf{L}.\sigma$$

where

$$f(r_i,a_i) = [1+\exp\{(r-r_i A^{1/3})/a_i\}]^{-1}$$

In the first analyses, the parameters of this potential were adjusted to optimise the fit to each set of data for scattering from a particular nucleus at a particular energy. The most accurate data were the differential cross sections, supplemented by less accurate polarisations and reaction cross sections.

The optimum parameters for different nuclei at different energies were found to be very similar, so the data were reanalysed fixing the form factor parameters to the values

$$r_u = 1.25;\quad r_D = 1.25;\quad r_s = 1.25$$
$$a_u = 0.65;\quad a_D = 0.47;\quad a_s = 0.65.$$

The quality of the fits was still very high, though naturally not quite as good as previously.

The depth of the real potential was found to vary systematically with energy and with the numbers of neutrons and protons in the nucleus, and the variation could be well represented by

$$U = 53.3 - 0.55E + 27\alpha + 0.4Z/A^{1/3}$$

where $\alpha = (N-Z)/A$

The optimum imaginary potential was not so well determined, but a good average value is

$$W_D = 12A^{1/3}$$

The polarisations were best fitted with

$$U_s = 7.5 \quad (E < 17);\quad U_s = 8.5 \quad (E > 17)$$

The fits obtained with this overall potential are very little worse than those obtained when several parameters were adjusted in each case.

Global potential

The striking success of these analyses led to the hope that it would be possible to find an overall or global potential for all nuclei and one has tended to forget that the individual structure of each nucleus must affect the interaction to some extent. This raises difficulties concerning the concept of the optical potential, in particular whether it should give a good overall fit to many sets of data or whether it should be adjusted to fit each set of data as accurately as possible.

Optical potentials of the first type are the same for all nuclei, with perhaps a smooth and easily parameterised dependence on the incident energy and on Z and A. To achieve this one has inevitably to make some sacrifice in the quality of the fits to the data.

Optical potentials of the second type have parameters that are unique to each nucleus at each energy, so that accuracy has been purchased at the expense of loss of generality.

Both types of potentials have their advantages and disadvantages. In some interactions there are quite substantial deviations from the behaviour given by the overall potential, whereas potentials fitted accurately to particular sets of data are sometimes recognisably non-physical. These anomalies have a physical basis, so that one might hope that detailed studies with both types of potential could teach us more about the physical process taking place.

It is important to see what can be done to eliminate the disadvantages of these potentials while preserving their good points. The first step is to identify the physical processes responsible for the deviation from 'normality' and make a physical model that allows them to be calculated explicitly. If this can be done within the framework of the optical model, then the process and its effect on the cross section can be represented by an extra term in the optical potential. In this way, for example, the polarisations of the elastically scattered nucleons were included in the model by the addition of the spin–orbit term to the potential and the dependence on the asymmetry parameter by the term proportional to $(N-Z)/A$.

Small terms

At one stage it was hoped that all new physical effects and deviations from the simpler potential could be brought within the general optical potential by the addition of a series of small terms, giving a potential expressible as a simple analytical function of A and E and capable of fitting the elastic scattering data to high accuracy.

Unfortunately in recent years several deviations from normality have been found that can be understood physically but which cannot be treated in this way. These are of two types; the first can still be treated within the optical model formalism whereas the second requires more sophisticated theoretical treatment.

An example of the first is the exceptionally low neutron reaction cross sections found for magic nuclei at low energies, especially for ^{208}Pb (Perey and Buck, 1962). These are much less than those calculated from the highly successful Perey–Buck potential and can easily be understood as a consequence of the low level density at small excitation energies of such nuclei. The effect can be treated phenomenologically by allowing the absorbing part of the optical potential to depend on the shell structure but the absorbing potential cannot conveniently be expressed as an analytical function of Z and A. This phenomenon only occurs in a limited energy region and is not of general importance.

The effects in the second category may be calculated by appropriate physical models but it is not possible to represent them by an easily-parameterised additional term in the optical potential. It is of course often possible to fit the data through the region of the anomaly with a particular optical potential, so that one can formally define the potential responsible for the effect as the difference between the general optical potential and the particular potential, but this is often highly singular and not conveniently parameterisable.

The extent to which this occurs implies a breakdown of the simple optical model, so that one is now faced with the alternatives of either using an ill-behaved effective potential in the framework of the simple optical model or of continuing to use a general optical potential in a more sophisticated formal framework. The second alternative is clearly the more desirable, even from the purely phenomenological point of view, as it often unifies a range of phenomena in a simple way, whereas the effective potentials are much more difficult to handle.

This may be illustrated by the analysis of elastic scattering from strongly deformed nuclei. These have low lying collective states that are readily excited by inelastic scattering and the cross sections are so large that the elastic scattering cross section is significantly affected.

The inelastic cross sections vary in magnitude with β, but hardly at all in shape, and the elastic cross section departs more and more from its unperturbed value as β increases. If the elastic cross section is analysed for several deformed nuclei, the parameters of the resulting potential vary from nucleus to nucleus depending on the strength of the coupling to the collective states.

In particular, the imaginary potential is found to increase with increasing deformation. A coupled-channels analysis can, however, fit the elastic cross section with the same optical potential for each nucleus provided each has its characteristic deformation parameter. This was first shown by Perey (in *Nuclear Spectroscopy with Direct Reactions* (edit. by Throw) ANL-6848, 114; 1964) in an analysis of the elastic scattering of protons of 17 MeV off some heavy spherical and deformed nuclei.

Another example is provided by the scattering of α particles of 50 MeV by the even isotopes of samarium (Glendenning, Hendrie and Jarvis, *Phys. Lett.*, **26B**, 131; 1968). The elastic scattering changes qualitatively from one isotope to the next; the diffraction oscillations become less and the envelope of the maxima steeper as the mass (and the nuclear deformation) increases. Simple optical model analyses of these data give quite different potentials, but the cross sections are all well fitted by the same optical potential when the coupling to the collective states is taken into account and each nucleus is characterised by its deformation parameter. The deviations from simple normality can thus be brought within the scope of the general optical model, although the deformation parameter cannot be expressed as an analytical function of Z and A.

Coupled-channel analyses

Further evidence for the reduction of the absorbing potential in the region of closed shells is provided by measurements of the s and p-wave strength functions. These show characteristic maxima and minima as a function of A and the overall behaviour is quite well given by the optical model with standard potentials. Closer examination shows that although the maxima are quite accurately fitted, the experimental values are much less than the calculated ones in the regions of the minima. A coupled-channels analysis by Newstead (in *European Conference on Intermediate Reactions*, Plitvice; 1972) found that this behaviour can be obtained by reducing the imaginary potential in a way that varies from nucleus to nucleus. Since the imaginary potential corresponds to absorption it might be expected to be correlated with the number of three-quasiparticle states that can be formed in the initial stages of the nuclear excitation. Newstead estimated the numbers of such states in various nuclei and found that they correlate very well with the imaginary potentials W obtained by requiring a fit to the s-wave strength function data. Thus once again the deviations from normality can be explained by a physical model but not in a way that can easily be parameterised in terms of A and Z.

Another effect that can easily be treated by the coupled-channels formalism is the marked resonances that occur when low energy nucleons are scattered by some light nuclei (Mikoshiba, Terasawa and Tanifugi, *Nucl. Phys.*, **A168**, 417; 1971). Some of these are single-particle resonances in the optical potential; others can be understood as core-excitation resonances. The coupled-channels formalism with a simple model of the nuclear excitation gives a good overall account of these resonances. The data also show higher order resonances that could presumably be treated by including the coupling to more complicated configurations.

The scattering from light nuclei at higher energies frequently shows deviations from normality and in some cases this is due to higher order processes. In the case of medium-energy proton scattering by ^{12}C and ^{16}O the core-polarisation exchange mechanism with intermediate excitation of a giant resonance is responsible for the marked peaks in the backward cross section for inelastic scattering to non-normal parity states that cannot be accounted for by the simple optical model (Von Geramb, *Nucl. Phys.*, **A199**, 545; 1973; *Nuovo Cim. Lett.*, **5**, 333, 1972). This effect reflects back on the elastic channel and so should be taken into account explicitly at those energies where giant resonances are important.

As a final example, the (p, n) quasi-elastic reaction to the isobaric analogue state has significant contributions from the two-step (p, d, n) intermediate particle transfer process (Rickertsen and Kunz, *Phys. Lett.*, **47B**, 11; 1973). If it is analysed with a simple optical potential the fits are not strikingly good and the parameters of the isospin term which is responsible for the transition vary erratically from nucleus to nucleus. If the two-step process is included explicitly, making use of the properties of the known intermediate states, then the fits are significantly improved and the isospin potential is essentially the same for all nuclei. Thus once again by treating explicitly the process responsible for the deviations it is possible to recover a general optical potential.

Polarisations

The polarisations of the elastically scattered particles are much more sensitive to the interaction potentials than are the differential cross sections, as they depend on the differences of scattering amplitudes. This sensitivity

is to a large extent offset by the lower accuracy of the polarisation data, but nevertheless careful analyses of polarisations have shown anomalies that are not yet understood.

An example of this is provided by the work of Boschitz (*Phys. Rev. Lett.*, **17**, 97; 1966), who analysed a series of differential cross sections and polarisations. He was able to obtain good overall fits to the polarisation data but the optimum values of the parameters of the spin–orbit term in the optical potential showed marked variations from one nucleus to another and as a function of proton energy. So far there is no convincing explanation of this behaviour.

From these examples it will be seen that the processes that must be considered explicitly are of several types. The polarisation and the dependence on the nuclear asymmetry can easily be incorporated in the optical model. The others require quite sophisticated calculations before the effects due to the general optical potential and the special process can be disentangled. The calculations with both processes included give directly the elastic cross section and there is no effective optical model potential as an intermediate stage. It is thus not possible to think of a general optical potential in which the effects of coupling to excited states, two-step reactions, core-polarisation exchange processes and so on are included by appropriate analytical terms in a general expression of the optical potential. In this sense the optical potential ceases to be a concept able to give a detailed physical account of all the data; it has been superseded in some regions by more sophisticated calculations that give an accurate account of the data that cannot be obtained in any other way.

One has thus arrived at a third concept of the optical potential as one that includes as many effects as possible in the parameterisation of its parameters as functions of Z and A but which has to be used in a more sophisticated formalism if certain other effects are to be treated adequately. Thus some of the simplicity of the model has been lost, but further insight into more complicated phenomena has been attained.

I thank Dr R. S. Mackintosh for discussions and suggestions.

Correction

In the News and Views article "Vegetational change in an aboriginal environment" (*Nature*, **249**, 11; 1974), the date in line 7 of the first paragraph should be 5,500 radiocarbon years.

Biogenesis of surface membranes

from R. Colin Hughes

ACCORDING to the membrane flow theory, membrane biogenesis involves the physical transfer of membranes from one subcellular compartment to another. The endoplasmic reticulum is the precursor of Golgi membrane which is in turn processed into plasma membrane. Surface membrane proteins and glycoproteins, therefore, are considered as a special class of secreted substances.

The basic assumption of the theory, that membrane proteins are synthesised on the rough endoplasmic reticulum, must obviously be re-interpreted, however, since Lodish (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 1526–1530; 1973) and Lowe and Hallinan (*Biochem. J.*, **136**, 825–828; 1973) have described synthesis of some membrane proteins on free polysomes. The converse proposal that soluble cytoplasmic proteins are made only on free polysomes is similarly an oversimplification. At least one soluble enzyme, serine dehydrase, is synthesised on membrane-bound ribosomes and a similar role seems likely in non-secretory tissues such as brain or muscle. So far as membrane proteins are concerned, it is possible that integral membrane components are made in a way different to extrinsically bound proteins. Synthesis of glyceraldehyde-3-phosphate dehydrogenase on cytoplasmic polysomes is expected, for example, yet this protein forms stable interactions with high affinity for a limited number of sites on the cytoplasmic face of the erythrocyte membrane (Kant and Steck, *J. biol. Chem.*, **248**, 8457–8464; 1973). The enzyme seems therefore to be a specific membrane component, made on free polysomes.

An indication that integral proteins, by contrast, may follow an intracellular route analogous to the secretory process comes from an extensive radioautographic study by Leblond and his colleagues (*J. Cell Biol.*, **60**, 258–284; 1974). This suggests a final step in surface membrane biogenesis in which fusion takes place between the cell surface membrane and Golgi vesicles, the membranes of which carry proteins and glycoproteins destined ultimately for the surface membrane. The chief difficulty in accepting completely this proposal, is that the membrane composition of highly purified rat liver Golgi membranes, as described recently by Palade *et al.* (*J. Cell Biol.*, **59**, 45–72; 73–88; 1973) is clearly different to the homologous plasma membrane. The role of the Golgi vesicles therefore, may be to ferry a few proteins from intracellular smooth membranes to the cell surface as follows: fusion of the vesicles with the cell surface membrane, lateral diffusion of selected proteins into the area of plasma membrane surrounding the fusion site and finally re-entry of the Golgi vesicular membrane into the cell by endocytosis. In this case, the membranes of Golgi vesicles before fusion would contain a relatively small proportion of plasma membrane components superimposed on a background of purely Golgi membrane proteins and after fusion only Golgi specific proteins.

The membrane flow theory also predicts that at earlier stages of membrane biogenesis, the proteins and glycoproteins are restricted to membrane-bounded intracellular vesicles. Presumably, the membrane precursors made on membrane-bound ribosomes are either discharged into the lumen of the endoplasmic reticulum to be inserted into smooth membranes elsewhere or remain inserted directly into membranes at their sites of biosynthesis. Hirano *et al.* (*Proc. natn. Acad. Sci. U.S.A.*, **69**, 2945–2949; 1973 found earlier that the membranes of rough microsomal vesicles are assymetrically substituted with carbohydrate groups, capable of reacting with certain lectins coupled with ferritin. The membrane facing inwards carried carbohydrate whereas the cytoplasmic face did not. Since the intralumenal face of the endoplasmic reticulum is equivalent to the external face of the plasma membrane, at which carbohydrates are also localised, this finding is interpreted as a flow of membrane with retention of configuration from intracellular biosynthetic sites to the cell surface. It does not, of course, prove that this is the case. Kreibach *et al.* (*Fed. Proc.*, **32**, 2133-2138; 1973; *J. Cell Biol.*, **60**, 616–627; 1974) now confirm these observations by testing the accessibility of rat liver microsomal proteins to lactoperoxidase labelling. The glycoproteins are labelled only when the closed microsomal vesicles are made permeable by treatment with low concentrations of detergents. Two classes of glycoproteins are labelled; one class is released by mild detergent treatment whereas the other requires higher detergent concentrations and disassembly of the microsomal membranes. It is not clear, however, whether these last components are stable membrane constituents or precursors of glycoproteins.

The glycoproteins detected by Hirano *et al.* and Kreibach *et al.* are not known to be precursors of surface membrane glycoproteins and could equally well be glycoproteins destined for secretion. The next step is application of the techniques for the selective solubilisation of microsomal glycoprotein precursors to defining the kinetics of flow of these substances.

Gangliosides as membrane receptors for tetanus toxin, cholera toxin and serotonin

W. E. van Heyningen

Sir William Dunn School of Pathology, University of Oxford, UK

Tetanus toxin is bound by a sialidase-labile disialosyl ganglioside, serotonin by another, and cholera toxin by a sialidase-stable monosialosyl ganglioside. There is good evidence that the monosialosyl ganglioside may be the receptor for cholera toxin in cell membranes; what of the disialosyl ganglioside and tetanus toxin?

THERE has been a sharp rise in interest in the possible biological roles of the gangliosides, discovered by Klenk in 1935–42[1,2]. These versatile substances have been virtually ignored in recent authoritative reviews on the structure of cell membranes[3,4], in spite of a number of characteristics which indicate that they might be considered as possible functional components of cell membranes. First, they have an amphiphilic nature, as they are composed of lipophilic ceramide moieties and hydrophilic oligosaccharide moieties; second, in nervous tissue, which is the richest source of gangliosides, they have found to be concentrated in fractions containing synaptic membranes[5,6]; third, they are being found in an increasing number of biological preparations[7]; fourth, although they are water soluble they are almost invariably not extractable with water from biological material, which indicates that they are bound to hydrophobic components[8,9].

(Bretscher[4] proposes that the outer layer of the membrane lipid bilayer is largely composed of ceramidyl phospholipids, and that the glycolipids are located solely in this layer. In such a scheme it would be reasonable to speculate that the ceramidyl moieties of the gangliosides may be buried, leaving the hydrophilic oligosaccharide moieties exposed on the outsides of the membranes.)

No particular function for the gangliosides has, up to now, been clearly demonstrated, but recently there has been an accumulation of evidence that cholera toxin may recognise a particular ganglioside on the surfaces of cell membranes. These observations revive interest in earlier observations of a specific interaction between tetanus toxin and two other gangliosides, and between serotonin and another ganglioside.

Tetanus toxin

Tetanus toxin is a neurotoxin, thought at first to act only on the central nervous system (CNS), producing spastic paralysis by blocking synaptic inhibition in the spinal cord, but now known to act peripherally as well, producing flaccid paralysis by blocking neuromuscular transmission[10,11]. In its action on nervous tissue, it produces no morphologically distinguishable changes in the tissue, yet it binds with the tissue. This was first shown in 1898 by Wassermann and Takaki who found that when a homogenate of nervous tissue was mixed with a solution of tetanus toxin and the suspension filtered, the concentration of toxin in the filtrate was diminished[12]. This phenomenon was investigated by many workers, including Landsteiner, who believed that the substance in nervous tissue responsible for the binding was a cerebroside, but was puzzled by the fact that grey matter had a greater capacity to bind the toxin than white matter, but had a lower cerebroside content[13]. I reinvestigated the Wassermann-Takaki phenomenon and showed that it was apparently tissue specific and toxin specific (that is, of all the tissues tested only nervous tissue bound the toxin, and of all the known bacterial toxins tested only tetanus toxin was bound[14]). When these tests were reported in 1959 cholera toxin was not yet known, its existence being reported by De in the same year[15].

It was then shown that the binding of tetanus toxin was due to the then comparatively unknown substance, ganglioside. It was also shown that there were at least three gangliosides in nervous tissue, differing in their sialic acid contents and their

tetanus toxin-binding capacities, which increased with increasing sialic acid content[16]. Later, when the multiplicity and nature of gangliosides was better understood, it was shown that tetanus toxin had an affinity for two particular gangliosides containing two sialic acid residues attached to the lactose component[17] (Table 1).

Tetanus toxin does not seem to lose its toxicity as a result of being bound by ganglioside; nor does the ganglioside seem to be altered. If tetanus toxin (50 ng ml^{-1}) is incubated in the presence of gelatin for 1 h at 37° C with the gangliosides GGnSSLC and SGGnSSLC (300 μg ml^{-1}, molar ratio of ganglioside to toxin of 4×10^6:1) there is no reduction in toxicity[18]. If 5 mg of mixed gangliosides (containing about 1 mg of GGnSSLC+SGGnSSLC) are injected intramuscularly into mice, however, followed 5 h later by an injection of 0.5 LD_{50} of toxin in the same site, the mice are protected against the more severe degrees of tetanus, but in this case the molar ratio of ganglioside to toxin is much greater (3×10^9:1) (ref. 19).

The interaction between tetanus toxin and ganglioside can be observed in two ways. First, a solution of tetanus toxin (5mg ml^{-1}) and ganglioside (0.1 to 0.5 mg ml^{-1}) is centrifuged in an analytical ultracentrifuge. The complex of ganglioside and toxin will move rapidly down the centrifugal field, leaving some unbound toxin, the amount of which by difference from the original gives the amount bound[16] (Table 1). Second, ganglioside is rendered insoluble by complexing it (as a mixed micelle?) with insoluble (and unreactive) cerebroside, and varying amounts of the complex are suspended in equal volumes of a solution containing about 1.5 ng toxin ml^{-1} (about 45 LD_{50} ml^{-1}). The insoluble ganglioside–cerebroside–toxin complex is spun down and the supernatant tested for toxicity in mice. In this way the least amount of ganglioside that will bind (say) 10 LD_{50} of toxin can be determined. Not surprisingly, at these low concentrations of toxin far less toxin is bound per unit weight ganglioside than at concentrations 3 million times greater, but the differences between the toxin-binding capacities of different gangliosides are still evident (Table 1). The proportion of ganglioside in the insoluble complex is critical—thus complexes containing 25% ganglioside have a much greater capacity to bind tetanus toxin (and to protect mice against the toxin) than have complexes containing either 5 or 50% ganglioside[9].

If relatively high concentrations of almost any ganglioside in solution are incubated for long periods with almost any toxin in the absence of a protective protein such as gelatin, the toxin will be inactivated. This nonspecific effect is of little interest, but has led to some confusion[18].

So far, the specific interaction between tetanus toxin and the sialidase-labile gangliosides GGnSSLC and SGGnSSLC has not thrown any light on the mode of action of the toxin at the molecular level.

Serotonin

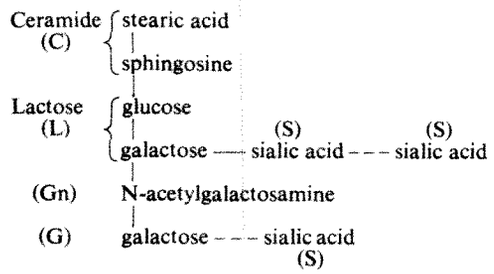
I have shown that mixed gangliosides in solution bound serotonin (5-hydroxytryptamine), tryptamine, lysergic acid diethyl amide, and ergometrine, but not adrenaline, noradrenaline, dopamine, histamine, or γ-aminobutyric acid; they also bound the convulsant drug strychnine and the related drugs brucine and thebaine[17]. I later found, however, that serotonin and strychnine were not bound by the ganglioside–cerebroside complexes that have such a great affinity for tetanus toxin[9]. The effect of ganglioside on serotonin has since been shown in other ways. Strips from rat stomach respond to serotonin, and Woolley showed that this response was diminished if the stomach strips were treated with sialidase, and restored if ganglioside was added to the enzyme-treated strips. Similar results were obtained with strips from ganglioside-deficient stomachs from rats reared on a galactose-rich diet[20]. Gielen identified the serotonin-reactive ganglioside as the sialidase-labile SSLC (which, lacking the terminal galactose and the N-acetylgalactosamine residues, is unlikely to interact with tetanus toxin)[21]. But the intact cat erythrocyte contains SSLC, yet is incapable of binding serotonin. This is reminiscent of the observation mentioned above that mixed gangliosides in free solution bound serotonin, but not when complexed with cerebroside.

Cholera toxin

The actions of cholera and tetanus toxins could be considered similar in the sense that they both affect the passage of substances across cell membranes (those of intestinal epithelial cells and nerve cells respectively) without producing any morphological changes in their susceptible tissues. Cholera toxin has been isolated by Finkelstein as a protein with a molecular weight of 84,000 (ref. 22). In the final stages of purification of the toxin, it is possible to isolate an inert protein, choleragenoid (molecular weight 58,000), that is nearly, but not quite, immunologically identical with the toxin, and possibly derived from it[22]. When cholera toxin is introduced into the lumen of the small intestine, it causes an accumulation of fluid, leading to diarrhoea[15,22]. When introduced intracutaneously it causes a local increase in capillary permeability[23]. Indeed, the toxin acts on a wide variety of tissues and cells[22], in which the effect usually appears to be mediated through the activation of adenylate cyclase. The subsequent increased levels of cyclic AMP in turn promote a wide variety of actions, including in the case of the intestinal epithelium, the secretion of chloride ions[22,24].

My collaborators and I have shown that homogenates of intestinal epithelium have a marked capacity to bind cholera toxin, whereas homogenates of liver, kidney, lung and heart seem to have no such capacity. Brain homogenate, however, proved even more effective than intestinal cells and it was then a simple step to show that mixed gangliosides were capable of binding the toxin, and were likely to account for the ability of these tissues to do so (brain contains about ten times as much ganglioside as intestinal cells)[25]. Ganglioside not only binds cholera toxin, but, unlike the case with tetanus toxin, it also blocks its action in the small intestine, in the skin, and elsewhere. I then showed that of all the brain gangliosides, only the sialidase-stable monosialosyl ganglioside, GGnSLC (G_{M1}) had this effect[26,27] (Table 1). The presence of a single sialic acid residue attached by a sialidase-labile bond, even to the terminal galactose residue, completely abolishes the capacity of the ganglioside to interact with cholera toxin. Also, treatment of intestinal epithelial cells with sialidase, an enzyme itself produced by the cholera bacillus, greatly increases their capacity to bind cholera toxin[26].

The blocking of the action of cholera toxin by added ganglioside indicates that when the toxin is bound to the extraneous ganglioside it is unable to attach itself to the receptor on the cell membrane, and therefore that the ganglioside GGnSLC may be very similar to, and even identical with, the membrane receptor of the toxin. GGnSLC also binds the biologically inert choleragenoid, and Pierce has shown that choleragenoid will block the action of cholera toxin in the small intestine, if placed in the intestine in advance of the toxin, one molecule of choleragenoid blocking one molecule of cholera toxin[28]. King and I (unpublished data) have shown that one molecule of choleragenoid will block the capacity of ganglioside (in the form of a ganglioside–cerebroside complex) to block the activity of nearly one molecule of cholera toxin. These data suggest the possibility that choleragenoid may be the part of the cholera toxin molecule that is responsible for the binding of the toxin to the receptor on the cell membrane. This has been supported and amplified by Simon van Heyningen[29] who has shown that when cholera toxin is bound to an insoluble GGnSLC–cerebroside complex, a component, A (molecular weight about 22,000), may be eluted with neutral 8 M urea. In spite of



treatment with 8 M urea, this component has about 1% of the activity of the original toxin as tested in the rabbit skin. This activity is distinguished from that of the whole toxin by being unaffected by GGnSLC. The remaining portion of the toxin, in subunits B (molecular weight about 15,000), may be eluted from the ganglioside–cerebroside complex with neutral 6 M guanidine hydrochloride. Subunits B migrated with the same rate as subunits of choleragenoid on electrophoresis in polyacrylamide gel containing 6.25 M acid urea; after removal of the guanidine hydrochloride they were bound again by

Table 1 Interactions of the best-known gangliosides with tetanus and cholera toxins

Toxin	Molecules toxin bound per molecule ganglioside: Tetanus		Cholera
Test	Ultracentrifuge	Toxicity	Toxicity
Toxin concentration	5 mg ml^{-1}	1.5 ng ml^{-1}	10 ng ml^{-1}
Ganglioside*			
GnSLC (G_{M2})	< 0.005		< 0.000,5
GGnSLC (G_{M1})	0.04	0.000,05	0.35
SGGnSLC (G_{D1A})	0.04		< 0.000,5
GGnSSLC (G_{D1B})	0.28	0.000,6	< 0.000,5
SGGnSSLC (G_{T1})	0.28		< 0.000,5

The two sialic acid residues attached to the lactose component are necessary for optimal interaction with tetanus toxin, as is the terminal galactose residue; but the sialic acid residue attached to it seems to play no part. Only one ganglioside, which is sialidase-stable, interacts with cholera toxin, and the terminal galactose residue is again necessary for the interaction.

* It is convenient to use McCluer's abbreviated nomenclature for gangliosides[37] as it is self explanatory, and no less scientific than the widely used nomenclature of Svennerholm given in the brackets[38]; thus, the trisialosyl ganglioside, sialosylgalactosyl-N-acetylgalactosaminylsialosylsialosyllactosylceramide (G_{T1}), becomes SGGnSSLC:

(Broken lines signify sialidase-labile bonds)

GGnSLC, and showed immunological identity with choleragenoid. These data indicate that cholera toxin consists of two parts: a larger portion corresponding to choleragenoid (composed of subunits B) which combines with the GGnSLC receptor on the cell membrane, and thus facilitates the entry of the toxin into the cell; and a smaller portion, component A, which does not combine with GGnSLC and is, somehow or another, responsible for the activity of the toxin within the cell. This is reminiscent of aspects of the composition and activity of diphtheria toxin[30,31], and of the toxic plant proteins, abrin[32] and ricin[33].

The specific blocking action of cholera toxin by the ganglioside GGnSLC (G_{M1}) has subsequently been confirmed by Holmgren[34,35] and by Cuatrecasas[36]. Cuatrecasas has made the interesting observation that if exogenous GGnSLC is added to cells (lipocytes), and the excess ganglioside is washed from the cells, the capacity of these cells to bind and to react to subsequently added cholera toxin is increased. This observation is reminiscent of the effect, discussed in the previous section, of added exogenous ganglioside SSLC in restoring the reactivity to serotonin of ganglioside-deficient stomach strips. Cuatrecasas suggests that the added exogenous ganglioside is actually incorporated in the cell membrane, thus providing more receptor sites for the toxin. This is an interesting suggestion, but there is as yet no direct evidence of incorporation of ganglioside, only increased binding of, and reactivity to, the toxin, and there may be other explanations. For example, added ganglioside might remove some substance blocking preexisting receptor sites (Gill, private communication).

Gill and King (unpublished data) have confirmed that added exogenous GGnSLC increases the response (measured in terms of adenylate cyclase activity) of intact pigeon red blood cells to cholera toxin, provided always that the amount of ganglioside is not in excess (otherwise the toxin would be blocked). If the red cells are first lysed with a bacterial haemolysin, the resulting ghost cells are still reactive to cholera toxin, but the reactivity is not increased by the addition of ganglioside. This indicates that if the toxin can enter the cell by some other means it does not need the entry by binding to the receptor on the outer surface of the cell membrane.

The accumulated evidence that the ganglioside GGnSLC is the receptor for cholera toxin is persuasive, and rekindles interest in the specific reaction between tetanus toxin and GGnSSLC (and SGGnSSLC). Are these the receptors for tetanus toxin on the membranes of nerve cells? Or, as tetanus toxin has both a central and a peripheral action, and as botulinum toxin (which does not react specifically with ganglioside) has only a peripheral action (indistinguishable from that of tetanus toxin), is GGnSSLC responsible only for the central action of tetanus toxin?

Joint transcription of two $tRNA_1^{Tyr}$ genes from *Escherichia coli*

Alain Ghysen*

Julio E. Celis†
Medical Research Council Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

Biochemical evidence suggests that the two $tRNA_1^{Tyr}$ genes of E. coli *are transcribed together as a single precursor. A nuclease activity which cleaves incorrectly but specifically the $tRNA^{Tyr}$ precursor has been revealed.*

THE $tRNA_1^{Tyr}$ species of *Escherichia coli* is coded for by two closely linked genes[1]. In *sup*3 mutants, one of these genes has a mutation in the anticodon which allows the tRNA to read UAG[2]. *sup*3-Transducing phages have been constructed. One of them, referred to here as φ80*psup*3 (Kyoto), carries both the suppressor gene and the adjacent wild-type gene[3]. The other will be referred to as φ80*psup*3 (Cambridge), it carries only the suppressor gene as a result of an unequal recombination deleting the wild-type gene[1]. Using φ80*psup*3 (Cambridge), Altman and Smith have shown that the single $tRNA_1^{Tyr}$ gene is transcribed as a precursor containing 41 extra nucleotides at the 5′ end and a few nucleotides at the 3′ end of the mature tRNA sequence[4]. This precursor is then cleaved at the 5′ end of the tRNA sequence by a specific endonuclease, RNase P[5]. The extra 3′-end nucleotides are subsequently removed by a different enzyme. The transcription and maturation scheme is not known in the normal situation where the two genes are present.

We recently reported the characterisation of mutations affecting the *sup*3 gene carried by φ80*psup*3 (Kyoto)[6]; some of these result in greatly diminished synthesis of tRNA because of the low efficiency of correct processing of the tRNA precursor. Similar mutants in φ80*psup*3 (Cambridge) have previously been shown to reduce the yield of suppressor tRNA[7]. Two such mutants are A1 and A2. Other mutants such as U80, U81 and G82 do not appreciably alter biosynthesis of the mutant tRNA. Here we asked the question whether mutants A1 and A2 in the suppressor gene of φ80*psup*3 (Kyoto) also lower the amounts of tRNA synthesised by the neighbouring wild-type $tRNA_1^{Tyr}$ gene. If the two genes are transcribed independently as separate precursor tRNAs, mutations in the suppressor gene would not be expected to alter the synthesis of the wild-type gene.

Our results suggest that the two tRNA genes are transcribed together as a common large precursor. We also show that in a RNaseP⁻ strain[8] the $tRNA^{Tyr}$ precursor is cleaved incorrectly by an specific nuclease.

Mutations in the *sup*3 gene

The phage φ80*psup*3 (Kyoto) carries both the suppressor and the wild-type $tRNA_1^{Tyr}$ genes. We have studied the expression of the two genes in cells infected with the original phage and with five mutants: A1, A2, U80, U81 and G82. These mutants have been previously described[6], each contains a single base change in the amino acid acceptor stem of the suppressor tRNA. The A1 mutation results in a G→A base substitution at the 5′ end of the suppressor tRNA. Three independently isolated φ80*psup*3 A1 mutants (A1·16, A1·56 and A1·79) were compared with φ80*psup*3 (Kyoto) for the expression of the suppressor and the wild-type $tRNA^{Tyr}$ genes. The total RNA synthesised after infection with the transducing phages was labelled with ^{32}P-orthophosphate and subjected to polyacrylamide gel electrophoresis[9] which separates the total $tRNA^{Tyr}$ from other tRNAs, most of which migrate as a broad band running ahead of the $tRNA^{Tyr}$ band ('4S' tRNA).

The total tyrosine tRNA corresponds to a mixture of suppressor $tRNA_1^{Tyr}$, wild-type $tRNA_1^{Tyr}$ and host $tRNA_2^{Tyr}$. The ratio (total $tRNA^{Tyr}$)/('4S' tRNA) was calculated by direct counting of the two bands. The quantitative estimation of the various types of $tRNA^{Tyr}$ was carried out as described in the legend of Table 1. The results are presented in Table 1, lines 1 to 4. Columns I to V show the ratio of total $tRNA^{Tyr}$

Table 1 $tRNA^{Tyr}$ production in A1 infected cells

$tRNA^{Tyr}$ production in A1 infected cells. *E. coli* MB94 grown in low phosphate medium[19] at 30° C was infected at a multiplicity of 30 and labelled for 60 min with ^{32}P-orthophosphate[19,20]. The total RNA was subjected to polyacrylamide gel electrophoresis[9]. The ratio (total $tRNA^{Tyr}$)/('4S' tRNA) was determined by direct counting of the two bands. The total $tRNA^{Tyr}$ was extracted from the gels, digested with T_1 RNase and subjected to two-dimensional electrophoresis[11,12]. Since all the mutants give characteristic T_1 fragments[6], it is possible to determine the proportion of mutant and wild-type tRNA among the total $tRNA^{Tyr}$. Similarly, the proportion of host $tRNA_2^{Tyr}$ can be determined since it contains the hexanucleotide UCACAG which is not present in $tRNA_1^{Tyr}$ (ref. 10). Columns I to V show the ratio of the radioactivity present in the total $tRNA^{Tyr}$ to that in the 4S tRNA in five experiments. The radioactivity of the various T_1 fragments was measured by liquid scintillation counting.

* The mutant 3′ end has the C→ U81 base substitution.
† A1.16, A1.56 and A1.79 are three independent isolated A1 mutants.
‡ Average result of two independent determinations.
§ The same results are obtained in uninfected cells or Φ80 infected cells.
– Absence of the fragment.
ND Not determined.

Table 2 Expression of the $tRNA^{Tyr}$ genes

Mutant	*Phage-coded $tRNA^{Tyr}$ (%) 4S tRNA	Coefficient of expression of the $tRNA^{Tyr}$ genes Total†	Wild-type gene‡	Suppressor gene‡
Single mutants				
A1·16, A1·56, A1·79	25	0·23	0·20	0·02
*sup*3	109	1·0	0·5	0·5
Double mutants				
A1·16 U81	107	0·98	0·55	0·45
A1·16 P2, A1·56 P2	60	0·55	0·325	0·225

* The average ratio tyr tRNA/4S tRNA was calculated from the data in Table 1 and the background of host tyrosine tRNA has been subtracted.
† The full expression of both genes has been given value a of 1 (*sup*3).
‡ The values correspond to the ratio wild-type: suppressor found as result of the T_1 RNase digestion. The efficiency of transfer of the pAG fragment to the DEAE-cellulose paper is 90%; therefore a factor of 1.1 was applied to convert the molar yields of pAG into the ratios A1 tRNA: total $tRNA^{Tyr}$. The efficiency of transfer of the normal and modified 3′ ends were assumed to be identical.

to the bulk of other tRNAs ('4S' tRNA) in five experiments. The last column shows the molar yield of the T_1 RNase fragments pAG (characteristic of the A1 tRNA) and UCACAG (characteristic of $tRNA_2^{Tyr}$ (ref. 10). The results of all three A1 mutants have been pooled in Table 2, column 1. In the second column the average ratio (total $tRNA^{Tyr}$)/('4S' tRNA) is expressed as a function of the average ratio for φ80*psup*3 (Kyoto). This fraction represents the 'coefficient of expression' of the transduced $tRNA^{Tyr}$ genes, equal to 1 in the case of *sup*3 (Kyoto) were both genes are normally expressed. In the last two columns of Table 2 the 'coefficient of expression' is distributed between the wild-type and the suppressor genes according to the relative proportions of the two tRNAs revealed by T_1 RNase digestion. The results show that the A1 mutation reduces the expression of the adjacent wild-type gene to 40% of its normal value. This effect is *cis* specific since the amount of $tRNA_2^{Tyr}$ is not reduced after infection by any of the A1 mutants. The A2 mutation (G→A change at the second position from the 5′ end) reduces the amount of suppressor tRNA to 25-30% and the amount of wild-type tRNA to 70-75% of their normal value (data not shown). The U80, U81 and G82 mutants synthesise both tRNAs at normal levels (data not shown).

Reversion of the effect of A1 and A2 by secondary mutations

Double mutants showing an increased suppressor tRNA synthesis have been isolated from φ80*psup*3 A1 (Kyoto)[6]. One of them, A1U81, has a second base change at position 81, opposite to position 1 in the clover-leaf structure, while the second (A1P2) has no other change in the nucleotide sequence of the mature tRNA. One A1U81 and two independent A1P2 mutants were studied. The $tRNA^{Tyr}$ production in infected cells are reported in Table 1, lines 5-7. The data has been treated as described above and summarised in Table 2. The U81 mutation raises the amount of the suppressor tRNA to almost normal levels. In addition U81 fully reverses the effect of the A1 mutation on the production of the wild-type tRNA. This indicates that the effects of the A1 mutation on the amounts of the suppressor and of the wild-type tRNAs are due to the same structural defect which is corrected by the second C→U81 base change. The P2 mutation also reverses the effect of A1 on both suppressor and wild-type tRNA production, however this reversion is only partial. P2 does not seem to be a promoter mutation since it induces different increases in the coefficient of expression of the two tRNAs. Therefore P2 is most likely a precursor mutation which somehow compensates for the structural defect caused by the A1 mutation. A double mutant, A2U80, obtained from φ80*psup*3 A2(Kyoto)[6] has also been studied. The secondary C→U mutation at position 80 completely reverses the effect of A2 on the synthesis of the suppressor and the wild-type tRNAs (data not shown).

$tRNA^{Tyr}$ precursors in RNase P⁻ cells

To characterise the transcription products of the phage-transduced $tRNA^{Tyr}$ genes we used the temperature-sensitive RNase P⁻ mutant described by Schedl and Primakoff.[8] At 42° C the tRNA-processing enzyme RNase P is inactive, thus allowing the isolation of tRNA precursors in which the 5′ termini has not been removed. We analysed the RNAs

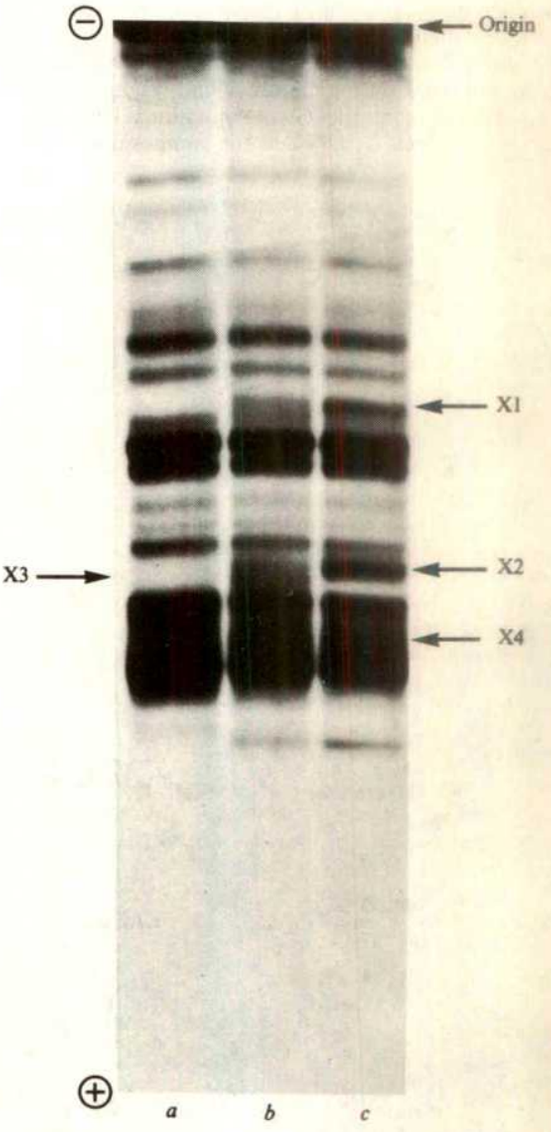

Fig. 1 Polyacrylamide gel electrophoresis of ^{32}P–RNAs from A49 infected cells. A49 cells (RNase P⁻, kindly provided by P. Schedl) grown at 30° C in TPGA medium[21] (5×10^{-4} M phosphate) to 4×10^{8} cells ml^{-1} were collected by centrifugation and re-suspended in one-fifth volume of TPGA medium (5×10^{-5} M phosphate) prewarmed at 42° C. After 10 min of aeration at 42° C, 0.02 vol of M $MgSO_4$ was added and 0.5 ml of cells were infected at a multiplicity of 30. After 10 min adsorption without aeration the cells were diluted 10-fold into TPGA medium (5×10^{-5} M phosphate) prewarmed at 42° C ($t=0$). 5 mCi of ^{32}P–orthophosphate were added at $t=27$ min and the incorporation stopped 10 min later by adding and equal volume of buffer saturated phenol prewarmed at 42° C. This procedure is similar to that described by Schedl and Primakoff[8]. Radioactive samples were applied to 12% polyacrylamide gels as described by Peacock and Dingman.[9] a, φ80; b, φ80 *psup* 3 A1U81 (Kyoto) and c, φ80 *psup* 3 (Cambridge).

synthesised in RNase P deficient cells infected with φ80*psup*3 (Kyoto), φ80*psup*3 (Cambridge) and various mutants. Figure 1 shows an autoradiograph of a polyacrylamide gel electrophoresis of ^{32}P-RNAs from RNase P$^-$ cells infected with (*a*) φ80, (*b*) φ80*p sup*3 A1U81 (Kyoto) and (*c*) φ80*psup*3 (Cambridge) and labelled with ^{32}P-orthophosphate at 42° C. Bands X1, X2, X3 and X4 are absent from cells infected with φ80 and all contain tRNA^{Tyr} sequences. The pattern of RNAs synthesised after infection with φ80*psup*3 (Kyoto) is identical to that from φ80*psup*3 A1U81 (Kyoto). All the bands were extracted from the gels, digested with RNase T_1 and fingerprinted[11,12]. The results for A1U81 are shown in Fig. 2. X1 corresponds to the precursor tRNA described by Altman and Smith[4]. It contains the sequence of precursor A1U81 *sup*3 tRNA, however, and not that of the wild-type tRNA$_1^{Tyr}$ precursor (Fig. 1*a*). The 3′-end fragment of this precursor was shown by pancreatic RNAse digestion to contain the C→U81 base change. It also contains a few additional 3′ nucleotides (including the dinucleotide AU) which are not found in the mature 3′-end fragment. The UAG fragment results from the G→A mutation. The absence of C81-modified 3′ end, ACUG and the composition of the anticodon indicate that no wild-type tRNA sequence is present in this RNA band.

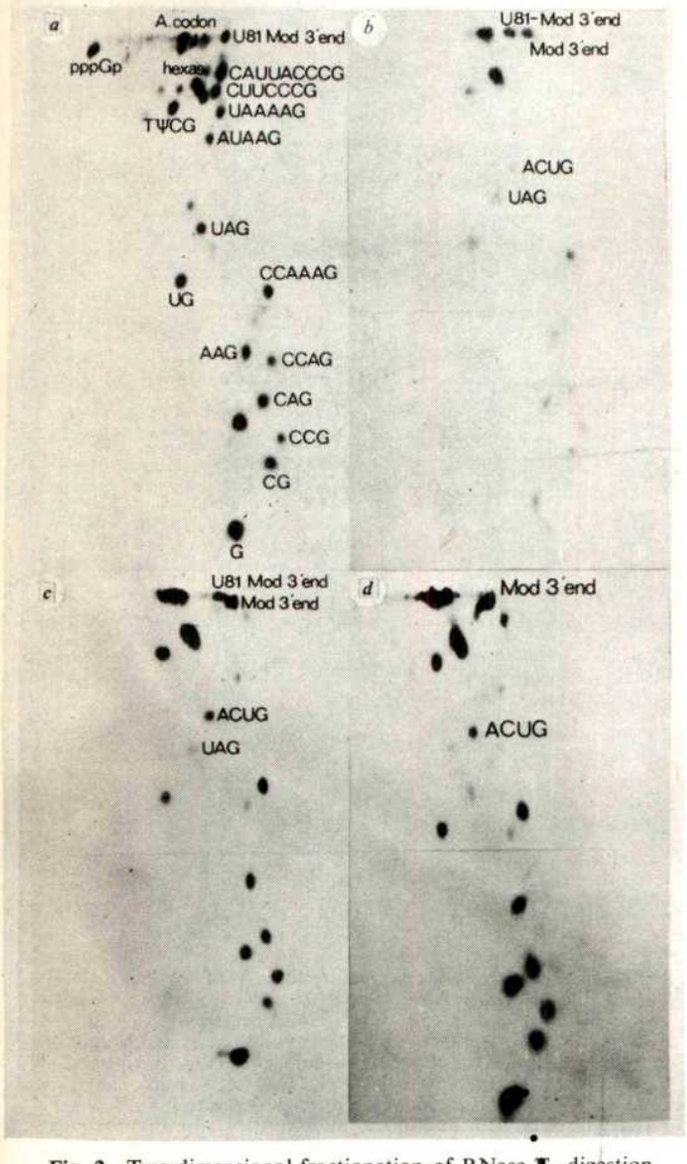

Fig. 2 Two-dimensional fractionation of RNase T_1 digestion products. *a*, A1U81 band XI; *b*, A1U81 band X2; *c*, A1U81 band X3 and *d*, A155P2 band X3. Electrophoresis on cellulose acetate in pyridine acetate, 7 M urea, *p*H 3.5 right to left; and on DEAE paper in 7% formic acid (v/v) from top to bottom. U81–Mod 3′ end=3′-end fragment containing the U81 mutation and the extra 3′ end nucleotides. Mod 3′ end=3′ end fragment containing the 3′-end extra nucleotides.

Band X2 (Fig. 2*b*) corresponds to a 1:1 mixture of A1U81 and wild-type sequences as judged by the quantitation of the two 3′-end fragments (containing U81 and C81 respectively), ACUG and the anticodon fragment. None of the fragments of the precursor 5′ end can be detected, yet these tRNAs differ from the mature tRNAs in the absence of the normal T_1 5′-end fragments (pAG and pGp respectively). In the case of the suppressor tRNA pAG is replaced by a new 5′-end fragment, UAG. This fragment results from the incorrect cleavage of the precursor between residues 40 and 41 (ref. 4) as shown in Fig. 3. Also, pancreatic RNase digestion of band X2 tRNA gives AGU and no pAGU can be detected. The situation however is not clear for the wild-type tRNA^{Tyr} since we do not find any new fragment that replaces pGp. The 3′ end of both tRNAs contain some or all of the 3′-end extra nucleotides present at the 3′ end of band X1 RNA.

Band X3 (Fig. 2*c*) corresponds to a 1:2 mixture of A1U81 and wild-type sequences; no other difference could be detected between the fingerprints of bands X2 and X3. These bands do not always separate; the occasional separation could conceivably be due to a partial loss of some of the 3′-end extra nucleotides.

Band X4 RNA (fingerprint not shown) differs from band X2 and X3 by having mature 3′-end fragments. Since this band is heavily contaiminated and the fingerprints contain pGp it is difficult to assess whether the wild-type tRNA has an abnormal 5′ end. In the case of the suppressor gene we can detect small amounts of pAG, however this fragment is not in molar yields with the U81 3′-end fragment. It is likely then that at least the suppressor tRNA contains an abnormal 5′ end.

Although we analysed all the other bands in the gel in Fig. 1*b*, we have been unable to find a precursor for the wild-type tRNA or a doublet precursor. Further evidence that a singlet precursor for the wild-type tRNA gene cannot be detected has been obtained by analysing the RNAs synthesised in RNase P$^-$ cells infected with A1 mutants. Infection with φ80*psup*3 A1 (Cambridge), which carries only the A1 tRNA gene, yields none of the 1 to 4 bands as a result of the thermosensitivity of the A1 mutation. When the infecting phage is φ80*psup*3 A1P2 (Kyoto), which carries both the A1 and the wild-type genes, only bands X3 and X4 can be detected (results not shown). T_1 RNase digests of band X3 (Fig. 2*d*) and X4 (not shown) confirm that they contain the wild type but not the A1 sequence. Similar analysis of the φ80*psup*3$^-$ phage (Cambridge) which carries only the wild-type gene yields bands X1, a diffuse band in the position of X2 and X3 and band X4 (results not shown).

Common tRNA precursor

Some mutations, which break base pairs in the amino acid acceptor stem of the suppressor tRNA$_1^{Tyr}$ decrease the yield of tRNA coded by the adjacent wild-type gene. This result suggests that the two tRNAs are synthesised as a single transcription product ('doublet' precursor), so that a structural deformation close to the RNase P cleavage point affects the processing, and therefore the yield of both tRNAs. This explanation is further supported by the observation that no 'singlet' precursor can be detected for the wild-type tRNA^{Tyr}. We feel that the origin of the tyrosine tRNAs sequence found in RNase P$^-$ cells is best explained as pictured in Fig. 3. The two genes are transcribed as a long precursor containing both sequences, the suppressor sequence being first from the 5′ end. The length of the spacer between the two tRNAs cannot be derived from our data, it could be 35-70 nucleotides[13]. As a result of endonuclease cleavage(s), this unstable precursor yields a singlet precursor containing the suppressor sequence (band X1), and a wild-type tRNA with inmature 5′ and 3′ ends (bands X2 and X3). The 'singlet' precursor is further cleaved incorrectly but specifically between residues 40 and 41 of the

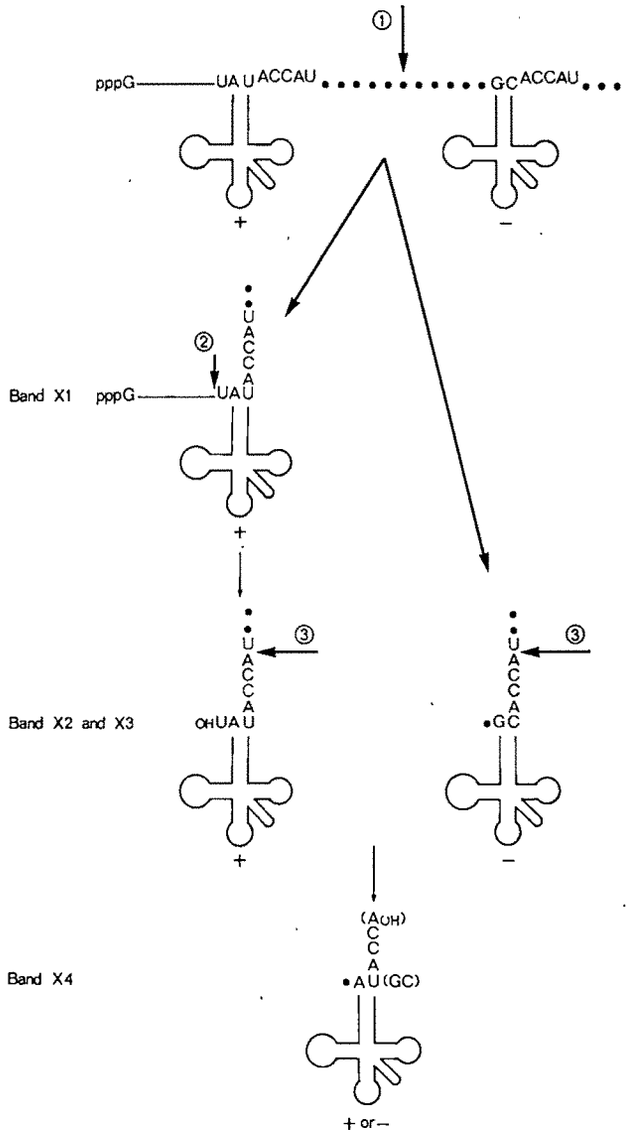

Fig. 3 Possible origin of the precursor cleavage products. The first tRNA sequence of the doublet precursor corresponds to the A1U81 suppressor, the second is the wild-type sequence. The black dots indicate that neither the length nor the sequence of these fragments is known. The arrows indicate the proposed nuclease cleavage. The last residue of the 'mature' tRNA has been written as (A_{OH}) since we have not established its identity. + and − correspond to the suppressor and wild-type anticodon respectively.

precursor fragment[4] (arrow 2 in Fig. 3) to give a suppressor tRNA beginning with HOUAG – – – – at the 5′ end and with immature 3′ end. At present we do not know whether the enzyme that cleaves incorrectly at the 5′ end of the suppressor tRNA is also responsible for the cleavage of the initial doublet precursor at the 5′ end of the wild-type tRNA. Finally, the extra 3′ end nucleotides are cleaved (arrow 3 in Fig. 3). At least in the case of the suppressor tRNA the 5′ end seems to remain abnormal.

Another example of common precursor for closely linked tRNA genes has been reported in the case of the T4 coded tRNAs[14,15]. Furthermore the occurrence of other closely linked tRNA genes in the bacterial genome also raises the possibility of large bacterial tRNA precursors containing two or more tRNA sequences[16–18]. Indeed, Schedl and Primakoff[8] have recently reported that they have found tRNA precursors containing more than one tRNA sequence in RNase P⁻ cells.

We thank Drs John D. Smith, C. C. Allende and J. E. Allende for discussion and reading the manuscript. M. D. Squire provided expert technical assistance. A. G. was supported by fellowships from the Ford Foundation (Santiago), the European Molecular Biology Organisation and the Fonds National de la Recherche Scientifique (Cambridge).

Simian virus 40 in a human cancer

Federico Soriano, Charles E. Shelburne & Muharrem Gökcen

Research and Education Division, Health Central Inc. & Life Sciences Foundation, Minneapolis, Minnesota 55422

Simian virus 40 (SV40) and SV40 T (tumour) antigen have been detected in the malignant melanoma metastases of a patient in which specific viral and T antibodies were demonstrated.

THE patient in our investigation, a plumber born in 1894, had no personal or familial history of chronic illness or congenital anomaly. A pigmented skin growth in his upper back, which he had noticed 2–3 yr before, was removed in 1964 and found to be a malignant melanoma. The diagnosis

was later confirmed in biopsies of axillary and cervical lymph node metastases, in the cells of a pleural exudate that developed shortly before death, and at autopsy, performed in December 1967. No history of immunisation with vaccines likely to contain SV40 was later found. At autopsy there were widespread pigmented or unpigmented metastases in the skin and muscles of the shoulder and chest wall, in the lungs, pleuras, diaphragm, liver, lymph nodes, dura, brain and heart, also hydrothorax and bronchopneumonia.

The medium used for tissue culture consisted of equal parts of McCoy's 5a medium and medium 199, supplemented with foetal bovine serum and antibiotics. Metastatic and normal tissues taken at autopsy were cultured after mincing or trypsinising. The tumour cultures initially contained tumour cells, fibroblasts and some lymphocytes. All cultures were kept for 1–3 months but were gradually lost. Only cultures of normal spleen and normal kidney were frozen for future subculture; none of the others showed adequate growth. Continuous cultures of typical lymphoblastoid cells forming floating colonies eventually emerged from cultures of the spleen and of muscle and lymph node metastases, however. These three exclusively lymphoblastoid cell lines have been cultured for several years.

Virus studies

Several specimens of lung, liver and muscle metastases and of normal spleen and kidney had been frozen since autopsy at −94°C without medium or cryoprotective agents. Beginning 14 months after autopsy, the specimens were thawed, minced, forced through fine sieves while rinsing, centrifuged, and resuspended at 20% concentration in medium containing 10% heated foetal bovine serum. Aliquots were frozen for future use. The suspensions consisted of broken cells and debris. They were centrifuged at 500*g* for 10 min and each of several monolayers grown in 30-ml flasks was inoculated with 0.1 ml of the pellet. The cultures were maintained with medium containing heated foetal bovine serum and examined regularly with an inverted phase contrast microscope.

In the first isolation experiment with various human and animal cell cultures, signs of cytopathic effects characteristic of SV40 were first observed after 30 d in one primary grivet (African green monkey) kidney culture inoculated with a lung metastasis specimen. Ten days later virus was collected (isolate A). All cultures had been observed for more than 1 month before inoculation and were negative for virus and *Mycoplasma*. All negative and control cultures were held for 6 weeks after virus collection; no virus growth occurred.

To avoid the risk of viral contamination in new lots, primary grivet kidney cultures were permanently discontinued after this experiment; primary rhesus kidney cultures were never used. Subsequent isolations were carried out with the grivet kidney-derived BSC-1 cell line; cell stock was obtained from the American Type Culture Collection. From another lung metastasis virus was recovered in three further successive attempts (isolates B, C and D). In two other separate experiments virus was isolated from liver and muscle metastases (isolates E and F). In no case was any incipient cytopathic effect characteristic of SV40 observed sooner than the fourth week of incubation or later than the fifth. In each experiment all negative cultures and controls were kept, without showing cytopathic effects, for at least 8 weeks after virus collection from the positive cultures. Over the years during which these isolations were made no viral or mycoplasmal contamination was detected in several thousand stock and control cultures monitored periodically by electron microscopy or cultural methods.

Several other attempts with the previously positive specimens or with different tumour specimens were unsuccessful. Virus was recovered from about 3% of approximately 500 cultures inoculated with original tumour tissue pellets or with blind passages. In the successful isolations, excluding the other attempts, a total of 11 ml of packed tissues (0.1 ml per culture) yielded 15 positive cultures. It can be estimated that approximately 1 infectious unit was contained in 1 g of the pellets or in no less than 1 g of intact tumour at the time of death, and that virus was detectable only in some parts of the tumours.

In further experiments inoculation of tumour pellets into less sensitive grivet kidney cell lines (CV–1, Vero) yielded no virus and BSC–1 cultures remained negative after inoculation with cell-free tumour extracts. No virus was recovered from BSC–1 cells inoculated with pellets of the normal spleen and normal kidney, nor from human fibroblast and primary embryonic kidney cultures inoculated with pellets of the tumours or of the normal organs. No virus grew, and no viral or T antigen was detected by immunofluorescence, in BSC–1 cultures inoculated with live (cocultivation) or homogenised cells of the three lymphoblastoid lines. Each of these experiments lasted 2–3 months and was repeated at least once.

Electron microscopy of a brain metastasis that had been kept in formalin revealed no virions in several samples of the tumour and of the adjacent white matter. There was good preservation of fine detail.

Mice and Syrian hamsters were inoculated at birth with pellets of the normal and metastatic tissues and of pleural tumour cells obtained before death. No meaningful disease occurred during the natural life span of the survivors.

In cross-neutralisation tests no significant differences were found between the six isolates and two known SV40 strains. Strain J436 and baboon antiserum to J436 were obtained from the National Institutes of Health, strain A2895 from the American Type Culture Collection; rabbit antisera to A2895 and to the six isolates were produced in our laboratory. The two known antisera neutralised the six isolates and two known strains to the same extent; antiserum to each isolate had about the same titre against the particular isolate as against the two known strains. Since each isolate was also proved to be oncogenic for newborn hamsters and no difference from SV40 was found in further work, we have designated isolates A to F collectively as Strain F of SV40, or SF.

Strain F is identical to other strains in its intrinsic properties, growth in cell cultures, cytopathic effects, cell-transforming efficiency, oncogenicity, and electron microscopic features[1–4]. Subcutaneous or intracerebral inoculation of newborn hamsters induced local sarcomas or ependymomas as described for SV40 (refs 5 and 6). Cultures of non-tumour human cells supported its growth and underwent malignant transformation. Inoculation of SF-transformed mouse or hamster cell cultures in the respective hosts resulted in malignant tumours. As within SV40 strains, tumours can be prevented in hamsters inoculated at birth with strain A2895 by injecting SF during the incubation period; conversely, SF tumours can be prevented by a second injection with A2895.

Identity of the cellular T antigen induced by SV40 (ref. 7) with the SF-induced T antigen was demonstrated by indirect immunofluorescence[8]. Coverslip cell cultures fixed in acetone were used immediately or stored at −30° C. Known SV40 T-positive cultures were TT–101, a virus-free SV40 hamster tumour cell line (Flow Laboratories, Rockville, Maryland) and BSC–1 cells inoculated with A2895; SF T-positive cultures were S–419, a virus-free line derived from an SF hamster tumour, and BSC–1 cells inoculated with SF. Infected BSC–1 cells were fixed 3 d after inoculation. Control cultures were normal continuous (BHK–21) or primary hamster kidney cells, and normal BSC–1 cells. Known SV40

T antiserum was obtained from Flow Laboratories and from hamsters bearing transplanted A2895 tumours, SF T antiserum from hamsters with transplanted SF tumours, and control serum from normal hamsters; all T antisera were free of viral antibodies. Fluorescein-labelled γ-globulin against hamster γ-globulin was obtained commercially. The SV40 T antisera stained SV40 T-positive and SF T-positive cells to the same extent, and the same was true for the SF T antiserum; all controls were negative. Each antiserum was absorbed equally well with T antigen extracts from hamster tumours induced by known SV40 or SF.

Antibody and antigen studies

Patient's serum was unavailable, but several specimens of pleural exudate had been stored at −30° C. Early attempts to demonstrate antibodies in exudate obtained shortly before death were unsuccessful. The patient's blood belonged to group O, however, so a search for samples with at least agglutinating antibodies for AB erythrocytes was made. Only the earliest sample, stored 6 d before death, had haemagglutinating activity. It contained IgG, IgA, IgM, and detectable SV40 viral and T antibodies.

Heat-inactivated exudate, diluted 1:2, neutralised 70–100 median tissue culture infectious doses of SF, A2895 or J436 in BSC–1 cells observed over 3 weeks but it did not do so when diluted 1:2 in a concentrated rabbit γ-globulin of a high titre against human γ-globulin, thus indicating activity caused by antibody. The antihuman γ-globulin alone had no effect on the viruses or the cells.

T antibodies were demonstrated as described above by indirect immunofluorescence with known SV40 T-positive cultures (virus-free TT101 cells and A2895-inoculated BSC–1 cells), SF T-positive cultures (virus-free S–419 cells and SF-inoculated BSC–1 cells) and controls. To prevent virus growth, inoculated BSC–1 cultures were maintained during the 3 d of incubation with daily changes of medium containing 20 μg ml^{-1} 5-fluorodeoxyuridine and 20 μg ml^{-1} 1-β-D-arabinofuranosylcytosine. Besides normal BSC–1 and hamster cells, controls included previously T-positive coverslips in which the antigen had been destroyed by storing for several weeks at 4° C and positive controls stained with hamster T antiserum and labelled anti-hamster γ-globulin. The exudate was treated with heparin to inhibit any solublisation of T antigen by RNase it may have contained, and with thimerosal and phenol to inhibit microbial growth. Normal human serum and the labelled globulin applied alone served as controls. The exudate stained typically and exclusively the nuclei of all T-positive cells. Six applications, each followed by 1 d of incubation at 4° C, were needed for best results with the tumour cells. Quicker results were obtained with inoculated BSC–1 cells, which produce more antigen, and with exudate concentrated by ammonium sulphate precipitation. Concentrated exudate absorbed with T antigen extracted from BSC–1 cells infected with SF or A2895 lost its staining activity, but it did not when absorbed with the same extracts previously exposed—after sterilising by filtration—to 'warm' temperatures, that is, to 4° C for several weeks or 22° C for a few days, or when absorbed with normal BSC–1 extracts. Concentrated exudate blocked the binding of fluorescein-labelled hamster T antiserum to T-positive BSC–1 cells, as judged by a conspicuous reduction of the staining intensity. Normal human serum and high titre anti-nuclear sera from patients with systemic lupus erythematosus had no effect.

T antigen was demonstrated in the patient's tumour tissue suspensions. These were sonicated, treated with RNase and centrifuged. The antigen was precipitated from the supernatants with saturated ammonium sulphate (32%) or by acidifying to *p*H 5 with 0.2 M acetic acid[9]. The precipitated antigen was redissolved and dialysed in phosphate-buffered saline, *p*H 7.2. With the small amounts involved little final concentration—but some purification—was achieved. For positive control, an SF hamster tumour that had been kept frozen was extracted in the same way after homogenising. These extracts served also as negative controls after exposure to warm temperatures to destroy the antigen, as described above (inactivated T antigens). Similar extracts from a human placenta and a human myoma were additional control antigens.

A solid-phase microradioimmunoassay[10] was adapted to demonstrate T antigen. Serial two-fold dilutions of antigens in phosphate-buffered saline were placed in wells of microtitre plates, 25 μl per well, and dried at 4° C under vacuum in a desiccator containing calcium sulphate. After methanol fixation the plates were rinsed with buffered saline, and 20 μl per well of each appropriate serum or γ-globulin were successively applied for 1 h at 22° C. The plates were rinsed after each step; the final γ-globulin against hamster or human γ-globulin was labelled with ^{125}I (^{125}I-γ-globulin). The wells were then cut out, placed in tubes and counted for radioactivity in a γ spectrometer. The average c.p.m. bound to triplicate test wells divided by the average c.p.m. bound to control wells gave the binding ratio, ratios of 1.5 or greater

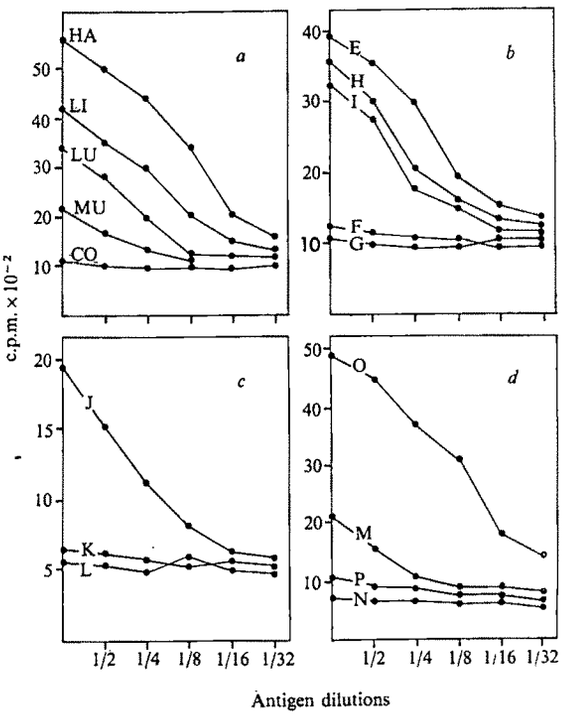

Fig. 1 Radioimmunoassays of the patient's T antigen and antibodies. *a*, Liver (LI), lung (LU) and muscle (MU) tumour antigen extracts; a negative control (CO); an SV40 hamster tumour extract (HA) as a positive control. All reacted with hamster T antiserum and anti-hamster ^{125}I-γ-globulin. The following tests were performed with the patient's liver tumor antigen with a titre of 16. *b*, Absorptions: hamster T antiserum, unabsorbed (E) or absorbed with the patient's T antigen (F), hamster T antigen (G), inactivated patient's T antigen (H) or placenta antigen (I), followed by anti-hamster ^{125}I-γ-globulin. *c*, Antibodies: patient's exudate (J), normal human serum (K) or systemic lupus erythematosus serum (L) followed by anti-human ^{125}I-γ-globulin. *d*, Blocking tests: normal hamster serum (M) or hamster T antiserum (N), both followed by exudate and anti-human ^{125}I-γ-globulin; normal human serum (O) or exudate (P), both followed by hamster T antiserum and antihamster ^{125}I-γ-globulin. (For details see text.)

being taken as significant. The titre was the reciprocal of the highest dilution giving significant binding.

The T antigen titres obtained with hamster T antiserum and anti-hamster ^{125}I-γ-globulin in the extracts of the patient's metastases and of the hamster tumour are shown in Fig. 1*a*. The differences in titre are considered irrelevant. The suspensions of metastases from which the extracts were made had been thawed and rewarmed several times for various periods of time; the hamster tumour had never been used; the muscle specimen contained many normal muscle fibres. The placenta and myoma extracts and the inactivated T antigens gave approximately similar results, no different from the background given by the labelled globulin alone; a representative curve is shown. The following assays were performed with the liver tumour extract with a titre of 16 (patient's T antigen). T antibodies were removed from the hamster T antiserum by absorption with patient's or hamster T antigen but not with inactivated patient's T antigen or placenta extract (Fig. 1*b*). The specificity of the patient's T antigen and antibodies was further demonstrated. The patient's exudate bound significantly to the patient's T antigen but normal human serum or high titre anti-nuclear serum from patients with systemic lupus erythematosus did not (Fig. 1*c*). In blocking tests, hamster T antiserum and exudate inhibited the binding of each other to the patient's T antigen but lupus and normal human serum or normal hamster serum had no effect (Fig. 1*d*).

No viral or T antigen was detected by this method or by immunofluorescence in the three lymphoblastoid cell lines derived from metastatic tissues and from the normal spleen, nor by immunofluorescence in subcultures of the normal renal epithelium or of the splenic mixture of fibroblasts, macrophages and lymphoid cells.

SV40 in humans

The findings in this case correspond to those in hamsters with SV40 tumours. Virus and T antigen were detected in lung, liver and muscle metastases but not in the normal spleen and kidney or in the three lymphoblastoid cell lines; viral and T antibodies could still be detected in the dying patient.

Not much is known about SV40 multiplication in humans. It has rarely been isolated: from faeces after ingestion[11], from throat swabs after respiratory route inoculation[12], and from the brains of two patients with progressive multifocal leukoencephalopathy[13]. Only human cells are truly semipermissive *in vitro*, both undergoing transformation and permitting SV40 growth. Normally, monkey cells are only permissive, and hamster or other animal cells are nonpermissive, that is, can only be transformed. Although humans are apparently inefficient hosts[14], initial *in vivo* growth, sufficient to induce viral (but not anti-T) antibody, is inferred from the titres in persons infected by the respiratory[12] or subcutaneous[15] route, in monkey handlers and in persons (including some cancer patients) with no known SV40 contact[14]; this last group suggests a natural infection from an unknown reservoir and by an unknown route[14].

The minute amounts of SV40 detected exclusively in the patient's tumours could not alone account for a viral antibody response, and do not suggest virus growth but the well known occasional release of minimal residual infectivity by some nonlysing malignant cells. Moreover, since no differences in susceptibility of any human cells for SV40 infection are known, it is very unlikely that this tumorigenic virus could be fortuitously present in three different tumorous organs but not in the normal ones.

The presence of readily detectable T antigen in the tumour extracts cannot be explained by local virus growth. In infected monkey organs SV40 proliferates optimally but individual T-containing cells could not be detected[16]. As well as high anti-viral titres the animals can develop T antibody[16], so the innocuously infected monkey tissues must release immunogenic but *in vivo* probably undetectable amounts of T antigen. By contrast, T antibodies have not been detected in noncancerous persons with high and persistent anti-viral titres[14,15,17]. Some reactivity with SV40 T antigen has been detected in only three cancer-free persons who had insignificant or no SV40 anti-viral activity; it must be considered to be caused by cross-reacting antibodies directed against an antigen produced by BK virus, a different agent[17]. The failure to detect T antibody in many cancer patients[14] may indicate that there are indeed very few SV40 tumours, or that therapy prevented the tumours becoming very large and partly necrotic and releasing the intranuclear antigen[18]. Failure may also be a consequence of the fact that the antibody levels present may be detectable only by more sensitive techniques, or of immunosuppression by anticancer drugs or irradiation.

We have not detected T antigen in other melanomas; the evidence does not imply any obligate association of human malignant melanomas with SV40. Injected intravenously, SV40 can cause leukaemia, lymphosarcoma, reticulum cell sarcoma, osteogenic sarcoma and possibly other malignancies in hamsters[18]. Viral antibodies, and by inference SV40 infection, occur in childhood[14]. Human SV40 malignancies may conceivably[19] develop only occasionally after a very long time or fortuitous triggering. The possibility of SV40 hybridising *in vivo* or *in vitro* with other viruses must be considered, for hybrids could spread the tumour-inducing genes of SV40 more efficiently than the pure virus; the adenovirus–SV40 hybrids that have originated *in vitro* are well known.

SV40 tumour cells, like all other cells permanently transformed by SV40, contain without exception specific T antigen, a nonviral marker of unknown function that indicates integration of the viral into the cellular genome[7,19]. No systematic search for SV40 T antigen in human cancers has been made. Confirmation of the oncogenicity of SV40 for humans will have to come from finding additional cases, especially by T antigen detection.

Outline structure of cytochrome c_3 and consideration of its properties

C. M. Dobson, N. J. Hoyle, C. F. Geraldes, P. E. Wright & R. J. P. Williams

Inorganic Chemistry Laboratory, Oxford, UK

Laboratoire de Chimie Bacterienne, CNRS, Marseille, France

An outline structure of cytochrome c_3 from Desulfovibrio vulgaris *has been deducted from sequence and nuclear magnetic resonance data. From this structure conclusions about electron transfer processes have been drawn*

THE cytochromes of the c_3 and c_7 groups form a class of multihaem proteins found in certain bacteria[1,2]. From the reaction chains in which they are involved these proteins seem to serve electron transfer and storage functions much in the same way as do the ferredoxins. As is true of many ferredoxins these cytochromes have more than one redox centre (here haem), are of low molecular weight, and have a low redox potential. Great interest centres in their structures and electron transfer reactions. Here we shall give an outline structure of one such protein, cytochrome c_3 from *Desulfovibrio vulgaris* and go on to describe its electron transfer properties. Information about the outline structure has been deduced from a knowledge of the amino acid sequence, and the nuclear magnetic resonance, the absorption, and the electron spin resonance spectra, studied under a variety of conditions. It should be understood that in principle the structure can be improved so as to produce a full three dimensional map by the methods we have described elsewhere[3–5], but that this procedure is totally different from that used in an X-ray crystallographic series of refinement. In crystallography a rough three-dimensional density map is improved by increasing data input until local molecular configuration can be discerned. The methods which we use start from local knowledge and build up to the full three-dimensional structure using many cross checks. Thus we shall proceed in this paper from a one-dimensional sequence to a trial outline three-dimensional structure. This outline structure is being thoroughly tested. While gathering structural information by NMR much is learnt about the dynamic properties of the protein.

The sequences of five cytochromes of the c_3 and c_7 classes are known. These sequences, including that of *Desulfovibrio vulgaris*, are given in Table 1 (ref. 2). The number of haem residues thought to be bound is four in all cases except that of cytochrome c_7 of *Chloropseudomonas ethylica*. The groupings Cys-*x*-*x*-Cys-His and Cys-*x*-*x*-*x*-*x*-Cys-His where *x* represents an amino acid are obvious haem binding sites, the histidine binding to the iron (compare cytochrome *c*). Haem binding groups in addition to the above cysteine sequences which have been found in other proteins are histidine (cytochrome b_5) methionine (cytochrome *c*) and water (myoglobin). We cannot however exclude a lysine or a carboxylate-containing residue as an iron binding group. The sequences by themselves do not therefore define such groups although some further clues are available from them. There are a further four invariant histidines (33, 36, 47 and 83), apart from those indicated above (46, 64, 97 and 122), in the sequences of the four cytochromes c_3 which have four haems. Close to these histidines lie aromatic amino acids which might be expected to be associated with a haem pocket. (Note these are such small proteins that they have only just enough amino acids to cover the four haem residues, for each haem residue requires about 20 amino acids to cover it.) The sequences also contain invariant lysine residues which could well neutralise the anionic carboxylate groups of the haem residues. It is notable too that certain parts of the sequences are very variable such as between residues 0-25, and 99-108. Much of the region from residues 55 to 90 is missing in the three-haem protein from *Chloropseudomonas ethylica*. This region includes the cysteine sequences 58-64 and also histidine 47. This indicates that these are the binding groups of one haem in the four-haem cytochromes c_3.

Table 1 Amino acid sequences of cytochromes c_3 and c_7.

* *Desulfovibrio gigas* NCIB 9332 (c_3)
† *Desulfovibrio vulgaris* MCIB 8303 (Hildenborough) (c_3)
‡ *Desulfovibrio desulfuricans* MCIB 8380 (El Agheila Z)(c_3)
§ *Desulfovibrio salexigens* NCIB 8403 (British Guiana) (c_3)
¶ *Chloropseudomonas ethylica* (c_7)
Sequence § (*D. salexigens*) is tentative and incomplete (R. P. Ambler, M. Bruschi and J. Le Gall, unpublished observations). The one-letter notation used is that recommended by the IUPAC-IUB Commission on Biochemical Nomenclature[18]. The haem-binding sites are underlined. Residues common to each sequence are shown in capitals. This choice is somewhat subjective, as deletions can be juggled to improve the apparent match.

Oxidation-reduction states

By adding aliquots of sodium dithionite, the reduction at 25° C of the cytochrome c_3 from *Desulfovibrio vulgaris*, prepared as described previously[6], has been studied by following the paramagnetically shifted NMR resonances[7] which lie to very low field (Fig. 1). The number of methyl resonances in this region indicates the number of oxidised haem groups present. By monitoring selected peaks the disappearance and appearance of three different species can be followed readily during a titration (Fig. 2). The titration shows that there must be four haems per molecule which are reduced in two two-electron steps separated in midpoint potential by about 50 mV.

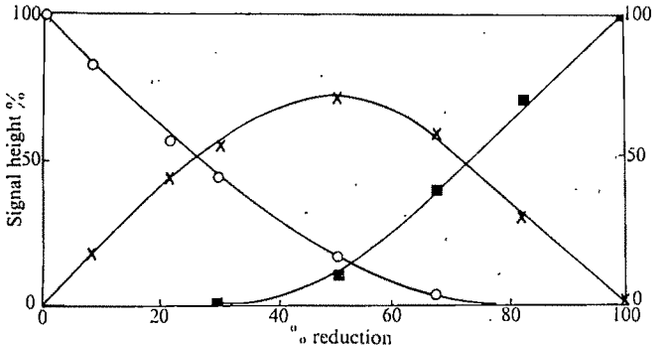

Fig. 1 Appearance and disappearance of NMR lines associated with the three different redox states of cytochrome c_3. O, Concentration of the fully oxidised state which has been followed by measuring the area of several contact shifted methyl resonances at very low field; ×, concentration of the intermediate form, followed by the appearance and disappearance of the new contact shifted methyl resonances on addition of reducing agent, sodium dithionite; ■, the appearance of the diamagnetic form, followed by the appearance of the single proton resonances at very low field attributed to two histidines.

EPR measurements have shown quite independently that the four haems are quite distinct[8]. The NMR reduction-titration (Fig. 2) starts from four distinct and separate paramagnetic haem species, (12-16 low-field methyl resonances, shown more clearly in Fig. 3) has an intermediate of two paramagnetic species (seven or eight low-field methyl resonances) and then gives a fully reduced form of four diamagnetic haem species (no low-field methyl resonances). The reaction is fully reversible and addition of oxygen to the fully reduced species gives an unaltered fully oxidised spectrum. Before discussing the NMR spectra further it is necessary to characterise the spin states of the haems.

The absorption[5,9], the NMR (ref. 10) and the ESR (ref. 8) spectra of cytochrome c_3 from *Desulfovibrio vulgaris* are all characteristic of low-spin Fe(II) and Fe(III) in all oxidation states of the protein. The four cysteine sequences already described as well as the absorption spectra indicate that all the haems are bound through thioether linkages (normal cytochrome *c* links) and thus that one of the iron bound residues of each haem is a histidine of the sequences Cys-*x*-*x*-Cys-His or Cys-*x*-*x*-*x*-*x*-Cys-His. Now as each iron of each haem is low spin it is required to be bound to one other strong ligand which therefore cannot be water or carboxylate, but could be methionine, lysine or histidine. From the *g* values of the EPR spectra of the fully oxidised and half oxidised protein[8], the other ligands are probably nitrogen ligands, that is, either histidine or lysine. The NMR spectrum of the oxidised protein also rules out methionine as a haem ligands, that is either histidine or lysine. The NMR spectrum resonance around +20 p.p.m. (as found in cytochrome *c*)[7] and the absorption spectrum confirms this as there is no 695 nm band typical of methionine binding[9]. McDonald and Phillips[10] have pointed out that the NMR spectrum also excludes lysine as a haem ligand as there are no strongly upfield shifted CH_2 groups. A search of the histidine region of the NMR spectrum revealed only one histidine in its conventional position in all three oxidation states. The four remaining histidines are therefore iron ligands, and in what follows it will be assumed that the four haems are bound to eight of the nine histidines of the *vulgaris* sequence. The sequences of the five proteins in Table 1 strongly confirm this conclusion.

Details of NMR spectra

Using resolution enhancement techniques[11] (compare Fig. 3) the NMR resonance positions of at least one hundred resonances can be followed in each of the three oxidation states. In the fully oxidised state the temperature dependences of the resonances have been studied from 25° C to 55° C. This allows those resonances which are affected by the paramagnetic haem groups (temperature dependent) to be separated from those which are in their normal diamagnetic positions or are shifted from these positions by ring current effects (both temperature independent)[7]. The ring current shifts can then be related to known shifts observed in model compounds using the usual geometric relationships (Fig. 4). The paramagnetic shifted resonances can have been affected either by contact and pseudo-contact shift (this is the case for all groups linked by bonds to the haem iron) or by pseudo-contact shift alone (this is the case for all protein resonances except the groups bound directly to the iron).

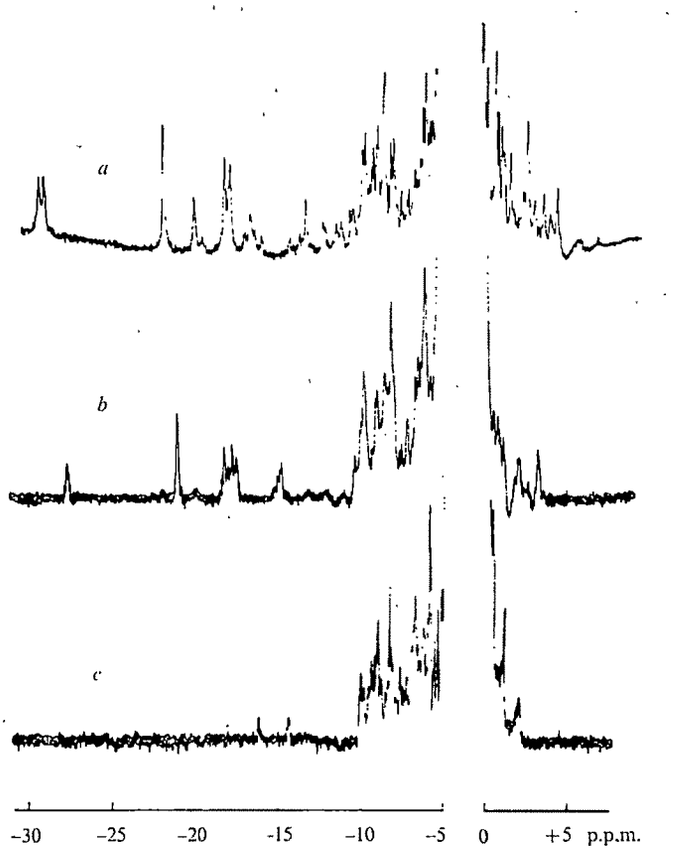

Fig. 2 NMR spectra (measured at 270 MHz) of *D. vulgaris* cytochrome c_3 in the various oxidation-reduction states observed during reduction with sodium dithionite. *a*, fully-oxidised species; *b*, half-reduced species; *c*, fully-reduced species. (Note the vertical scale in *b* and *c* is twice that in *a*.) The titration was carried out with 5 mM protein at 25° C. Dioxan was used as an internal standard but all peaks are referred to TSS.

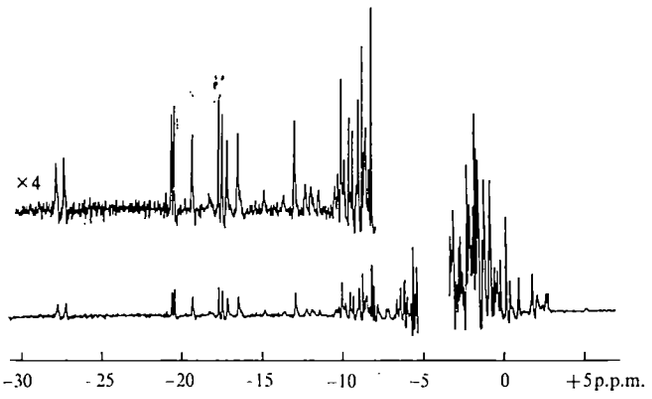

Fig. 3 Resolution enhanced spectrum of oxidised cytochrome c_3 at 50° C.

The pseudo-contact shifts contain much geometric information, which can be used in studies of structure[4,10,12,13]. The greatest problem in using all the shift data, which undoubtedly permit a complete structure determination for this protein, is that of the assigment of the resonances to individual groups. Although we are not yet in a position to carry out such a detailed analysis we can give a qualitative interpretation of our data. We treat each of the three oxidation states in turn.

In the spectrum of fully oxidised cytochrome c_3 there are resonances from +15 to −30 p.p.m. as in cytochrome *c*, but the resonances are spread over the spectrum in a very different way from those in the cytochrome *c* spectrum[7] despite the similarity in EPR *g* values[8]. The most obvious features are shown in Figs 2 and 3. Apart from the fact that there are the expected number of downfield, contact-shifted, haem-ring methyl group resonances (12 to 16 can be seen), there are very many other resonances with large shifts to both high- and low-field. Taking the high-field region first, resonances in this region which show a temperature-dependent shift must either lie in the neighbourhood of and outside the pseudo-contact 'cone' of the haem iron atoms (Fig. 4) or they must experience an appreciable contact shift. From models and studies on other haem proteins, three types of group on the porphyrin are known to give temperature dependent peaks shifted to high field[7]. They are the single proton haem methenes, some of the protons of the propionic acid side chains and at least one of the two methyl groups per haem in the groupings CH_3CH(haem).S-protein, that is the methyl groups of the thioether links. As each of the four iron atoms is bound to two histidines, no other paramagnetically shifted methyl resonances of iron ligands are expected beyond +1.0 p.p.m. Furthermore, in the spectra of all the haem proteins so far examined, no paramagnetically shifted methyl group resonances of non-haem linked residues have been seen at fields higher than +1 p.p.m. In cytochrome *c*, excluding the resonance of the methionine methyl group which is known to be absent in the cytochrome c_3 proteins, the most strongly high-field shifted methyl resonances (due to a thioether methyl group) is seen at +2.2 p.p.m. (ref. 12). By contrast, cytochrome c_3 has some six methyl resonances in the region from +2 to +5 p.p.m. This large number of methyl groups shifted to high field leads immediately to the suggestion that some of the haems are placed end to end producing a region between them of large upfield pseudo-contact shift (see Figs 4, 5). In this region of the spectrum there are also a number of unidentified resonances of one or two protons intensity. Two single-proton peaks are very strongly upfield shifted (+15 p.p.m.) and probably arise from two methene protons.

In the low-field region, apart from the 12–16 contact shifted haem methyl group resonances, there are at least 10 resonances of one proton strength beyond −10 p.p.m. It is likely that these resonances are some of the C_2 and $C_4 \geqslant CH$ groups of histidines which should be strongly downfield shifted by a pseudo-contact mechanism as they are inside the cone (Fig. 4).

The spectrum around −7 p.p.m. where the aromatic protons are generally observed is quite different from that expected, indicating that all or at least most of the five aromatic rings have their resonances displaced by pseudo-contact interactions. Similarly the methyl group resonances, which in a protein normally have strong maxima in the region of −1 to −3 p.p.m. are spread grossly over the whole range from +5 to −5 p.p.m. This is hardly surprising as each of the four haems will interact with some different part of the protein.

The region of the spectrum from −8 to −10 p.p.m. shows only one histidine resonance in roughly the correct position for a possible not bound to iron (see also ref. 10) but it also contains a large number of single proton peaks. We return to these resonances later for they must be very close to the haem group, as is shown by their broadening in intermediate states of oxidation-reduction. It is in this region of the spectrum that >NH resonances are normally observed.

The resonance peaks of the half-oxidised species are readily separated from the fully reduced and fully oxidised

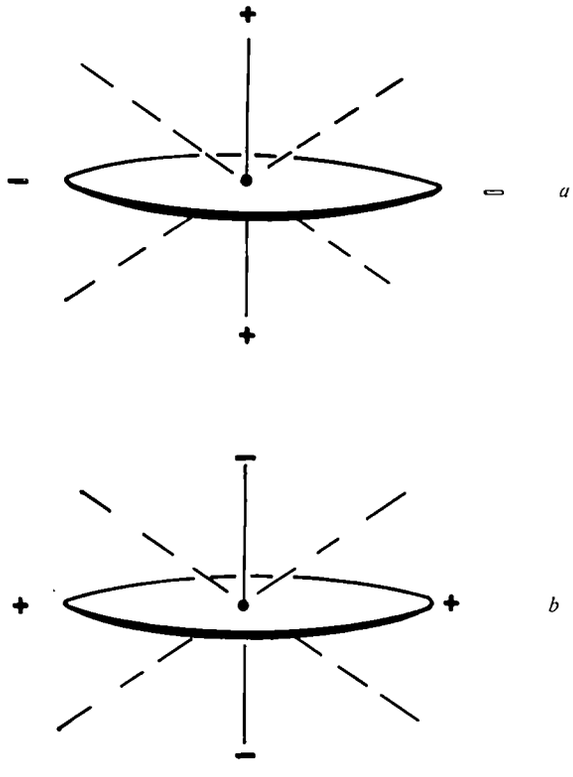

Fig. 4 Schematic representation of the regions of space (cones) which give rise to shifts of NMR resonances. *a*, The case for a ring-current shift which has axial symmetry. Protons lying within the cone experience an upfield shift (+). *b*, Case for axial pseudo-contact shift with the signs appropriate for low spin Fe(III), a proton within the cone experiencing a downfield pseudo-contact shift. As the pseudo-contact term exceeds the ring-current shift by a factor of three, shifts in Fe(III) porphyrin complexes are in the opposed sense to those in diamagnetic Fe(II) porphyrin complexes. In a protein the field around Fe(II) is rhombic, though largely dominated by an axial term, so that care must be taken in the detailed interpretation of pseudo-contact shifts. The cones are derived from a consideration of the angle dependence of shift ($3\cos^2\theta-1$), where θ is the angle between r_i (the vector between the haem iron and the observed proton) and the g_n–axis).

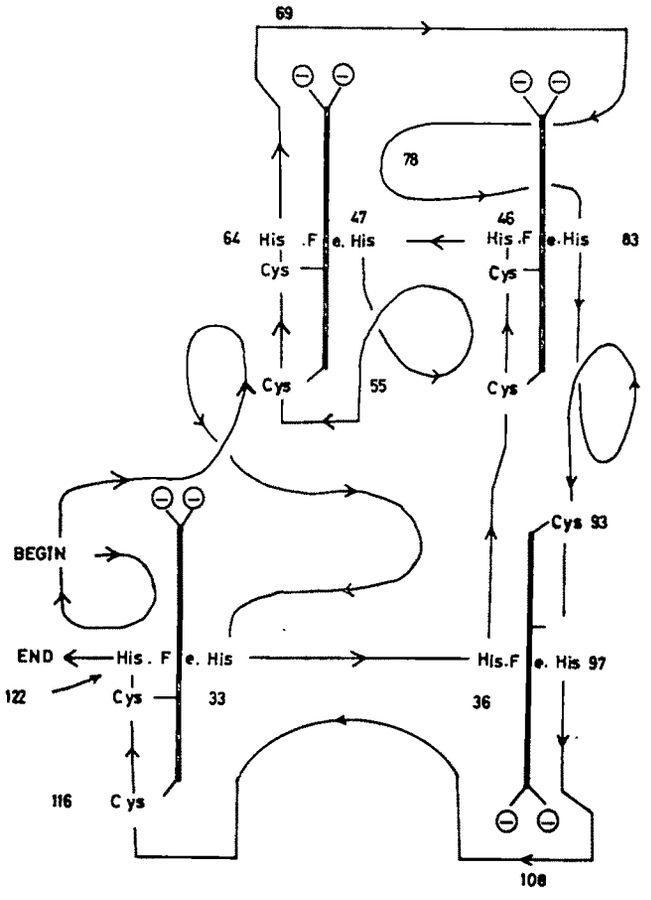

Fig. 5 Proposed outline structure of cytochrome c_3 from *Desulfovibrio vulgaris*.

species (Fig. 2). At very low field, beyond the normal aromatic proton region there are now some six to eight contact-shifted methyl resonances indicating that two haems remain oxidised. There are however only two methyl resonances at very high field, that is above +1.0 p.p.m. although there are also some broad and unidentified one and two proton peaks shifted into this region of the spectrum of oxidised cytochrome *c*, two paramagnetic haem groups replacing the one in cytochrome *c*, showing that the cooperativity required to explain the shifts in the fully oxidised species has disappeared. If two haems in the different oxidation states Fe(II), diamagnetic, and Fe(III), paramagnetic, are packed end to end then the shifts due to one are opposed to the shifts of the other (Fig. 4). The shifts are now anti-cooperative. We emphasise that the downfield contact-shifted methyl resonances move upfield going from fully oxidised to half reduced.

The aromatic protons of the half-oxidised spectrum are again not recognisable in their usual positions but the aliphatic region is more closely that of a conventional haem protein. A single histidine resonance lies in the expected part of the spectrum. The region from −8 to −10 p.p.m. has no structure but as in the oxidised species a rough estimate of the number of >NH protons which do not exchange in D_2O is five to ten.

The fully reduced spectrum has several unusual features. In the upfield region there are more than ten single resonances close to or above 0 p.p.m. We assign many of these single resonances to ring-current shifted protons of histidine bound to iron. They are shifted upfield by the ring current of the haem (Fig. 4). It is known that the α-protons of pyridine bound to a diamagnetic haem are shifted into this region[14]. There is only one possible histidine proton at −8 p.p.m. and thus as in the oxidised and intermediate forms we can state that eight of the nine histidines are bound to the haem. There are no methyl resonances in this upfield region. This shows yet again that unlike cytochrome *c* there are no methionines bound to the central iron. Furthermore, no methyl groups sit centrally inside the cone of the haem rings and close to the haem.

The methyl region, around −2 p.p.m. is now rather similar to that of other proteins. (McDonald and Phillips[10] point out that in fact the methyl region is displaced to low field to some extent.) In the region between −6 and −10 p.p.m. there is a large number of sharp single proton resonances. It is hard to assess the number accurately but it exceeds 10. These are undoubtedly some of the ring methene bridge ⩾CH groups. They are downfield shifted by the ring current (Fig. 4). Again resonances from aromatic protons cannot be recognised in the usual positions. This is expected of course if the aromatic groups are close to the haem so that their resonances experience ring-current shifts. In this region, there is also a number of protons, say five to ten, assigned to nonexchanging >NH from peptide bonds. This region of the spectrum (in D_2O) is not altered after a cycle of oxidation and reduction or after cycling from 25° C to 55° C and holding at the high temperature for some hours, or even after several weeks at 0° C. Some of the >NH protons are very resistant to exchange.

This brings us to the most remarkable feature of the reduced spectrum. At very low field, −14.5 and −16.3 p.p.m., there are two single proton resonances. As this is a diamagnetic system such resonances must originate from >NH groups. It is not possible to conceive of a ring-current shift of minimally 8 p.p.m. downfield of the most downfield ⩾CH resonance. It is known that even the effect on ortho protons of haem-bound pyridine is only about 8 p.p.m. upfield[14], and the chemical shift of imidazole protons of iron-haem ligands is about 0 p.p.m. As the maximum upfield shift is twice the maximum downfield shift, from the angle dependence of shift, $(3\cos^2\theta - 1)$, (Fig. 4), we can eliminate the possibility of downfield shifts of greater than 5 p.p.m. We therefore assign the two resonances to >NH groups of histidine which are known to occur at such a low field in H_2O (ref. 15). Usually such resonances exchange rapidly in D_2O. These two histidines must be in a region of the protein very well protected from water. Since their resonances disappear from this part of the spectrum on oxidation. (Figs 1 and 2), they must be bound to iron.

Introduction of very small amounts of either oxidising or reducing agents to the fully reduced or fully oxidised systems respectively causes a profound change in the line widths of some resonances. In fact all the sharp resonances due to haem protons, for example methene ⩾CH, broadened on altering the redox state of either the fully reduced or fully oxidised protein by less than 10%. These resonances include those assigned to the bound histidines as well as the protons of the haem itself. All the haems seem to be affected. Further oxidation and reduction towards the intermediate form broadens all the resonances with the result that the half-oxidised state gives a relatively poor spectrum in which it is hard to find such resonances as those of the methene bridge protons or those of the histidines. But during oxidation or reduction, well separated resonances of each of the three species titrate without shifting showing that equilibrium between oxidised and reduced species is not fast (on the NMR time scale) for otherwise intermediate resonance positions would be seen.

The broadening of resonances of haem proteins must arise however from relatively fast chemical exchange as the electron relaxation rate of low-spin haem is known to be fast. There are two electron exchange rates to consider: (1) internal exchange between haems of the same protein molecule and (2) exchange between different protein

molecules. A full study of the reaction rates with temperature and concentration will give much knowledge of the electron transfer process in proteins but it is clear that the electron exchange is of intermediate rate rather than very fast or very slow.

Structural features

The sequence and the NMR data on *Desulfovibrio vulgaris* cytochrome c_3 can now be put together. The short lengths of sequence between haem-bound histidines at residues 46–47 and 33–36 force the planes of the haems to be roughly parallel pairs. Each haem is bound to two histidines and to two thioether links. At least some of the haems must also be close together and stacked end to end as the large cooperative upfield shifts of the methyls of the thioether bridges in the fully oxidised state indicates. The anticooperativity of ring-current and pseudo-contact interactions of the haems provided by the arrangement in Fig. 5 also fits observations from the data on the half-oxidised and fully-reduced states. The histidine 80 which is not haem-bound and is found in a normal position in the NMR spectrum is only found in *Desulfovibrio vulgaris*[10]. The aromatic groups must now be placed reasonably close to the haem centres for they do not appear as normal aromatic resonances in the NMR spectra of any of the three forms we have studied. It is also known that in haem proteins it is usual for the two carboxylate residues of the haem to be neutralised by basic groups in their vicinity. In Fig. 5 we have placed invariant basic residues close to the carboxylate groups. McDonald and Phillips[10] point out that the NMR spectra indicate that the lysines are on the outside of the molecule.

The model agrees with the observation on *Chloropseudomonas ethylica* that many (26) amino acids from 55 to 90 and histidine 47 which binds to the haem in the top left hand corner of Fig. 5 are missing. In the three-haem cytochromes this haem must be absent. We have built a working three-dimensional model of the structure to prove that it fills space in a satisfactory way. The distance between haems is about 10 Å, in agreement with assessments of this distance based on one interpretation of the optical spectroscopy[9,16].

Further details of the structure can be unravelled by a thorough assignment of the resonances, and a calculation of the resonance shifts together with model building. Further NMR probes can be introduced as becomes necessary.

The most interesting feature of the protein is that despite the fact that the haems are close together (about 10 Å apart) and are separated by only a single polypeptide chain (Fig. 5) there is relatively slow electron exchange between them. Thus such a protein is not a simple electron conductor but is more likely a storage unit, a capacitor, for electrons. It cannot be the case that normal amino acid residues can give rise to a path for rapid electron exchange. In a model experiment we have shown that collision between low-spin Fe(II) and Fe(III) haems provides fast exchange[17]. Thus the haems in cytochrome c_3 (as in other cytochromes) are not able to come into close contact through intermolecular collisions. The possibility remains that these proteins are devices for multielectron reactions in which electrons are released one at a time but in rapid succession.

C. C. McDonald and W. D. Phillips have measured[10] independently the NMR spectrum of cytochrome c_3. Their data and deductions are very similar to ours. We wish to acknowledges their friendly cooperation. R.J.P.W. is a member of the Oxford enzyme group. C.F.G. acknowledges the receipt of a NATO grant. We thank Dr R. P. Ambler for permission to reproduce the sequences given in Table 1.

Shell flashes in planetary nuclei

THE central stars of planetary nebulae may be the ancestors of some of the white dwarfs[1-3], and the magnetic white dwarfs in particular may have originated in this way[4,5]. There seem to be no mechanisms in the white dwarfs themselves capable of producing fields of the strengths observed, and the magnetic field must therefore be a fossil remnant of an earlier phase of evolution. The hypothesis that a high internal field is exposed by the ejection of the nebular shell has an appealing simplicity.

A satisfactory explanation for the postulated high internal fields in the planetary nuclei has not yet been suggested. Conservation of magnetic flux from the main sequence phase of evolution is adequate only if the main sequence progenitors of the planetaries have average field intensities $B \sim 10^3$

gauss. Such fields do exist in the magnetic A stars, but they seem to be too massive to be the ancestors of the planetaries.

We point out here that a natural mechanism for the production of strong magnetic fields may in fact be present in at least some planetary nuclei. A prominent feature of the evolution of such stars is the occurrence of one or more thermal runaways, 'flashes', in an unstable shell source which produces nuclear energy[6]. Near the peak of a flash a transient convection zone is invariably developed[7-11], and if the star has even a modest amount of differential rotation, the generation of magnetic field in a stellar dynamo can occur. This hypothesis was suggested to us by the recent paper of Ruderman and Sutherland[12], in which it is argued that the transient convection accompanying the explosive burning of carbon in carbon-detonation supernovae, will tangle up any initial 'seed' magnetic field and perhaps cause amplification to the equipartition field strength.

In order to investigate the plausibility of dynamo field generation in the planetaries, it is necessary to have estimates of the rate of differential rotation and of the properties of the transient convection zones in these stars. We are unaware of any determinations of the rotation of planetary nuclei. One of the magnetic white dwarfs is, however, known to rotate with a period, P, of 1.33 d (ref. 13). If this star has indeed evolved from a planetary nucleus, conservation of angular momentum implies a period $P \sim 10^2$ d for the ancestor of the white dwarf. This value seems conservative, and we therefore adopt it for our calculations.

As even less is known about the differential rotation of planetary nuclei, we adopt $\Delta P/P \sim 0.1$, the value appropriate to the sun, where ΔP is the magnitude of the difference in rotation period between the pole and the equator.

Because the precise details of the evolutionary history of the planetaries are uncertain, the exact structure of such stars immediately before the expulsion of the nebular shell is unknown[6]. As a result, a considerable variety of models have been suggested for these objects. Thus, Rose and Smith[7] and Paczynski[8] consider instabilities in the He-shell of double-shell-source models; Wood and Faulkner[9] consider the shell-flash in pure helium stars; Joss *et al.*[10] investigate models in which either He- or C-shell flashes can occur; and Kutter and Savedoff[11] consider shell flashes in pure carbon stars. Unfortunately, except in the latter paper, only very schematic information is given about the structure of the convection zones, and we therefore rely on rather crude estimates for the convective velocities.

The following results are typical of these models. For models that exhibit a He-shell flash[7-10]: the stellar mass is $M \sim 0.8 M_\odot$; the mass of the helium envelope—which is almost entirely convective at the peak of the flash—is $\sim 2 \times 10^{-3} M_\odot$ (the convection zone may, however, cover a substantial fraction ($\sim 1/2$) of the stellar radius; the density at the He-burning shell ρ is $\sim 2 \times 10^3$ g cm^{-3}; the convective velocity v is $\sim 3 \times 10^5$ cm s^{-1}; and the duration of the transient convection is $\sim$10–100 yr. For models that exhibit a C-shell flash[10,11]: the stellar mass is $\sim 1.1 M_\odot$; convection covers $\sim 1/3$ of the stellar mass; the density at the C-burning shell ρ is $\sim 10^5$ g cm^{-3}, the convective velocity v is $\sim 10^5$ cm s^{-1}, and the duration of the transient convection is $\sim 2 \times 10^2$ yr. In either case the stellar radii R are $\sim 0.1 R_\odot$ (as they must before planetary nuclei) and the equipartition magnetic field strengths B_{eq}, are $\sim (8\pi \cdot (1/2)\, \rho v^2)^{\frac{1}{2}} \sim 10^7$–$10^8$ gauss. This is more than adequate to account for the magnetic fields of $\sim 10^7$ gauss detected in the magnetic white dwarfs (which have radii of about $\sim 10^{-2} R_\odot$), provided that the transient convection lasts long enough for the dynamo to generate such fields.

In the conventional picture of a dynamo[14], an initial poloidal 'seed' field of intensity B_0 is distorted by the differential rotation to produce a toroidal field component. This is a continuing process, with the toroidal field doubling in a time $\tau \sim P^2/\Delta P$. At the same time a new poloidal field is generated by the action of the cyclonic convection, which lifts and twists the toroidal field lines[14]. Growth of the field is ultimately halted when the magnetic intensity approaches the equipartition field strength, B_{eq}; not only is the convection then too weak to deform the field lines, but also the stronger field suppresses the convective motions.

That this schematic picture is qualitatively correct can readily be seen by applying it to the Sun. In the solar convection zone, $B_{eq} \sim 4 \times 10^3$ gauss, which is the order of magnitude of the fields seen in sunspots, where magnetic field lines from the interior protrude through the solar photosphere. Furthermore, the doubling time is $\tau \sim 1$ yr, and the time required for an initial 'seed' field of intensity $B_0 \sim 1$ gauss (the general solar field) to reach this limiting intensity is $t \sim \tau \log_{10}(B_{eq}/B_0)/\log_{10} 2 \sim 10$ yr, which is almost exactly half the sunspot cycle.

For the planetary nuclei, our previous estimates of the differential rotation indicate a doubling time $\tau \sim 3$ yr. If the initial 'seed' field is again taken to be $B_0 \sim 1$ gauss (it would be $\sim 10^2$ gauss if flux conservation from the main sequence were assumed), the time required for the field to reach its equipartition strength of $\sim 10^7$–10^8 gauss is $t \sim \tau \log_{10}(B_{eq}/B_0/\log_{10} 2 \sim$ 70–80 yr. This is comparable with the duration of the transient convection zone, and it therefore seems entirely possible that fields of the intensity ($\sim 10^5$ gauss) required in order to explain the magnetic white dwarfs can be generated in at least some planetaries.

It is tempting to suggest that the production of a magnetic field necessarily accompanies the ejection of a planetary nebula or even, perhaps, that nebular ejection is caused by the production of strong magnetic fields. This is certainly premature at present, although if the latter conjecture were true, all planetary nuclei should have strong magnetic fields, and it should be possible to verify this by observation.

If dynamo generation of strong magnetic fields actually occurs during shell flashes in planetary nuclei, as we have suggested, a prime candidate for the observational test of this hypothesis would seem to be the remarkable star FG Sge. This star is known to have ejected a planetary nebula $\sim$6,000 yr ago, and it seems to be undergoing an active shell flash at the present (refs 8, 15, and G. E. Langer, *et al.*, unpublished information). Most remarkable, however, is the recent discovery (G. E. Langer, *et al.*, unpublished information) that the surface layers are currently being enriched in s-process nuclei, which are thought to be produced in the He-shell flash. Along with these nuclei strong magnetic fields would also be expected to be transported to the surface if our hypothesis is correct. Measurements of the magnetic field of this star thus seem to present a crucial test of this idea.

Gravity-induced electric polarisation near the Schwarzschild limit

IT has long been recognised that besides carrying the fundamental unit of charge an electron is also endowed with inertia. Only recently has attention been paid to the possibility that phenomena may exist which depend on the gravitational mass[1]. Here we point out that strong gravitational fields, such as those encountered in collapsed stellar objects, may produce observable electromagnetic effects arising directly from the gravitational mass of electric charges.

Some sixty years ago Tolman and Stewart[2] described an experiment in which the inertia of electrons is revealed. This involved a conductor, such as a circular horizontal wire, which oscillates about a vertical through its centre. Because of their inertia the free electrons will move relative to the crystal structure of the wire and so an oscillating current will be generated. To a first approximation, if **a** is the acceleration of the wire at any instant, then as far as the free electrons are concerned an effective electric field **E** given by

$$\mathbf{E} = \left(\frac{m}{e}\right)\mathbf{a} \qquad (1)$$

is present in the reference frame of the wire (m and e are the electronic mass and charge, respectively). In principle a method for obtaining the specific charge e/m was made available.

From the point of view of relativity theory, we may regard the acceleration of the wire as equivalent to the action of a gravitational field (of oscillatory character in the above case), in accordance with Einstein's principle of equivalence. In fact whenever a conductor is held in a gravitational field **g** we may expect an effective electric field

$$\mathbf{E} = -\left(\frac{m}{e}\right)\mathbf{g} \qquad (2)$$

to be manifested to the free electrons. In this case m is the electron's gravitational mass, indistinguishable from the inertial mass in the light of the equivalence principle.

If this is the effect of gravitation on free electrons (admittedly a very small one in the gravitational field of the Earth) then a corresponding phenomenon must influence bound charges in a dielectric. We may think of this as a gravitational polarisation

$$\mathbf{P} = \chi\mathbf{E} = -\chi\left(\frac{m}{e}\right)\mathbf{g} \qquad (3)$$

where χ is the gravitational susceptibility of the dielectric. If indeed **P** exists then, as in ordinary electric polarisation, an equivalent volume distribution of charge $-$ div. **P** and surface distribution **P.n** would result in accordance with conventional analysis.

For the gravitational field of the Earth such a polarisation no doubt produces extremely small consequences. But in a collapsed star lying near to its Schwarzschild limit the local value of g may be large enough to produce observable effects, especially in conjunction with a rapid rotation of the star[3]. Thus if we apply the usual Schwarzschild metric to a condensed object then the local value of the gravitational intensity on the surface $R = R_S$ is given by

$$g = (GM / R_S^2)\,(1 - [2GM/(c^2 R_S)])^{-1} \qquad (4)$$

M being the total mass and G the Newtonian gravitational constant. Here g is the proper acceleration (invariant) of a freely falling test particle relative to the fixed surface, and is equal to the magnitude of the first curvature vector of the world line of an atom fixed under stress at $R = R_S$. Equivalently g is the acceleration (in the opposite direction) of the fixed atom relative to a freely falling geodesic frame instantaneously at rest at $R = R_S$. Clearly if $R_S = R^*$, where $R^* = 2GM/c^2$ (the Schwarzschild gravitational radius) g may become extremely large, with corresponding intensification of the effects we have described on free and bound electric charges. Even in a neutron star (the limiting consequence of these effects) there will be such charges near the surface.

We now consider in particular what happens to a 'standard clock' S located in such intense gravitational fields. If the standard clock is an atomic emission line then we cannot expect this to be at the standard laboratory frequency in such circumstances. There must necessarily be an effect related to the electric Stark phenomenon. For example although the usual redshift formula will apply to the emitted radiation as received by a remote observer O, it is not sufficiently realised that this formula gives only the ratio ν_S / ν_0 for the frequencies emitted and observed in terms of the change in the gravitational field between S and O. It tells us nothing about the emitted frequency absolutely. The emitted frequency will in fact be standard only for an atom in free fall, or when the gravitational field is negligible. It is usually assumed in the case of the Sun, for example, that these conditions prevail. But clearly the assumption is invalid when we consider an atom fixed on the surface of a highly condensed object.

Meteorological features affecting large aperture synthesis radio telescopes

VARIATIONS of atmospheric radio refractive index can cause phase differences between signals received at spaced aerials and limit the resolution of large radio telescopes using the aperture synthesis technique[1]. Hinder[2] found that anomalous phase differences recorded at the One-Mile telescope at Cambridge[3] were caused by thermal updraughts and fair weather cumulus; the mean size of the irregularities was 700 m. Earlier calculations[4] had shown that the gradients of refractive index across fronts were likely to be important but it was believed that corrections using ground-based measurements of pressure, temperature, and humidity could be applied to reduce errors from such large scale ($\approx$ 500 km) weather systems[5].

The first few months of observing with the 5-km telescope at the Mullard Radio Astronomy Observatory, University of Cambridge, showed that there were frequent significant effects from intermediate systems, with scales of 10 to 100 km or more. An investigation was undertaken to relate these periods of anomalous phase changes—'events'—to meteorological phenomena and the results are summarised here.

Telescope operational periods (excluding those spent observing complex emitting regions) event times to within 1 h and event intensities, for part of May, June to September, and

(a) Total duration of events in tenths of an hour. (b) Period of operation of telescope in tenths of an hour. (c) % of operational time occupied by events.
* May data commenced on May 21.

December 1972 were considered. The intensity of an event is a normalised measure of the rate of increase in phase shift with aerial separation with first order geometrical differences removed. The observational programme was independent of weather conditions.

Table 1 gives the distribution of events by month and time of day. The data for December show that in winter, when the absolute water content of the atmosphere is at a minimum, events are likely to pose less of a problem, so the analysis was confined to the period May to September.

A classification of vertical variations of temperature, based on radiosonde reports for Hemsby (52° 41′ N, 01° 41′ E) and Crawley (51° 05′ N, 0° 13′ W), showed no relationship with occurrence of events; however, some events appeared to be associated with sharp vertical gradients of humidity marking the lower boundary of very dry mid-tropospheric layers. Such layers are associated with fronts[6] and may persist long after the front becomes inactive; such an association implies a sloping interface and hence a much larger horizontal gradient of radio refractive index than might be expected with more extensive dry layers in anticyclones.

Table 2 Precipitation at Cardington during operational periods at Cambridge (May to September only)

	Moderate or heavy rain	Thunder	Showers	Slight rain	Dry	Total
Event	3.9	1.0	18.6	12.2	164.4	200.1
No event	6.1	2.0	31.9	48.9	683.0	771.9
% of time occupied by events	39.0	33.3	36.8	20.0	19.4	20.6

All values are given in hours and tenths.

Considerations of 12-h changes in air mass characteristics at Hemsby and Crawley, and pressure variations recorded by the microbarogram at Kew Observatory, were inconclusive; in both cases only the few large changes showed any possible association with events. No additional relationships were found from a study of more detailed vertical soundings in the lowest 1,200 m, carried out four times daily at Cardington (52° 06′ N 00° 25′ W).

When hourly weather reports from Cardington were scrutinised, some events were found to coincide with the onset or cessation of rain. Table 2 gives the total times in hours and tenths when various precipitation types and intensities occurred in operational periods with and without events. If slight rain is disregarded, the relationship between events and other precipitation types is significant at the 0.1% level. No event in September coincided with precipitation (at Cardington); indeed a 12 h operational period from 1745 GMT on 8 September marked by continuous, sometimes heavy, rain throughout was free of events. Recent investigations into the structure of frontal systems[7,8] have established the existence of rain bands of approximate scale 100 × 30 km, within which are 'clusters' of order 20 × 30 km marked by higher rainfall rates; these could explain the relationship between moderate and heavy rainfall and events. The prolonged rain of September 8 and 9, mentioned above, did not seem to conform to this model. On that occasion rapid and intense cyclonic development occurred off South-west England, the resulting depression passing near Cambridge. In the early stages of a development of such intensity, the precipitation structure would not be expected to have consisted of organised cluster bands. Events were also noted during periods of convective activity. This is not surprising in view of the large humidity contrast between the upward rising convective columns and the neighbouring drier environment, and typical variations[9] in the depth of the convective boundary layer on distance scales of tens of km.

This investigation was limited by the lack of fine scale meteorological data, particularly upper air observations, from the vicinity of the telescope itself; a detailed synoptic study would require surface and upper air observations at the site. But it has indicated three systems which may have caused many of the phase differences observed: rain 'clusters'—usually associated with fronts, areas of showery activity and occasional very dry mid-tropospheric layers. These systems are all associated with humidity or liquid water content variations in the vertical and the horizontal, which are not limited to the lowest layers of the atmosphere. Therefore the likely frequencies of such systems must be taken into account when considering sites for new radio telescopes.

Neutral oxygen in comets

MEASUREMENTS of the strength of permitted spectral lines from neutral oxygen in comets should provide both a better understanding of gas dynamics in comets and an assessment of whether the production ratio of oxygen to hydrogen in comet atmospheres is close to a half. If this ratio is confirmed, it would provide strong support for the growing evidence[1] that the 'parent' molecules which make up the solid comet nucleus are dominantly H_2O.

A better understanding of the role of H_2O in comets can be obtained from the study of both atomic oxygen and hydrogen. Most observations of atomic oxygen in comets seem to be of the forbidden lines at 6,300 Å and 6,363 Å. These lines presumably occur only in cases in which an oxygen atom was left in the $^1D_2$ level at the time of dissociation, and they are thus related to the production rate of atomic oxygen rather than to the oxygen density (ref. 2). Measurement of permitted oxygen lines which result from photoexcitation by solar photons would provide a direct probe of neutral oxygen density.

Photoexcitation of neutral oxygen from the $2p^4\ ^3P_2$ ground state to the $3s\ ^3S_1^0$ level gives rise to three resonance-fluorescence lines at 1,302 Å, 1,305 Å and 1,306Å. These lines have been observed in the upper atmospheres of both Venus and Mars[3,4] and in Comet Kohoutek[5]. The fact that the same OI lines appear in emission in the solar chromosphere can considerably enhance the fluorescence. In a cometary atmosphere, however, the neutral oxygen may not be excited by these lines if the radial velocity of the comet with respect to the Sun is large enough to Doppler shift the wavelength of the exciting lines. In this case the excitation would be expected to be by the solar continuum, which is of a much lower intensity than the chromospheric OI lines. There is, however, another method of exciting OI in a comet. This is possible because of the almost exact coincidence of the oxygen lines at 1,025.77 Å and the Lyman-β hydrogen line at 1,025.72 Å, which appears in emission in the solar chromosphere (see also ref. 6). Lyman-β has a width of approximately 0.4 Å in the Sun, and therefore the radial velocity of the comet with respect to the sun will not be enough to prevent the occurrence of fluorescence.

The neutral oxygen atoms in the $3p^4\ ^3P_2$ ground state are excited to the $3d\ ^3D^0_{3,2,1}$ states by Lyman-β photons. The excited OI atoms can return to the ground state either by direct transitions, or through transitions to the $3p\ ^3P$ and $3s\ ^3S^0$ states, which will give rise to lines at 11,287 Å, 8,446.5 Å and the three lines near 1,304 Å. There is thus the interesting possibility of detecting the presence of neutral atomic oxygen in comets, from allowed transitions in the near infrared spectrum.

The concentration of neutral oxygen in the atmosphere of a comet will depend on the rate of production, the rate of escape from the nuclear region and the rate of removal by ionisation. The rate of production of oxygen can be deduced if it is assumed that the hydrogen cloud around a comet is the result of photodissociation of water vapour, in which case the rate of production of oxygen should be half of the rate of production of hydrogen.

The rate of escape of oxygen from the nuclear region is difficult to estimate accurately, because there is evidence that collisions in the region near the nucleus may be rather frequent[7], resulting in an equipartition of energy between the component particles. In this case the outflow velocity of oxygen atoms into the coma would be a quarter of the hydrogen velocity. For oxygen atoms released by photodissociation of OH at a distance from the nucleus, conservation of momentum imparts a velocity to the oxygen atoms of one sixteenth that of hydrogen.

The ionisation of hydrogen in comets is predominantly a result of charge exchange by protons in the solar wind. This mechanism is about 10 times more important than photoionisation[8]. The lifetime against photoionisation of oxygen by solar photons (found from the cross sections in ref. 9) is very close to that for hydrogen. The cross section to ionise oxygen by charge exchange with solar wind protons is, however, two to three times smaller than the hydrogen cross section[10], so the total lifetime of neutral oxygen atoms is still determined by the lifetime against charge exchange. The smaller charge-exchange cross section of oxygen allows most of the oxygen atoms from a comet 1 AU from the Sun to remain neutral out to at least 10^6 km from the nucleus, in spite of their lower velocities. At a distance of 10^6 km from the nucleus, the oxygen density is about two to five times that of hydrogen, for hydrogen to oxygen velocity ratios of 4 and 16 respectively, assuming that the hydrogen and oxygen atoms both come from H_2O.

From the published transition probabilities[11] for O and H the photon flux of the 8,446.5 Å OI line from a comet can be estimated in terms of the 6,563 Å Hα line, because both are nearly proportional to the Lyman-β flux from the Sun. The calculated photon flux for the 8,446.5 Å OI line is 0.8 to 2.0 of the Hα flux, when the oxygen density is two and five times the hydrogen density respectively. This assumes that the comet is optically thin to the solar Lyman-β photons, but as both the oxygen and hydrogen clouds in the comet are expected to be considerably larger than the radius at which Lyman-β becomes optically thick (about 10^5 km) (ref. 12), it seems justifiable to assume a small optical depth.

The observation of Hα in Comet Kohoutek, using a Fabry–Perot interferometer[13], suggests that it might be possible to observe the OI line at 8,446.5 Å using an instrument with a high enough resolution to discriminate against the continuous background spectrum. Such observations, together with more observations of the far ultraviolet spectra of hydrogen and oxygen, the OH emission at 3080 Å, and the forbidden oxygen lines at 6,300 Å and 6,363 Å, may provide sufficient information on the physical and dynamical processes occurring in comets to allow a critical evaluation of the importance of H_2O in the dirty-ice model.

PAN over the Atlantic and the smell of clean linen

OZONE, at concentrations in excess of 0.1 parts per million (p.p.m.), has been observed in the summertime air over southern England[1]. The most probable source is photochemical reaction among air pollution products. We therefore sought the presence of another characteristic product of urban atmospheric photochemistry[2], peroxy acetyl nitrate (PAN). Preliminary measurements (S. A. Penkett and F. J. Sandalls, personal communication) show that PAN is present in the air over southern England. During episodes of increased ozone and other atmospheric pollution indicators the concentration increased, but as with ozone there was always a background concentration of PAN even in clean air arriving from the Atlantic. The voyage of the German Research Vessel Meteor from Hamburg to Santo Domingo in October 1973 presented an opoprtunity to discover whether or not there is a natural background of PAN.

Analysis was by gas chromatography using an electron capture detector. Air samples were collected at the bows of the ship by drawing 5 ml of air into a glass syringe; the sample was then quickly injected into the gas chromatograph. The apparent concentration of PAN during the voyage is shown in Fig. 1. Concentrations of CCl_3F are also included because increases in the background level of this compound indicate the presence of air from urban industrial regions[3]. The term 'apparent' is used because it was discovered during the voyage that the unexpectedly high concentrations over the Atlantic were not present in the air, as such, but had formed by reaction on the glass surface of the sampling syringe. No PAN could be detected in air collected in polypropylene syringes, but the addition of a twist of glass wool to such syringes before the air was drawn into them restored the concentration to levels similar to those found with glass syringes. One-litre samples of fresh air were also drawn through plugs containing 1 g of glass or cotton wool, and these were found to be strong sources of PAN and of peroxy proprionyl nitrate (PPN). In addition the wools possessed the characteristic bleach-like odour of linen after it has been dried in the open air. The PAN potentials of Fig. 1 are approximate and probably too low. No corections were made for losses by adsorption or for the extent to which the detector was not coulometric.

The potential for formation of PAN was most marked on days of unobstructed sunshine (see Fig. 1). October 13 and 14, when the ship passed through a polluted air mass (which was indicated by the high concentrations of CCl_3F) were exceptions. PAN formation was greatest at approximately 1400 h and was between 3 and 10 times lower at dawn and in the evening. Simultaneous measurements from the ship, of the aerial concentration of atmospheric hydrocarbons, indicated levels of betwen 0.1 and 2 parts per 10^9 (p.p.b.) for the lower unsaturated hydrocarbons (R. A. Rasmussen, personal communication). The sea was apparently the most probable source. The concentration of

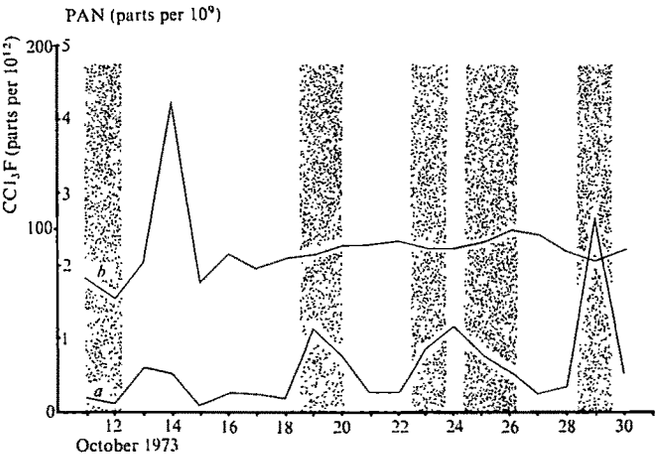

Fig. 1 PAN from the air over the Atlantic. Average daily concentrations of 'apparent' PAN × 10^{-9} (*a*) and $CCl_3F \times 10^{-12}$ (*b*) by volume. Shaded columns indicate days with less than 50% cloud cover.

the other ingredients necessary to form PAN by photochemical reaction were not measured. Ozone is ubiquitous and can be presumed to have been present in at least its background concentration of about 50 p.p.b.

These preliminary observations suggested that PAN and similar compounds can be formed in the clean air of remote maritime regions by heterogeneous reaction if a suitable surface is provided. They raise some interesting and important questions. What are the mid-Atlantic precursors? Is PAN formation in urban photochemical smog also by heterogeneous reaction? If so what is the surface on which it forms? Finally the quantities of PAN observed suggest the presence of a high background concentration of NO_x or of some related molecular species.

We are grateful to the Deutsche Hydrographische Institut and the Captain, Officers and men of the Meteor for the opportunity for one of us (J.E.L.) to voyage with the ship. We thank Shell Research Ltd. and the Natural Environment Research Council for their financial support.

Vertical distribution of heat production in the Basement of the Eastern Alps

A LINEAR relationship between heat flow and heat production within plutonic bodies has been observed by a number of researchers[1,2] and can be written:

$$q = q^* + DA(0) \quad (1)$$

where q is the surface heat flow, $A(0)$ is the surface heat production, and q^* and D are constants within a given geographic province.

Many heat production–depth models satisfy equation (1), but Lachenbruch[2,3] suggests that an exponential model (equation (2)) is needed if equation (1) is to be preserved after differential erosion of the source layer.

Thus, the following equation is initially assumed to be valid for the area under discussion:

$$A(z) = A(0)\exp(-z/D) \quad 0 < z \leqslant z^* \quad (2)$$

Data are therefore presented in the form:

$$\log_e A(z) = \log_e A(0) - z/D$$

$$\text{or } z = -D\log_e A(z) + D\log_e A(0) \quad (3)$$

The distribution of heat production with depth in a granitic terrain is discussed here and the results of this direct measurement approach are compared with those already obtained from heat flow data elsewhere. The granitic rocks (the Zentralgneis) from the Pennine Basement of the Tauern Window in Austria were chosen because of the excellent exposure and because a vertical section of 4 km is available for sampling.

The Zentralgneis is a Variscan polyphase intrusive series of tonalites, granodiorites, and granites, which has undergone deformation, and subsequent amphibolite facies metamorphism during the Tertiary. A representative sample of the lithologies within each unit 1 km thick was obtained whenever possible. Particular care was taken to ensure that each unit was represented by a similar number of samples. Measurement of the amounts of uranium, thorium, and potassium was carried out using standard γ-ray spectrometry techniques and heat production was calculated from these data using the formula published by Birch *et al.*[1].

The depth of each sample (m) was calculated from a map published by Cliff *et al.* (ref. 4, page 234) on which the contours of the projected base of the overlying unit, the Peripheral Schieferhülle, are extrapolated over this area. Errors are difficult to estimate but are thought to be no greater than ±250 m over the whole of the sampled area.

Heat production falls off markedly with increasing depth (Fig. 1); but the scatter of data points is such that it is not possible to distinguish an exponential model from, for example, a linear diminution of heat production with depth. The same problem of a high background noise on the fitted curve also led Lachenbruch and Bunker[5] to an identical conclusion in the only other attempt to verify the exponential model by direct measurement.

In both cases, the difference in scale between the thermal equilibrium, which enables a heat flow value to be representative of large volumes of rock, and the petrological and geochemical equilibria, which are commonly confined to a sample the size of a hand specimen in such terrains appears unbridgable. But heat flow values tend to smooth out the small scale chemical inhomogeneities and, it is therefore possible that such a geophysical approach will add a new large scale dimension to the petrogenetic studies of composite intrusive series.

The second important result is that, although heat production does fall off with depth as predicted by Lachenbruch's interpretation of the heat flow data, it falls off considerably faster in the Zentralgneis than in any other province so far investigated.

Lachenbruch has explained the linear relationship described by equation (1) in terms of a steady state one-dimensional model, assuming the lateral gradients in heat production to be negligible compared with the vertical gradients. Consequently, the vertical section of 4 km in the Zentralgneis has been subdivided into four horizontal units 1 km thick and the

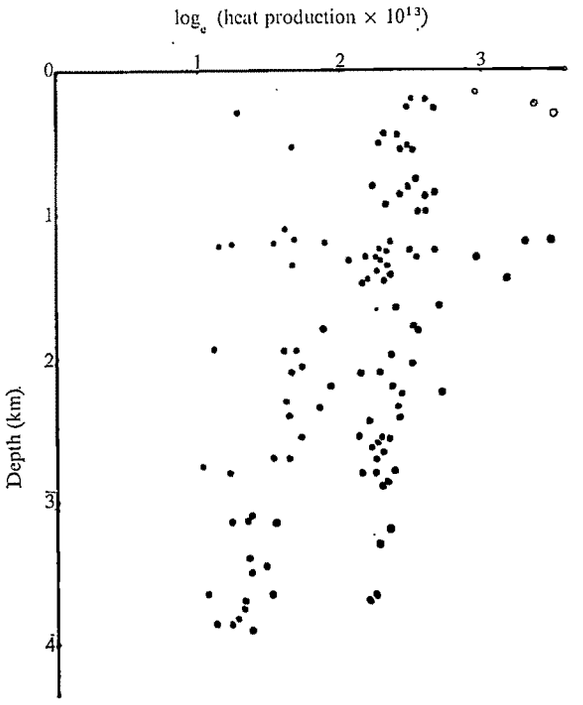

Fig. 1 Distribution of log$_e$ (heat production × 10^{13}) with depth (km) below the top of the basement complex in the Tauern Window. All samples were taken from the metaplutonic rocks of the Zentralgneis.

mean heat production of each unit has been calculated. The results are then presented in the form of equation (3), that is, a straight line graph of log$_e$ (heat production × 10^{13}) against depth (Fig. 2). The slope of the best fit straight line gives $D = 3.5 \pm 1$ km (2σ).

Considering the scatter of the original data, the fit of the mean values of heat production to the best straight line is remarkably good. It is, however, apparent from Fig. 2 that the value of D is to some extent controlled by the surprisingly low value of mean heat production in the fourth unit. This low value is a result of the relative depletion of uranium with respect to thorium in the basal unit, which in turn reflects the fact that it is only at this structural level that tonalite predominates over the other, more fractionated, granitoid lithologies. It is, however, difficult to further evaluate this low value of mean heat production because the rocks exposed in the basal unit crop out in a smaller area than those of the other three units; and it is not known how typical the lithologies in the fourth unit are of this structural level in the Zentralgneis.

Nonetheless, despite these geological ambiguities concerning the value of mean heat production in the basal kilometre, the scatter of the values of log$_e$ (mean heat production × 10^{13}) about the best straight line (Fig. 2) is within the assigned experimental errors. Consequently, the distribution of heat production with depth in the Zentralgneis seems to be consistent with an exponential model (equation (2)) in which $D = 3.5 \pm 1$ km, and $A(0) = 15.7 \times 10^{-13}$ calorie cm^3 s^{-1}.

Other workers have reported results obtained from both heat flow[1,2] and direct measurement techniques[5], which are consistent with $D = 9$–10 km. Roy *et al.*[6], however, suggested that in stable continental areas, D may be approximately 7.5 km. All these values are significantly greater than the value of D reported here.

Although the Zentralgneis has been deformed and metamorphosed to amphibolite facies, recent geochemical work (C. J. Hawkesworth, unpublished) and the preservation of premetamorphic Rb/Sr whole rock ages[7], suggests that on a large scale a primary igneous distribution of elements is being observed. Consequently, the low value of D cannot be explained by late upward concentration of the radioactive elements during metamorphism.

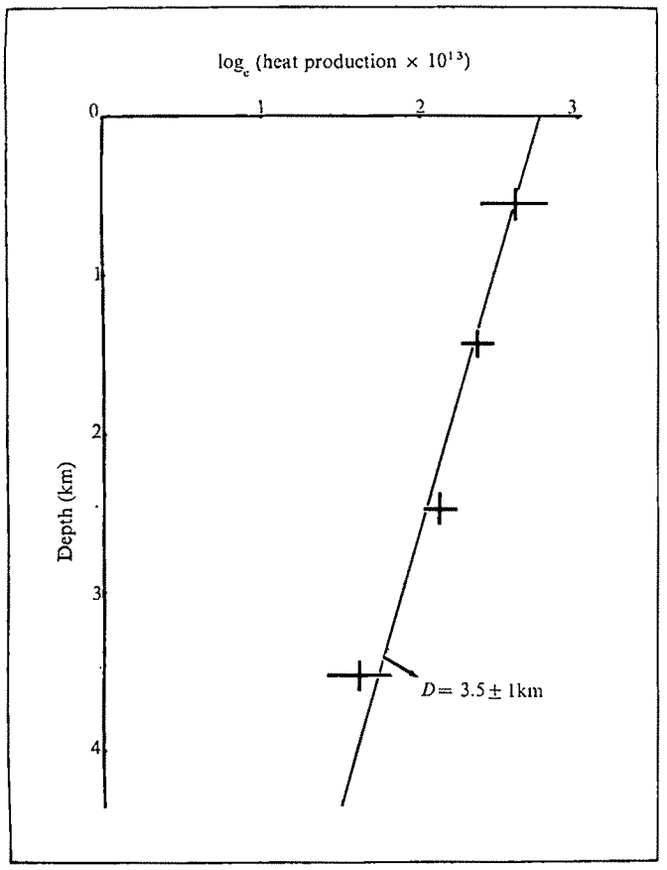

Fig. 2 Distribution of the values of $\log_e$ (mean heat production $\times 10^{13}$) for each of the four horizontal units, with depth in kilometres below the top of the basement complex. The values of mean heat production were calculated from the data in Fig. 1.

Furthermore, this value of D measured at the surface is unlikely to be true for all depths in the present Alpine crust. Recent geophysical work[8,9] suggests not only that the base of the crust below the Tauern Window is molten but also that below a depth of 10 km there is a large granitic body of assumed Alpine age. This will almost certainly have redistributed the radioactive elements in the lower crust, perhaps with another value of D.

Finally, the results presented here illustrate that the rate of decrease of heat production with depth may be more variable than was initially anticipated. The value of D presumably varies with the regional conditions under which fractionation and intrusion of magma took place. At this time, however, it is not possible to decide whether an exponential decrease of heat production with depth is the direct consequence of fractional crystallisation processes, or whether other factors, such as the effect of the gravitational field on the distribution of large ionic complexes[10], also contribute significantly.

The γ-ray spectrometry was carried out at the Mineralogisk-Geologisk Museum, Oslo at the invitation of Professor K. S. Heier. I thank him and his colleagues, P. Killeen and G. Raade in particular, for help and hospitality. I thank my supervisor E. R. Oxburgh, and also K. O'Nions, S. W. Richardson, M. J. Bickle, P. England and D. Waters for discussions throughout the project.

Iron and manganese encrustations in Recent sediments

Cores taken from the north-eastern Mediterranean (Fig. 1) during cruise 4/72 of the RRV *Shackleton*, using a Lehigh 4-inch hydroplastic gravity corer, contain layered organic structures encrusted with either manganese or iron minerals (Table 1, Fig. 2).

To our knowledge these encrustations have not previously been reported from seafloor sediments. The bulk of the manganese deposits, found in layers in the top 5–25 cm of the cores, occur on tubes, which we consider to be the agglutinating benthonic foraminiferan *Rhabdammina* (Fig. 3*a* and *b*). The deposit is also found on small branching rods (Fig. 3*d*) which are believed to be of organic origin but have not yet been identified. Smaller deposits are occasionally found on the shells of some of the pteropods and planktonic foraminifera (Fig. 3*c*); large tubes (Fig. 3*e*) are thought to be the encrusted linings of burrows. The iron deposits, present in layers beneath the manganese deposits, occur as encrustations on what seem to be mineralogically altered *Rhabdammina* tubes and, rarely, on planktonic foraminifera; no iron equivalent of the branching rods or large tubes has been found. When a core is

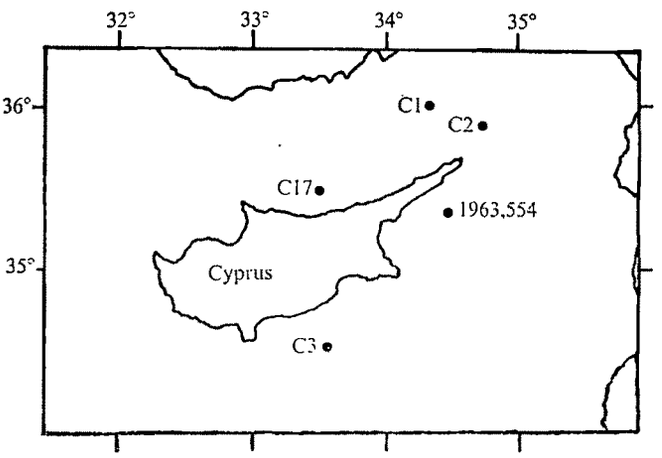

Fig. 1 Location of cores, C. C1, BM1973,0,1; C2, BM1973, 0,2; C3, BM1973,0,3; C17, BM1973,0,17. 1963,544 is a British Museum valve lead sample.

sectioned the manganese deposits appear as black streaks, and the iron-encrusted tubes can be seen as ochre coloured layers. Both types of encrustation were separated from the sediment by washing carefully with hydrogen peroxide (10 vol.), which disaggregates the clay minerals. The manganese encrustation was removed from the smaller tubes with a solution of 1 M hydroxylamine hydrochloride. This exposed a tube similar to the encrusted *Rhabdammina* found in the top 0–5 cm of the cores. The iron encrustation was removed with 1 M hydrochloric acid, leaving a

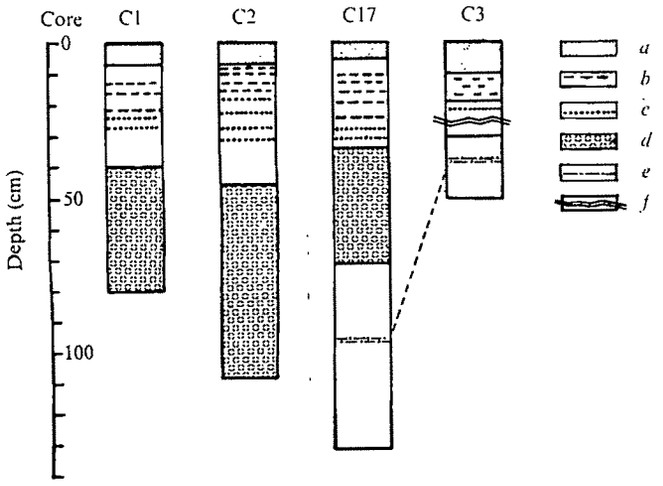

Fig. 2 Sedimentology of the cores. *a*, Orange-yellow ooze; *b*, layer of black manganese-encrusted tubes in light brown ooze; *c*, layer of brown iron-encrusted tubes in light brown ooze; *d*, grey ooze; *e*, light green layer in green-grey ooze (containing no benthonic foraminifera, and possibly representing a sapropel). Cooler water planktonic foraminifera occur below this level. *f*, position of hiatus.

siliceous tube similar to that produced when unencrusted *Rhabdammina* were similarly treated.

Examination by X-ray diffraction of the material rich in manganese showed that it was composed mainly of todorokite, a mineral commonly present in managanese nodules[1]. This analysis was confirmed by X-ray powder photography. The structural spacings which we have measured differ slightly from those previously reported[2], possibly because of the greater amount of magnesium in the structure. The nature of the material rich in iron is not known, but it is amorphous to X rays and is probably a hydroxide.

The faunal content of the cores indicates that they are post glacial. The planktonic foraminiferal population indicates a warm temperature and is dominated by *Globigerinoides ruber* (d'Orbigny), which makes up 60–90% of the samples larger than 250 μm. It is associated with many gastropods and pteropods, which indicate postglacial sediments in this region[3,4]. In core C17 below 100 cm, and in core C3 below 45 cm, the occurrence of the foraminiferal species *Globorotalia inflata* (d'Orbigny) and *Globigerina pachyderma* (Ehrenberg) provide evidence of cooler conditions. The sediments in core C3 seem to have been disturbed. The distinction between the layers of manganese-rich and iron-rich tubes is less apparent in this core, and the grey ooze section is missing (Fig. 2). A light green layer is present in green-grey ooze at 95 cm in core C17 and is also seen at 27 cm in core C3; this suggests that there is a hiatus somewhere between 20 and 30 cm in core C3, although no physical break is visible in the longitudinally sectioned core. The sedimentation rate in core C17, assuming that a date of 10,000 yr BP (ref. 5) represents the commencement of the postglacial period, is at least 13 cm per 1,000 yr. This implies that the manganese-rich horizons have an age range of about 770 to 2,000 yr BP.

Fig. 3 Manganese encrustations: *a*, Smooth surfaced *Rhabdammina* tubes (typically 0.2–1.2 mm in diameter, and greater than 3 mm long); *b*, *Rhabdammina* tubes with globular protuberances (typically 0.25–0.5 mm diameter, and more than 4 mm long); *c*, planktonic foraminiferan *Globigerinoides ruber* (d'Orbigny); *d*, branching rods (typically 0.075 mm diameter, length variable); *e*, large tube, probably a (?worm) burrow lining (typically 1 mm in diameter and 3 mm long).

Table 1 Chemical analyses of *Rhabdammina* tubes

	Unencrusted	Manganese-rich encrustations			Iron-rich encrustations
Core No.	C2	C3	C3*	C1	C2
Depth (cm)	0–4	15–16	15–16	12.5-14.5	20-21
Acid-soluble fraction weight (%)					
Mn	0.1	35.3	26.9	32.5	0.3
Fe	4.2	1.3	1.4	0.7	30.6
Ca	9.0	4.9	5.9	4.2	3.6
Mg	0.6	3.6	3.2	3.3	1.3
Insoluble SiO_2	67.8	14.5	19.7	< 14.9	11.3

*Globular protuberances.

The *Rhabdammina* tubes and other attendant organic debris seem to produce preferential surfaces for the deposition of manganese and iron, as the encrustations only occur in the *Rhabdammina* layers. The presence of the manganese-rich layers above the iron-rich layers may be related to the migratory processes believed to be responsible for the formation of manganese nodules[6–8].

We thank Miss E. Fejer for confirming the identification of todorokite by X-ray powder photography, the Captain and Officers of the Natural Environment Research Council RRV Shackleton, and Drs R. Chester and G. Evans, chief scientists for the cruise.

Photolysis of CO-NH_3 mixtures and the Martian atmosphere

One of the puzzling aspects of the Martian atmosphere is the absence of nitrogen or compounds containing nitrogen[1]. Instead, the atmosphere is found to be CO_2 along with smaller amounts of CO and H_2O. (ref. 1). One suggestion is that nitrogen

atoms gain sufficient energy to escape the gravitational field when N_2 undergoes photodissociation with ultraviolet light[2]. Alternatively, nitrogen may be conserved in compounds in the Martian crust[3].

We have already noted that although neither CO_2 nor H_2O affected the rate of NH_3 photolysis, CO acclerated the photodecomposition of ammonia, with the formation of a solid product[4]. We have investigated the photolysis of NH_3 in the presence of CO in greater detail not only because of the potential significance to atmospheric photochemistry on Mars but also because of the possibility of photocatalytic reactions of NH_3 and CO on the Martian surface[5] and in the interstellar medium[6]. These photochemical reactions may also have occurred on the primitive Earth[7].

Ammonium cyanate has been identified as the major product of the photolysis of gaseous NH_3–CO mixtures at wavelengths of 206.2 and 184.9 nm. This compound was probably not detected by previous workers because it sublimes readily at room temperature and atmospheric pressure (see refs 8-10). Urea and biurea were isolated in yields that were approximately 10% of the yield of ammonium cyanate and formamide, and the yields of semicarbazide, cyanide and biuret were about 10% of the yield of urea and biurea.

Water-soluble ^{14}C–organic compounds are formed on siliceous substrata which are irradiated in the presence of ^{14}CO, NH_3 and either N_2 or $^{12}CO_2$ diluent gas. For example, 119 nmol of ^{14}C–organics were produced when 0.5 g of vycor glass particles containing 0.28 mmol of adsorbed NH_3 were irradiated for 12 d in the presence of 250 mmol of CO, using an ultraviolet source which had spectral quality and intensity of the sunlight which reaches Mars. This synthesis occurs using an ultraviolet source with a wavelength of approximately 210 nm or greater than 250 nm. Little reaction was observed with dark irradiated samples or when the light source contained only wavelengths longer than 280 nm. Silica gel and volcanic ash shale were also used as substrata for the synthesis. Higher yields were obtained when the irradiations were carried out at −110° C. Substrata which were predried at 700° C or 400° C *in vacuo* were more effective than those which were predried at 150° C even though more NH_3 was absorbed by the latter. One factor responsible for these changes may be the level of water adsorbed on the substrata. Addition of water vapour to the gas mixture inhibits, but does not completely prevent, the formation of organic compounds.

Thin layer chromatography (TLC) and autoradiography provided tentative identification of ^{14}C–urea and showed it to be a major product. The identification was substantiated by eluting the suspected ^{14}C–urea spot from the TLC plates, and demonstrating that it was digested by urease. ^{14}C–urea was also detected on substrata which had been predried at 150° C, but TLC and hydrolysis indicated that formamide was the major product. ^{14}C–formaldehyde has been tentatively identified as a minor product on substrata which had been predried at 700° C or 400° C by the dimedon derivative procedure (ref. 11, and J. P. Ferris *et al.* not yet published). Using hot water extraction to remove the products from the substrata would have destroyed any ammonium cyanate.

In the experiments which used light with a wavelength of more than 250 nm the reactions were obviously catalysed by wavelengths longer than those absorbed by the gaseous reactants. The absorption coefficient for NH_3 is less than 10^{-4} cm^{-1} at 240 nm[11] whereas the longest wavelength at which CO shows any ultraviolet absorption is 206 nm (ref. 12). Thus the reactions are initiated by excitation and/or photolysis of the gas(es) which are adsorbed on the surface, by the longer ultraviolet wavelengths.

The findings discussed here indicate an additional possible mechanism of nitrogen conservation. If NH_3 is outgassed from the Martian crust it would be photolysed and would react with CO, yielding cyanic acid. The cyanic acid could well precipitate as ammonium cyanate which in turn would be converted to urea.

Surface reactions involving CO and NH_3 would also be compatible with conditions existing on Mars. The dust storms known to occur on Mars would expose large amounts of the surface to sunlight. Such dust storms could also effectively bury the particles, thus protecting the organic products from photodestruction.

If NH_3 has been outgassed during the recent history of Mars, it seems highly probable that the molecular analysis experiment on the 1976 Viking mission[13] will detect nitrogenous compounds, such as urea, in the Martian soil. If the Viking mission obtains evidence suggesting that life exists on Mars, a test for urease[14] may be useful in characterising metabolic processes in later Mars landings.

Both NH_3 and CO occur in interstellar space. CO is the most abundant compound detected in the Sagittarius and Orion nebulae[6]. Cyanic acid and formamide have also been identified in these nebulae[7] and it is therefore possible that these compounds were produced photochemically from CO and NH_3. The adsorption of these molecules on the surfaces of particles would increase the probability of reaction even though their concentrations in interstellar space are extremely low. Furthermore, the reactions could make use of the more abundant ultraviolet light at wavelengths of up to 250 nm. Our observation of an increased synthetic rate at low temperatures are also compatible with interstellar conditions. Recent experiments have suggested that the irradiation of silica gel in the presence of CO yields a silica ester of formic acid which may undergo further photochemical reactions with NH_3 to produce urea and formamide. It has also been demonstrated that ultraviolet light with long wavelengths (>250 nm) causes the formation of CO_2H and CO_2^- radicals from CO and silica gel[15]. The surface radicals produced were unusually stable at low temperatures. Thus the formation of formate ester and/or radicals on interstellar grains could provide stable conditions for subsequent reactions with NH_3.

There is some disagreement concerning the composition of the atmosphere of the early Earth. A highly reduced CH_4, NH_3 and H_2O atmosphere is preferred by some whereas others believe that a more oxidised CO_2, N_2 and H_2O atmosphere (with some more highly reduced compounds) is more likely[7]. In our view any ammonia in the primitive atmosphere would have been rapidly photolysed to N_2 and H_2. In the presence of CO formed by outgassing or by the photolysis of CO_2, the NH_3 could, however, have been efficiently converted to cyanate. Some of this cyanate would be hydrolysed back to CO_2 and NH_3, and some would be thermally converted to urea[16]. Some of it, however, may also have effected the formation of pyrimidines[17] and high energy phosphate bonds[18]. If these reactions were significant they probably occurred early in the history of the Earth. The rapid rate of the photolysis of ammonia limits the time period in which it would have been present in significant amounts on the early Earth[4]. The surface-dependent syntheses described here would be of questionable importance on the primitive Earth because of their susceptibility to inhibition by water. The reaction yielding formate, formaldehyde and other products[5,11] seems more likely to have occurred on the terrestrial surface if CO was indeed present.

Crystalline (xanthotoxin)$_2$.KI$_3$

STUDIES of the crystal structure of many organic and inorganic tri-iodides have shown that they are salts[1]. What happens when a tri-iodide salt forms a complex with a neutral, but polar, organic molecule? Examples, which are formed by related organic molecules, are (coumarin)$_4$.KI$_3$ (ref. 2) and (xanthotoxin)$_2$.KI$_3$ (ref. 3). (Xanthotoxin is 8-methoxy-3′,2′:6,7-furocoumarin). The crystals of the first of these substances show one-dimensional disorder[4] and its structure is not known; we have now determined the crystal structure of (xanthotoxin)$_2$.KI$_3$, which is fully ordered, and find that there are potassium cations, tri-iodide anions and neutral xanthotoxin molecules in the crystal. The structure were obtained: triclinic, $a = 9.59(1)$ Å; $b = 11.09(1)$ Å; $c = 7.96(1)$ Å; $\alpha = 118.1(1)°$; $\beta = 86.7(1)°$; $\gamma = 114.5(1)°$; space group $P\bar{1}$ (according to the structure analysis); $D_m = 2.11$ g cm^{-3}, $D_c = 2.11$ g cm^{-3} for 1 formula unit per cell.

Intensities of about 1,900 reflections were measured using a Stoe semi-automatic Weissenberg diffractometer (Mo Kα, graphite monochromator). Appropriate corrections were made for geometrical and absorption factors. The structure was solved by Patterson and Fourier methods and refined by least squares, using anisotropic temperature factors for all non-hydrogen atoms. The present R factor is 8.2%.

The crystal structure (Fig. 1)[7] can be conveniently described in terms of extended two-dimensional slices, one xanthotoxin molecule thick, which are bound by $(2\bar{2}0)$ and $(\bar{2}20)$ planes (Fig. 2). The bonding between these slices is by dispersion forces and is appreciably weaker than that within the slices, which results from ionic and dipolar interactions. Each slice is composed of stacks of xanthotoxin molecules, interleaved by columns of alternating cations and anions. The axes of both stacks and columns extend in the [001] direction. Within the xanthotoxin stacks the successive molecules are antiparallel, with an interplanar distance of 3.44 Å. In crystalline xanthotoxin[8] the stacks contain parallel molecules, with an interplanar distance of 3.58 Å. The shortening in the present compound is presumably because of dipole–dipole interaction between antiparallel molecules, in addition to the normal dispersion forces. There is also an appreciable cation–anion interaction in the [001] direction; each K^+ ion lies at the centre of a parallelogram formed by central and outer iodine atoms of tri-iodide ions above and below it along [001]. The distance of K^+ to the outer iodine is 3.53 Å, equal to the shortest K^+---I^- distance in crystalline potassium iodide[9], and to the central iodine 3.98 Å (the distance to the second outer iodine is 6.04 Å). The main interaction between stacks and columns is an ion–dipole interaction between K^+ ions and the methoxy and lactonic oxygens of the xanthotoxin molecules, with K^+--O distances of 2.75 and 2.88 Å respectively. These distances are similar to the K^+--O distances of 2.76 and 2.80Å found in potassium hydrogen bis (homophthalate)[10]. On the other hand the C--I distances between iodines of the I_3^- ion and the non-polar part of the xanthotoxin molecule, lie in the range 4.10–4.24 Å, showing that these are normal C–H---I contacts.

The dimensions of the xanthotoxin molecule are similar to those found in crystalline xanthotoxin[8], but the carbon atom of the methoxyl group is less rotated out of the mean plane

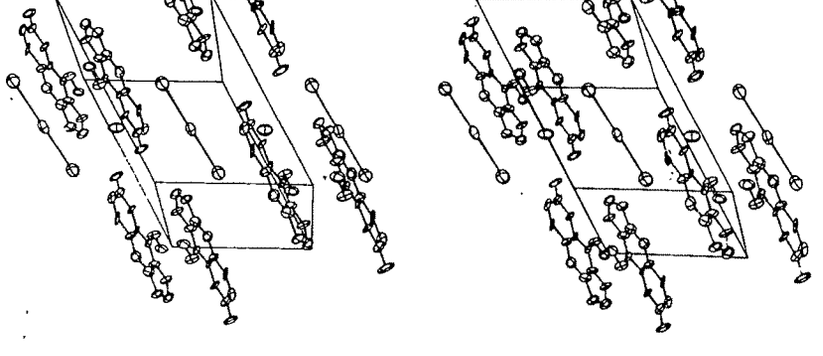

Fig. 1 An ORTEP[7] stereoview of the unit cell. The origin of the unit cell is at the centre of the parallelepiped. The stacks of xanthotoxin molecules run along the eight edges of the parallelepiped; a pair of xanthotoxin molecules in each of these stacks has been omitted to avoid complicating the diagram. The K^+ and I_3^- ions are both centred at centres of symmetry and the pairs of xanthotoxin molecules shown are related by centres of symmetry. Hydrogen atoms have been omitted.

is thus similar to those of other neutral molecule–salt complexes, such as (succinimide)$_2$.tetraethylammonium bromide[5]. Presumably (5,5-diethylbarbituric acid)$_2$.KI$_3$ has a similar structure but only a very brief report has appeared[6].

Strongly dichroic reddish-brown rhombs, somewhat elongated along [001] and showing (100) and (010) faces, were grown from ethanol. The following crystallographic results

of the furocoumarin moiety than in crystalline xanthotoxin (deviations from the mean plane are 0.27 and 0.94 Å respectively). The tri-iodide ion is centrosymmetric, with $d(I–I)=2.939(2)$ Å, a value similar to those found in other structures containing noninteracting I_3^- ions[1].

Thus (xanthotoxin)$_2$.KI$_3$ is a neutral molecule—salt complex, with the individual structural elements clearly discernible

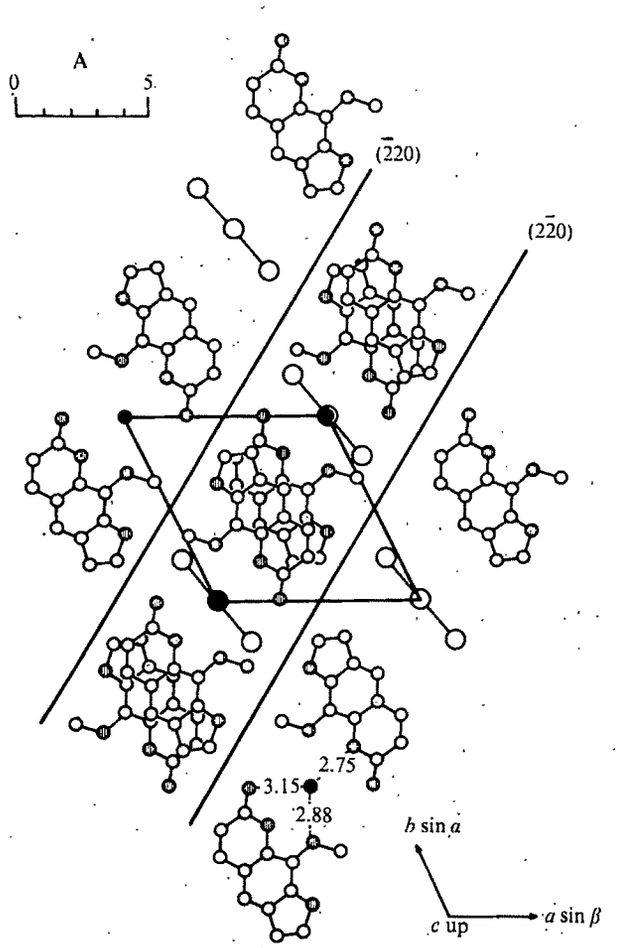

Fig. 2 The crystal structure seen in projection down [001]. An infinite two-dimensional slice, bounded by (22̄0) and (2̄20) planes and extending normal to the page, is shown. The shorter interatomic distances mentioned in the text have been included in the figure. Hydrogen atoms have been omitted. The slices on the edges of the figure each contain only a single layer of structural units so as not to complicate the diagram. Large open circles, iodine atoms; small open circles, carbon atoms; solid circles, potassium atoms; hatched circles, oxygen atoms.

the crystal. The mutual arrangement of these is such as to provide both local neutralisation of charge, the importance of which has been emphasised by Powell and Wait[5], and an antiferroelectric interaction in the stacks of dipolar xanthotoxin molecules.

New vapour deposition technique

THERE are various techniques of vapour deposition for putting down thin films, or thicker coatings and deposits of one material on another[1,2], which are of interest to a growing number of industries. The techniques range from chemical vapour deposition at relatively high gas pressure and temperature to physical vapour deposition based on thermal evaporation in a high vacuum for deposition on to hot or cold substrates. In recent years interest has grown in several intermediate techniques in soft vacuum (10^{-3} to 1 torr) which may be physical and/or chemical in nature[3-5]. Gas discharges are sometimes used to influence both the physical and chemical aspects of the process—to generate vapour by sputtering, to cause chemical reactions among vapour species, or to encourage bonding to the substrate. Here I outline the basic features of a new 'intermediate' technique which depends simply on evaporation into a heated gas. The aim is to cause the vapour species to diffuse to the substrate while avoiding conditions favouring homogeneous nucleation in the gas phase. Chemical reactions may or may not occur depending on the choice of gas and gas discharges can be employed for substrate cleaning, or other purposes if required.

Homogeneous nucleation within an ambient gas occurs readily at high concentrations of a vapour species and indeed has long been exploited for the manufacture of powders[1] (such as carbon black and pigments). It can readily occur in soft vacuum[6] and particularly fine powders can be made this way[7]. But its occurrence under vapour deposition conditions is

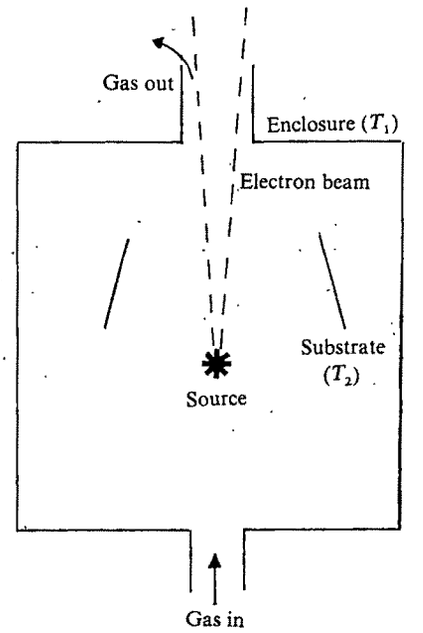

Fig. 1 Schematic diagram of apparatus.

usually undesirable since a poorly bonded granular deposit results. There have been several attempts to construct accurate theoretical models for homogeneous nucleation[8,9], though as yet no entirely satisfactory experimental verifications have been made. At least one investigator[10] thinks that the theoretical problem is beyond precise solution at present. But inspection of the theory reveals that the rate of formation of stable clusters should increase with vapour concentration, but decrease as the ambient temperature increases owing to an increase in the critical size for stable nuclei. Lydtin[11] showed how to raise the soot limit and consequent growth rate of pyrolytically deposited graphite by mechanical means for reducing the vapour concentration.

The vapour concentration C at any specified coordinates in a given geometry of source and sinks is, from the diffusion equation, proportional to the source strength S and inversely proportional to the diffusion coefficient D (which in turn is

proportional to the product of the average molecular speed c and the mean free path λ). Thus

$$C \alpha S/D \alpha S/(c\lambda) \alpha S/T^{3/2}$$

because of the dependence on temperature (T) of c and λ. Raising the gas temperature will reduce the vapour concentration and increase the size of stable nuclei. So it should be possible to find a range of operating conditions of gas temperature, pressure and rate of evaporation which avoids homogeneous nucleation and precipitates material in molecular form onto the substrates (light gases are favoured by virtue of a larger mean free path).

An experimental investigation of a technique based on these principles was made with apparatus the essential features of which are illustrated in Fig. 1. The heated enclosure was mounted within a soft vacuum chamber (10^{-2} to 1 torr). Electron beams generated by a glow discharge gun[12] were conveniently used for heating purposes. Dense deposits of ceramics (silica, alumina, magnesia, spinel, silicon nitride, titanium carbide and carbon), metals (aluminium, titanium, chromium and molybdenum) and a semiconductor (silicon) have been put down on a variety of substrates including glasses, ceramics, metals and, again, silicon. Several gases were investigated including hydrogen, helium, nitrogen, oxygen and argon and rates of deposition were typically in the range 10^{-2} to 1 mm h^{1}. At enclosure temperatures T_1 in the range 300° C to 600° C homogeneous nucleation was insignificant at gas pressures of $400/d$ mtorr, where d(cm) is the dimension of the enclosure (and therefore equivalent to several tens of mean free paths in a heavy gas such as argon). No investigation of the range of appropriate gas pressures has yet been made, except in the case of hydrogen, for which satisfactory deposits were still obtained at $4000/d$ mtorr and this is probably not an upper limit.

The structures of the deposits obtained were essentially similar to those well-known in chemical vapour deposition[1]. Depending on the substrate temperature T_2 and the properties of the source material, structures from amorphous through polycrystalline to single crystal were obtained. The bond to the substrate was dependent on chemistry and could sometimes be influenced by the chemical nature of the gas. The texture of deposits was dependent on the smoothness and cleanliness of the substrate surface. Stresses of well known character were found in the deposits, though in a general way the higher the substrate temperature T_2 the lower the grown-in tensile stress.

The advantages of the technique are several. Only roughing pumps are needed, at least for small-scale operations. The transport by diffusion results in good 'throwing power'[13]. The heating of the enclosure degasses the contents and thereafter purity is maintained by the flowing gas which, because of a relatively long and narrow exit orifice, prevents back diffusion of contaminants from outside. On the other hand the gas readily permits an electron beam (of 15–30 keV) to enter though any suitable method for vapourising the source, including sputtering, can be used. Since many of the parameters can be adjusted independently a high degree of process control is possible. The technique is readily adaptable to the deposition of alloys, complex compounds and multilayers and is compatible with other beam techniques for processing materials (such as welding, machining and ion implantation). In a general way it offers a versatile and reproducible method for fabricating special materials.

I thank Mr S. D. Ford for assistance and both he and Mr J. A. Desport for testing the conclusions in some practical applications.

dsDNA made by RNase-sensitive DNA polymerase from RSV-transformed cells

THE hypothesis that the RNA-directed DNA polymerase (reverse transcriptase) may function in normal cells[1] as part of the machinery for gene amplification is being investigated[2–8]. Cytoplasmic fractions of normal[6,7,9,10], neoplastic[11–14] and virus-transformed cells[3,15], contain RNase-sensitive DNA polymerase activities. Most studies revealed that cellular DNA polymerases differed greatly from the oncorna virus RNA-directed DNA polymerase[7,9] but the nature of the endogenous template of the cellular DNA polymerases was not described. In view of these findings and reports on the participation of RNA in DNA synthesis by DNA polymerases in bacteria[16–20], and mammalian[21–23] cell systems, we investigated the nature of the template and the role of RNA in the synthesis of DNA by the cytoplasmic RNase-sensitive DNA polymerase activity found in rat cells transformed by the B77 strain of Rous sarcoma virus (R(B77) cells). We found that such preparations contained DNA molecules which served as the template for the RNase-sensitive DNA polymerase activity. We also found that RNA has a function in the synthesis of DNA since nascent DNA molecules, covalently linked to RNA, were synthesised at the very beginning of the reaction.

R(B77) cells, a cell line of rat embryo fibroblasts transformed *in vitro* by the B77 strain of Rous sarcoma virus (RSV), were used[24,25]. The cells were maintained in culture by weekly transfers. The cells were seeded at a concentration of 5×10^5 cells per plastic Petri dish (diameter 90 mm; Nunc, Denmark) in 10 ml Eagle's medium containing 1 or 2 μCi ml^{-1} of 5-^{3}H-uridine (13.8 Ci mmol^{-1}; Nuclear Research Center, Negev, Israel) or 0.1—0.2 μCi ml^{-1} of 2-^{14}C-uridine (62 mCi mmol^{-1}; Radiochemical Centre, Amersham, England). The cultures were labelled for 24 h, unless otherwise stated. To label cellular DNA, the medium of R(B77) cells was replaced with fresh Eagle's medium containing 1 μCi ml^{-1} of methyl-^{3}H-thymidine (8.2 mCi mmol^{-1}: Nuclear Research Center, Negev). BUdR was incorporated into cellular DNA by adding 30 μg ml^{-1} of BUdR (Sigma) to the medium of R(B77) cells. The cells were labelled with ^{3}H-deoxycytidine (1 μCi mmol^{-1}; specific activity, 19.4 Ci mmol^{-1} Radiochemical Centre) and were collected after 48 h.

High speed pellets (HSP) of cells were prepared as described by Coffin and Temin[3]. The standard assay for the avian sarcoma RNA-dependent DNA polymerase was according to Temin and Mizutani[26], as described previously for purified B77 virions[15,27]. The DNA polymerase activity in HSP was studied under the same conditions as for the avian sarcoma virus enzyme.

High speed pellet (HSP) preparations from R(B77) cells contained a DNA polymerase activity which was markedly inhibited by RNase treatment before and after initiation of DNA synthesis (Table 1). This indicates that the synthe-

sis of DNA by the HSP DNA polymerase activity is RNA dependent. To rule out the possibility that HSP preparations contain RNase and DNase activities, ^{3}H-uridine and ^{3}H-thymidine labelled HSP preparations were incubated with or without exogenous nuclease. It was found that the labelled nucleic acids were not degraded after incubation for 60 min at 37° C (not shown).

Table 1 Effect of RNase on DNA synthesis by HSP DNA polymerase activity

Treatment of enzymatic reaction with RNase*	Time (min) 5	15	30
	^{3}H-TMP incorporated (c.p.m. per 25 μl)		
Untreated	1,310	2,050	2,215
Pretreated for 10 min	160	175	215
Treated at 0 time	390	500	660
Treated at 5 min	1,320	1,420	1,590

* The HSP preparation was divided in four portions:one was left untreated, the second was preincubated with RNase A (50 μg ml^{-1}) at 37° C, to the third RNase was added immediately before the initiation of the reaction, and to the fourth, RNase was added 5 min after initiation of DNA synthesis *in vitro*. The standard assay of Temin and Mizutani[26] was used. Duplicate samples were removed and the TCA-precipitable radioactivity was determined.

The polymerase activity was also characterised by studying the effect of addition of synthetic polynucleotides (Table 2), which can help to distinguish between cellular DNA polymerase and the RNA-directed DNA polymerase of oncorna viruses[28]. Addition of poly(rA)·oligo(dT) to HSP preparations only slightly stimulated incorporation of ^{3}H-TMP into DNA whereas it markedly stimulated the RNA-directed DNA polymerase of RSV and poly(dA)·poly(dT) stimulated ^{3}H-TMP incorporation by both enzymatic activities to the same level. In this respect, the HSP RNase-sensitive DNA polymerase resembles other DNA polymerases present in eukaryotic cells[7,8].

Analysis by zonal centrifugation of the DNA molecules synthesised *in vitro* by the HSP RNase-sensitive DNA polymerase showed that the product banded in the sucrose gradient (15–65% (w/v) for 3 h at 45,000 r.p.m. using rotor SW50.1 of the Beckman ultracentrifuge) with a sedimentation coefficient of about 10S. Analysis on a sucrose gradient of the HSP DNA synthesised *in vivo* showed DNA molecules sedimenting to the bottom of the sucrose gradient and two bands of labelled DNA, of which the major peak had a sedimentation constant of about 10S (not shown).

The DNA synthesised by HSP DNA polymerase activity during 1 min and 20 min incubation was analysed by chromatography on hydroxylapatite columns (Fig. 1*a*). The DNA synthesised *in vitro* was eluted from the hydroxylapatite columns by 0.25 M phosphate. Labelled DNA prepared from R(B77) cells had the same elution profile as the DNA synthesised *in vitro*. Cellular DNA was eluted before the ^{14}C-labelled HSV DNA (0.27 M phosphate) at the position of nuclear DNA. This demonstrated that the DNA molecules synthesised *in vitro* are double-stranded and resemble nuclear DNA in their elution properties. There was no difference between the DNA molecules synthesised during a short (1 min) or a long (20 min) period.

To study the effect of actinomycin D on DNA synthesis by the HSP DNA polymerase, actinomycin D (250 μg ml^{-1}) was added to the standard reaction mixture which was then incubated for 20 min at 37° C. After extraction the DNA product was compared with DNA synthesised by HSP in the absence of inhibitor. Actinomycin D inhibited DNA synthesis by 80% compared with the untreated control. The DNA product synthesised by the HSP treated with actinomycin D was analysed by chromatography on a hydroxylapatite column. It was found (Fig. 1*b*) that this DNA was eluted by 0.25 M phosphate, similarly to the cellular double-stranded DNA (dsDNA) molecules. The HSP DNA polymerase activity differs from Rous sarcoma virus reverse transcriptase, in respect of the effect of actinomycin D (Fig. 1*c*). In the presence of actinomycin D, the viral enzymatic activity synthesises single-stranded DNA (ssDNA) molecules which are eluted from hydroxylapatite by 0.1 M phosphate.

High speed pellets were prepared from R(B77) cells, labelled or unlabelled for 48 h with ^{3}H-deoxycytidine and incubated in the presence or absence of BUdR. The DNA was extracted with phenol and banded in CsCl gradients (Fig. 2*a*). Untreated DNA banded at a density of 1.70 g ml^{-3} whereas the BUdR-containing DNA banded at the density of 1.74 g cm^{-3} (Fig. 2*d*). Samples from two unlabelled HSP preparations (prepared from cells grown in the absence or presence of BUdR) were incubated *in vitro* for 60 s under conditions of DNA synthesis with the four deoxyribonucleoside triphosphates (including ^{3}H-TTP). The DNA was extracted and banded in CsCl gradients. The DNA synthesised *in vitro* in the HSP from untreated cells banded at a density of 1.70 g cm^{-3} (Fig. 2*b*), the density of cellular DNA. The radioactive DNA synthesised *in vitro* in the presence of BUdR-containing DNA (HSP from BUdR-treated cells) partly banded at the density of the BUdR-labelled DNA and part was shifted to a smaller density (Fig. 2*e*). Longer incubation of the BUdR-containing DNA from HSP (5 min) resulted in a further shift to a lower density (Fig. 2*f*), similar to untreated DNA (Fig. 2*c*). These results demonstrate that the DNA polymerase activity present in the HSP utilised the DNA molecules present in the HSP as the template. The complete inhibition of this reaction by RNase suggests the involvement of RNA as a primer or an intermediate during DNA synthesis by the HSP DNA polymerase.

High speed pellet preparations were incubated under conditions of DNA synthesis and the processes were stopped at 1 min and 5 min after the initiation of the enzymatic reaction. The ^{3}H-TMP labelled DNA synthesised *in vitro* was extracted with phenol, precipitated by ethanol, resuspended in Tris-EDTA buffer, and divided into three: one portion was left as native DNA, the second was heat denatured, and the third was denatured by alkali, and each sample was banded in a Cs_2SO_4 gradient. Most of the native DNA product banded at the density of dsDNA (1.42 g cm^{-3}) but some radioactive DNA appeared at higher densities (1.58–1.69 g cm^{-3}) which are those of DNA molecules complexed or associated with RNA. The amount of DNA in this region, slightly increased after heat denaturation, but the radioactivity disappeared after treatment with alkali. Similar results were found with the DNA synthesised during a reaction period of 5 min. We then investigated the nature of the DNA molecules synthesised during the shorter reaction times, 7, 15, and 30 s (Fig. 3). Analysis of the 7-s DNA product (Fig 3*a*) revealed DNA molecules banding throughout the gradient, mostly at the densities of dsDNA (1.42 g cm^{-3}) and RNA (1.69 g cm^{-3}). The DNA molecules which initially banded at the density of RNA (1.69 g cm^{-3}), most probably DNA:RNA hybrid molecules, were not detected in Cs_2SO_4 after heat denaturation or alkali treatment ((Fig. 3*b* and *c*). Analysis of the DNA molecules synthesised during 15 or 30 s revealed that the total amount of native heavy DNA (which banded at 1.69 g cm^{-3}) was greatly decreased (Fig. 3*d* and *g*). After heat denaturation, however, the amount of radioactive DNA which appeared in the Cs_2SO_4 gradient between the DNA and RNA, most probably DNA–RNA complexes (1.58–1.69 g cm^{-3}) also increased (Fig. 3*e*). The same findings were obtained with the DNA product of a 30-s reaction (Fig. 3*g* and 3*h*). These reaction products disappeared on treatment with alkali after which the labelled molecules accumulated in the position of ssDNA (Fig. 3*f* and *i*). In all nine experiments carried out there was a significant increase of radioactivity in the region of RNA–DNA complexes after heat denaturation which disappeared after alkali treatment. This

indicates that part of the newly synthesised DNA molecules may be linked to RNA molecules. After a short incubation (7 s) the DNA molecules may have been synthesised on RNA molecules, which serve as templates or initiators. The labelled native DNA molecules, band at the density of dsDNA (1.42 g cm^{-3}) although some of it might still be covalently bonded to RNA and can be detected after heat denaturation.

The presence of an RNase-sensitive DNA polymerase activity in normal and transformed cells, which differ from the oncorna virus RNA-directed DNA polymerase, has recently been reported[3,6,7,9,10,15]. Our study confirms the presence of an RNase-sensitive DNA polymerase activity in R(B77) cells. The novel finding of this study is the demonstration that the HSP of R(B77) cells contains 10S DNA molecules of cellular origin which act as the template for this enzymatic activity and that RNA molecules also participate in the synthesis of DNA.

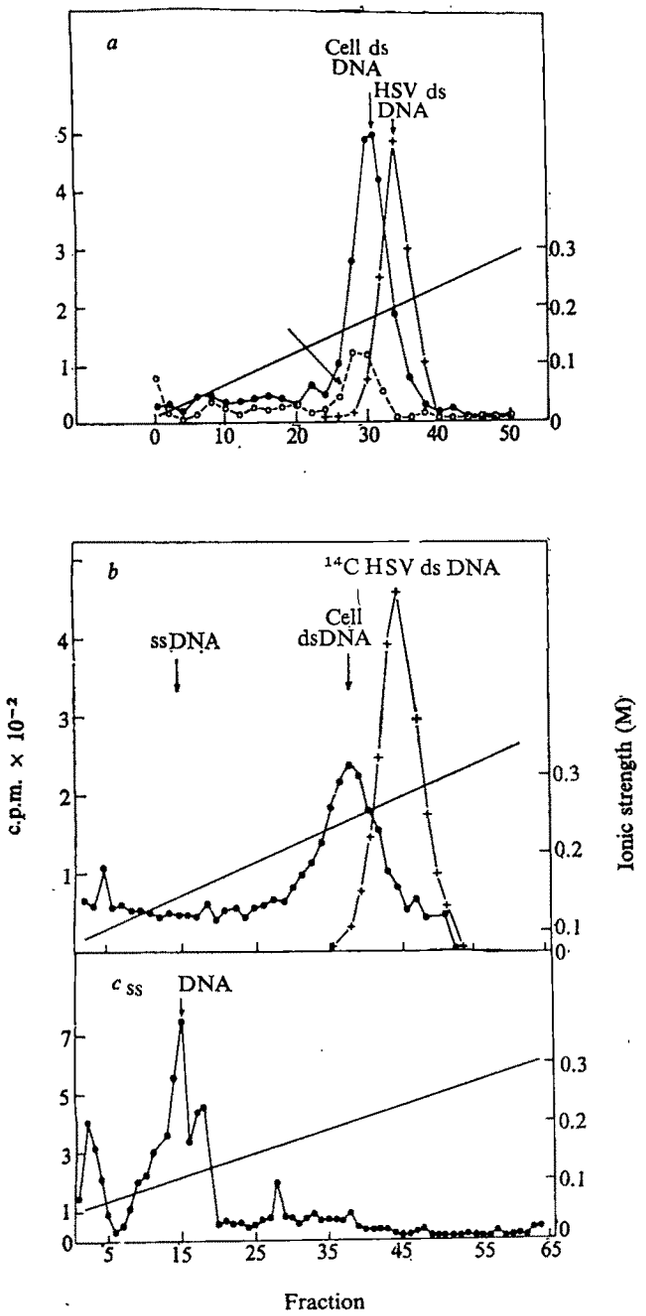

Fig. 1 Hydroxylapatite chromatography of DNA molecules synthesised by HSP DNA polymerase and Rous sarcoma virus reverse transcriptase in the absence and presence of actinomycin D. *a*, HSP was incubated with the standard reaction mixture and samples were removed at 1 and 20 min, treated with 1% SDS, the DNA was extracted with phenol and characterised by chromatography on hydroxylapatite columns (Bio-gel HTP; Bio-Rad Laboratory, Richmond, California), eluted with a linear gradient ranging from 0.05 M to 0.35 M of sodium phosphate (total volume 100 ml) and collected in about 40 fractions. TCA precipitable radioactivity in each fraction was collected on filters and counted in a liquid scintillation counter. Purified herpes simplex virus (HSV) DNA, labelled with ^{14}C-thymidine as well as BSC_1 DNA and HeLa DNA were used as markers. The results of three columns are combined in the graph. O, DNA molecules synthesised by a HSP preparation during 1 min; ●, DNA molecules synthesised by a HSP preparation during 20 min; +, ^{14}C-HSV DNA marker. The position of cell DNA is indicated by the arrow. *b*, An HSP preparation was incubated with actinomycin D (250 μg ml^{-1}) and the ^{3}H-TMP labelled DNA was phenol extracted and chromatographed on a hydroxylapatite column. ^{14}C-HSV DNA and cellular dsDNA served as markers. ●, ^{3}H-DNA synthesised by HSP enzymatic activity in presence of actinomycin D; +, ^{14}C-HSV DNA marker. Cell DNA eluted identically to HSP DNA. *c*, Viral reverse transcriptase activity. Purified B77 virions were disrupted with Nonidet P-40 and incubated *in vitro* under conditions of DNA synthesis by the viral reverse transcriptase, actinomycin D (250 μg ml^{-1}) was added and the ^{3}H-DNA molecules synthesised during 20 min were extracted by phenol and analysed by chromatography on a hydroxylapatite column [27,30] (●).

Table 2 Effect of poly(A)·oligo(dT) and poly(dA)·poly(dT) on DNA synthesis by the RNase-sensitive DNA polymerase activity from transformed R(B77) cells and the B77 Sarcoma virus reverse transcriptase activity

Pretreatment† of HSP	Polymer added	^{3}H-TMP incorporated (c.p.m.)* R(B77) enzyme	Viral‡ enzyme
Exp. 1 Buffer	None	1,887	1,871
RNase	None	365	ND§
Buffer	Poly(A)·oligo(dT)	2,310	126,540
Exp. 2 Buffer	None	1,145	5,551
Buffer	Poly(dA)·poly(dT)	2,193	10,245

* The standard assay for oncorna virus RNA-dependent DNA polymerase and HSP DNA polymerase activity was according to Temin and Mizutani[26]. To each reaction mixture, 0.01 $A_{260\ nm}$ units of poly(dA)·poly(dT) or poly(A)·oligo(dT) (Collaborative Research, Waltham, Massachusetts) were added.

† The enzyme preparations were incubated for 15 min at 37° C with RNase (50 μg ml^{-1}) or buffer before the addition of the standard reaction mixture. ‡ B77 virus treated with NP-40. § Not done.

The DNA polymerase activity present in HSP resembles the oncorna virus-associated reverse transcriptase in its sensitivity to RNase and in its ionic requirements[3,15]. Nevertheless, marked differences were found between the two enzyme activities in agreement with the findings of Bobrow *et al.*[9] and Kang and Temin[7]. We demonstrated that (a) the HSP enzyme was only slightly stimulated by poly(rA)·oligo (dT) which stimulates the viral enzyme, whereas poly(dA)·poly(dT) had the same stimulatory effect on both HSP and the viral enzymes; (b) the main product of the HSP RNase-sensitive DNA polymerase is dsDNA even after a very short reaction; (c) although actinomycin D inhibits both enzymes, only with the viral enzyme is there an accumulation of ssDNA molecules (Fig. 2); and (d) the endogenous template for the cellular RNase-sensitive DNA polymerase is DNA (Fig. 3), whereas for the viral enzyme, it is RNA. These results show that the HSP DNA polymerase activity is an RNA-dependent DNA polymerase, which utilises the cellular dsDNA molecules present in HSP as template.

What is the function of RNA during the synthesis of DNA? Analysis in Cs_2SO_4 density gradients of the DNA

products resulting from very short reactions revealed radioactive DNA banding at the density of RNA (1.69 g cm^{-3}) as well as labelled DNA molecules which banded as dsDNA. Radioactive DNA also banded at densities ranging from that of RNA to DNA (1.69–1.58 g cm^{-3}) suggesting that the DNA molecules are attached to RNA molecules. The amount of label which appeared in these regions, increased after heat denaturation and shifted to the density of ssDNA after alkali treatment, proving that they are DNA molecules linked covalently to RNA chains (Fig. 3) which initially banded together with the dsDNA molecules. It is possible that the RNA–DNA complexes described here resemble the RNA–DNA pieces described

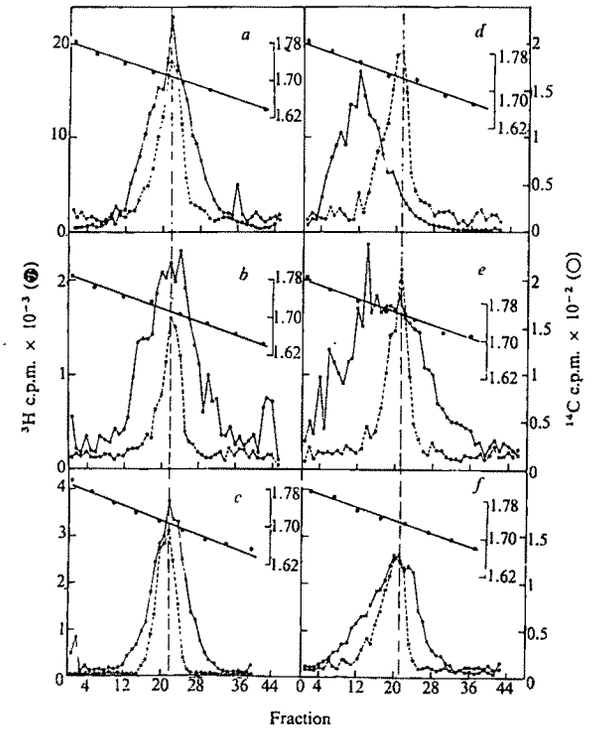

Fig. 2 HSP DNA as template for the endogenous RNase-sensitive DNA polymerase. Twelve Roux bottles containing R(B77) cells were incubated for 48 h in the presence or absence of BUdR (5-bromo-2′-deoxyuridine). One Roux bottle from each group was labelled with 1 μCi ml^{-1} of ^{3}H-deoxycytidine. After incubation, HSP was prepared. Unlabelled BudR-treated and control HSP preparations were incubated for 1 min and 5 min with the reaction mixture, and the reactions were stopped by addition of SDS to final concentrations of 2%, 0.5% Baycovin, and 50 μg of yeast DNA. The nucleic acids from all preparations were extracted according to the Hirt method, modified by Kang and Temin[10]. The alcohol precipitates and marker ^{14}C-thymidine labelled DNA from BSC_1 cells were added to 8 ml of a CsCl solution and the mixtures centrifuged for 60 h at 35,000 r.p.m. in the Beckman 50 Ti rotor at 22° C. The gradients were collected and the radioactive TCA precipitates counted. Densities were determined by weighing 100 μg samples (●). *a*, R(B77) cells were labelled with ^{3}H-deoxycytidine for 24 h after which the DNA was extracted (●). ^{14}C-thymidine labelled R(B77) nuclear DNA was used as a marker (○). The DNA preparations were mixed and analysed by centrifugation in a CsCl gradient. *b* and *c*, HSP preparations were prepared and incubated *in vitro* under conditions of DNA synthesis in the presence of ^{3}H-TMP. The ^{3}H-DNA was extracted with phenol after 1 min (*b*) and 5 min (*c*) reaction periods. The ^{3}H-TMP labelled DNA (●) was mixed with ^{14}C-thymidine labelled BSC_1 dsDNA (○) and centrifuged in CsCl gradients. *d*, R(B77) cells were incubated with BUdR and ^{3}H-deoxycytidine for 24 h. The DNA was extracted (●) and mixed with ^{14}C-thymidine labelled DNA (○) and centrifuged in a CsCl gradient. *e* and *f*, HSP preparations were prepared from R(B77) cells incubated for 24 h with BUdR. The HSP was incubated for 1 min (*e*) and 5 min (*f*) under conditions of DNA synthesis in the presence of ^{3}H-TTP. The DNA was extracted with phenol (●) mixed with ^{14}C-DNA (○) and centrifuged in gradients.

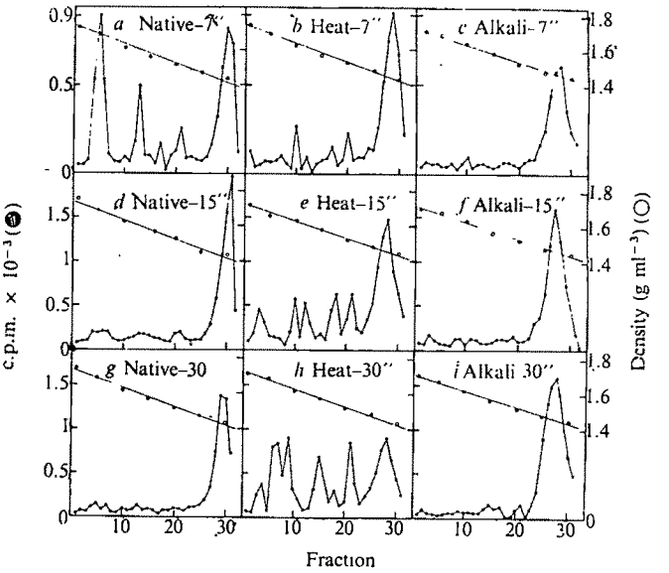

Fig. 3 Charcterisation of the DNA molecules synthesised by HSP DNA polymerase activity. HSP was incubated at 38° C for 7, 15, and 30 s with the standard reaction mixture. The reaction was stopped by adding SDS, and the DNA products were purified as described in the legend for Fig. 2. The DNA samples were resuspended in Tris–EDTA buffer and each DNA preparation was divided into three: one was left untreated (*a*, *d*, and *g*), one sample of each was boiled for 10 min and chilled immediately (*b*, *e*, and *h*), and the third sample was treated with 0.25 M NaOH for 10 min and then neutralised by HCl in ice (*c*, *f*, and *i*). All nine DNA preparations were mixed with Cs_2SO_4 to a final volume of 6 ml and centrifuged at 45,000 r.p.m. for 64 h at 22° C in the 50 Ti rotor of the Beckman centrifuge. The gradients were fractionated dropwise, the densities determined by weighing 100 μl of the indicated samples, and the TCA radioactive precipitates were counted. ●, Radioactive DNA; ○, density.

by Sugino, Hirose, and Okazaki[18]. The participation of RNA in DNA synthesis has also been suggested for mammalian cells[23] and for polyoma virus[29]. The presence of labelled DNA molecules after 7 s of DNA synthesis which band at a density of RNA (1.69 g cm^{-3}) (Fig. 3*a*) and disappear after heat denaturation (Fig. 3*b*) may indicate DNA synthesis on an RNA template, an activity ascribed to oncorna virus reverse transcriptase[7,26]. It is possible that low levels of reverse transcriptase activity may be detected only after a very short reaction period, whereas the major DNA polymerase activity in HSP of R(B77) cells is a DNA polymerase activity which requires RNA for its function, most probably as an initiator and not as a template. The role of this enzyme and its DNA template in the R(B77) transformed cell is still to be studied.

The study was supported by grants from the Leukemia Research Foundation, Chicago, Illinois; the Behr-Lamsdorf Foundation, Switzerland-Israel; and the Israel Cancer Association. We thank Gideon Eynav for technical assistance, Eynat Weinberg and Udy Olshevsky for suggestions and comments, Professor Edward Simon (on Sabbatical from Purdue University, Lafayette, Indiana) for reading the manuscript and Esther Russ for typing the manuscript.

RNA-dependent RNA synthesis in rat brain

RIBONUCLEIC acid-dependent RNA polymerase (replicase) was first isolated from *Escherichia coli* infected with RNA bacteriophage Qβ which has specific template requirements[1]. Such an enzyme has been described in tumour cells and several types of mammalian cells infected with RNA viruses[2–5].

It has been reported that in the normal mammalian cell polyribonucleotides are synthesised by a nontranscriptive process and enzymes which polymerise ATP to poly(A) have been found[6–8]. Ribonucleoprotein particles isolated from rat liver nuclei polymerise ATP, UTP, GTP and CTP to the corresponding ribohomopolymers[9]. These reactions have been suggested to be post-transcriptional additions to heterogeneous nuclear RNA. The microsome fraction of rat liver also incorporates the four ribonucleotides into polyribonucleotides a reaction which is stimulated by RNA but not DNA[10]. We report here the isolation of an enzyme fraction from rat brain which can synthesise RNA[12], both as a heteropolymer or a homopolymer, only when provided with a suitable RNA template or primer.

The enzyme fraction was isolated from rat brain (see legend to Table 2) and its RNA polymerase activity was measured by the radioactivity incorporated into acid-insoluble product from ^{3}H-UTP after incubation in various modifications of the standard assay medium (see legend to Tables 1 and 4). The reaction product satisfied the standard tests for RNA (Table 2). The reaction clearly depended on the presence of RNA, the amount of incorporation increasing linearly to a maximum as the concentration was increased (Fig. 1). Magnesium ions were also necessary, the optimum concentration of $MgCl_2$ being 12 mM. Only the four ribonucleoside triphosphates (NTPs) and not the corresponding deoxyribonucleoside triphosphates (dNTPs) could act as substrates. With enzyme from adult rats the omission of any one NTP from the medium markedly reduced incorporation (Table 1*a*) indicating that when they were all present the product was mainly heteropolymeric RNA. By contrast, the fraction from newborn rat readily synthesised RNA when provided with only a single NTP substrate (Table 1*b*): presumably this was

Table 1 Characterisation of the reaction in the presence of four ribonucleoside triphosphates

Where indicated 10 μg of DNase, 10 μg of RNase or 2 μg of actinomycin D was added, and one of the four ribonucleoside triphosphates was omitted. 3 NTP indicates the three ribonucleoside triphosphates other than the tritiated one. *a*, Enzyme and RNA were from adult brain; *b*, enzyme and RNA were from newborn brain (1-d-old). The standard reaction mixture had a total volume of 0.25 ml and contained 22 μmol Tris-HCl (*p*H 7.4), 3.0 μmol $MgCl_2$, 4.5 nmol 2-mercaptoethanol, 0.2 μmol each of ATP, CTP, GTP and ^{3}H-UTP (4×10^6 c.p.m. per 0.2 μmol): when assaying adult brain there was 80 μg enzyme protein and 10 μg template RNA; for newborn brain the quantities were 34 μg and 15 μg respectively. The reaction mixture was incubated at 37° C for 10 min for adult enzyme and 20 minutes for newborn enzyme, unless otherwise indicated. The reaction was stopped by addition of pyrophosphate and trichloroacetic acid. Precipitates were collected on membrane filters, washed eight times with cold 5% trichloracetic acid, and dried according to standard procedures[1]. In some experiments the reaction was stopped by blowing aliquots of the assay mixture on filter paper treated with pyrophosphate which was then washed for 2 h in 5% cold trichloroacecti acid according to the method of Bollum[18]. The radioactivities of the dried membrane filters or filter papers were determined in 10 ml of toluene scintillator containing 0.5% (w/v) of 2,5-diphenyloxazole with a Beckman LS 100 liquid-scintillation spectrometer. The radioactivity for zero time was subtracted from each value.

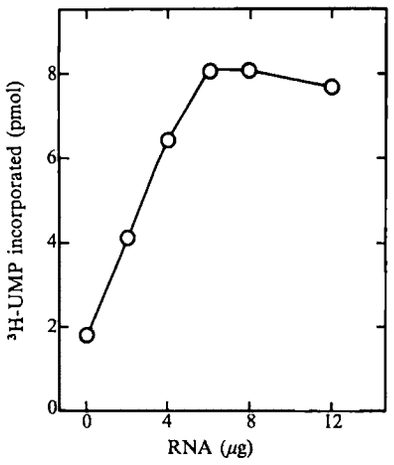

Fig. 1 Dependence of incorporation on concentration of template RNA. The composition of the incubation mixture was the same as described in Table 1 except for the RNA concentration, which varied. RNA and enzyme were from adult rat brain. Incubation was for 10 min.

nearly all homopolymer. When this homopolymer synthesis was investigated it was found, as reported for many other similar systems, that uptake of ^{3}H-UTP was inhibited by the presence of CTP or GTP (Table 4). It is therefore probable that with enzyme from newborn rats presented with all four NTPs nearly all the product was heteropolymer and *a fortiori* for the adult. It was clear that heteropolymer synthesis could be studied more easily using the adult enzyme fraction and homopolymer synthesis using the newborn and we did this, further improving the differentiation by using different concentrations of $MgCl_2$ in the reaction mixtures.

When the added RNA was omitted from the standard assay medium the incorporation fell to about one quarter. Most of this residual activity could be abolished by the addition of RNase which indicates that this also was mainly RNA-dependent RNA synthesis. The reaction was little affected by the addition of 10 μg of DNase and was inhibited by ammonium sulphate at concentrations which augment DNA-dependent RNA synthesis[13,14] (Table) 1. Two micrograms of actinomycin D had no effect. The effectiveness of various nucleic acids as templates was examined by substituting them for the rat brain RNA in the medium (Table 3). Only RNA was effective: DNA from calf thymus produced very little result. RNAs from Qβ, MS2 or GA phages, representatives of different groups of viral RNA, were ineffective and so were tRNA and rRNA from *E. coli* and TMV RNA. Of the homopolymers, poly(A), poly(G), poly(C) and poly(U) only poly(U) had any effect: either the synthesis was occurring by replication or by addition of UMP only to UMP terminals. Rat liver RNA was quite effective but markedly less so than the rat brain RNA. The degree of template specificity, that is, the range of effectiveness of the templates, was similar to that of the RNA-dependent RNA polymerases isolated from leukaemia and ascites tumour cells by Haruna *et al.*[5]. In the case of RNA replicase (RNA-dependent RNA polymerase) isolated from *E. coli* infected by Qβ phage, a basis for recognition of an RNA by an RNA replicase has been postulated by Kamen *et al.*[15] and Nishihara *et al.*[16]. Analysis of the brain RNA by sucrose gradient centrifugation gave the normal pattern for total cell RNA. Under these heteropolymer-promoting conditions the RNA polymerase in the enzyme fraction isolated from newborn rats had properties qualitatively similar to those for the adult but its activity was about three times higher (see Table 1 and Figs 1 and 2; it should be noted that the concentrations of enzyme and RNA differed from those used for the adult). ^{3}H-UTP was incorporated by the adult enzyme at an almost constant rate for the first 10 min of incubation with the template RNA (Fig. 2). During the next 10 min of incubation the rate declined. In the absence of added RNA the incorporated radioactivity reached a steady level after ~ 5 min incubation. With enzyme from newborn rat the activity increased linearly with time up to 30 min (Fig. 2). The maximum activity increased with increasing concentrations of enzyme. An explanation for the differences in time courses is that the adult enzyme fraction was contaminated by RNase or some inhibitor.

Table 2 Effects of nuclease and alkaline treatment on the product of the adult enzyme reaction.

Treatment	^{3}H-UMP incorporated (pmol)
None	9.1
Alkaline hydrolysis (0.3 N KOH; 37° C 18 h)	0.3
RNase 10 μg per 0.25 ml	1.0
DNase 10 μg per 0.25 ml	7.9

Reaction mixtures were as in the legend to Table 1. For the alkaline treatment, after 10 min incubation, sodium dodecyl sulphate and KOH were added to give final concentrations of 0.4% (w/v) and 0.3 N and the mixture was incubated at 37° C for a further 18 h. Ten micrograms of RNase or 10 μg of DNase was added to the incubation mixture after 10 min and incubation continued for a further 10 min. The reaction was terminated by addition of pyrophosphate, 50 μg of carrier albumin and trichloracetic acid. In the case of KOH addition, sodium dodecyl sulphate was added to avoid the degradation of product RNA by RNase contaminant in the enzyme fraction. Adult and 1-d-old rat brains were used to prepare enzyme fraction. Isolated brains containing cerebrum and cerebellum were frozen and thawed once. The brains were minced and suspended in medium (0.1 M Tris-HCl (*p*H 7.4), 0.01 M $MgCl_2$ and 0.5 mM 2-mercaptoethanol) containing 5 μg DNase lm^{-1}. The mixture, after homogenisation for 40 s, was stirred at 4° C for 30 min. The homogenate was centrifuged at 12,000*g* for 30 min and EDTA added to the supernatant to a final concentration of 10 mM. This solution was then centrifuged for 30 min at 12,000*g*. An equal volume of saturated ammonium sulphate (*p*H 7.4) was added to the supernatant and incubated at 0° C for 10 min and the 50% saturated ammonium sulphate-precipitable fraction was collected by centrifugation at 9,000*g* for 10 min and dissolved in medium (0.4 M ammonium sulphate, 9 mM Tris-HCl (*p*H 7.4), 4.5 mM $MgCl_2$ and 0.45 mM 2-mercaptoethanol). 0.2 volume of glycerol was added to the medium. This was the enzyme fraction. Its protein concentration was 16–28 mg ml^{-1} and it was stored at −80° C.

When presented with a single NTP the enzyme fraction from newborn rats synthesised considerable amounts of homopolymer, UTP and ATP being taken up to higher concentrations than GTP (Table 1*b*). Tests made to investigate heteropolymer synthesis by adult enzyme were repeated (Table 4) and showed that poly(U) synthesis was also independent of DNA and the presence of rat brain RNA as a primer was sufficient. It differed

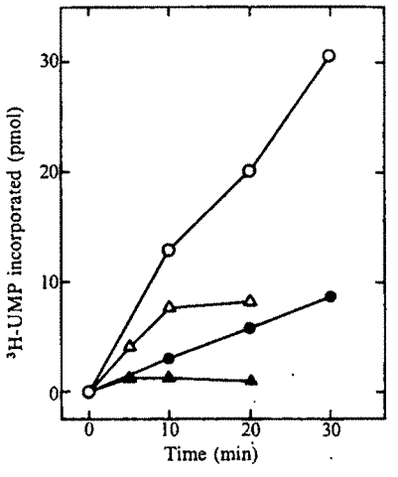

Fig. 2 Time course of RNA synthesis. The reaction mixture and conditions were the same as described in the legend to Table 1. Enzyme and RNA from newborn rat brain: ○, +RNA; ●, −RNA. Enzyme and RNA from adult rat brain: △, +RNA; ▲, −RNA.

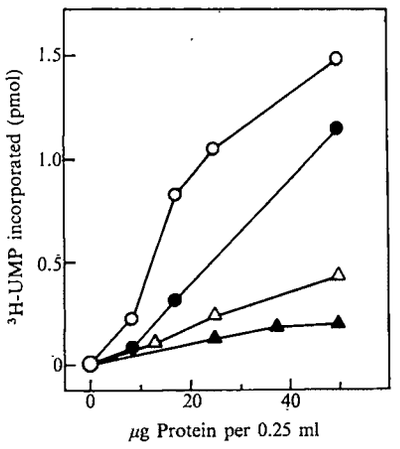

Fig. 3 Dependence of incorporation on concentration of enzyme protein (homopolymer synthesis). Conditions of assay were those described in the legend to Table 4 except for 5 μg of RNA of either adult or newborn brain and 10 minutes incubation. ○, Newborn enzyme with newborn RNA; ● newborn enzyme with adult RNA; △, adult enzyme with newborn RNA; ▲, adult enzyme with adult RNA.

from newborn enzyme in that the optimum $MgCl_2$ concentration was lower, about 4 to 6 mM. The formation of poly(U) may occur either by addition to poly(U) sequences in the template or by terminal addition to an RNA primer. Poly(U) was much more effective as a primer than poly(A) or poly(C), and poly(G) actually inhibited the residual synthesis occurring in the absence of added primer (Table 4). This means that if there was terminal addition it had strict primer requirements. When primed by the same primer RNA the activity of the newborn enzyme was several times higher than that of the adult (Fig. 3).

Table 3 Effect of various nucleic acids offered as template for RNA synthesis by adult enzyme

	Template (μg per 0.25 ml)		^{3}H-UMP incorporated (pmol)
Experiment 1	Brain RNA	10	8.9

	rRNA	6	2.3
	Calf thymus DNA	7.5	2.8
	−RNA		1.8

Conditions of assay were those described in the legend to Table 1 except that various nucleic acids were used as templates. Qß phage RNA, MS2 phage RNA and GA phage RNA were prepared in our laboratory by the procedure described by Haruna and Spiegelman[1]. TMV RNA, tobacco mosaic virus RNA was kindly supplied by Dr Y. Okada (Tokyo University). RNA was isolated from brains (cerebrums and cerebellums) of adults and 1-d-old Wistar rats. Fresh brain was cut up with scissors and stirred for 30 min at 4° C in a solution containing 0.1 M Tris-HCl (*p*H 7.4) 10 mM $MgCl_2$, 0.5 mM 2-mercaptoethanol, 5 μg ml^{-1} DNase and 0.4% (w/v) sodium dodecyl sulphate and incubated at 20° C for 8 min. An equal volume of phenol saturated with cold water was added and shaken vigorously for 15 min at 4° C. After centrifugation at 12,000*g* for 15 min, the upper aqueous phase was mixed again with an equal volume of water-saturated phenol. Phenol treatment was performed four times and the ether flushed out with nitrogen gas, two volumes of cold (−20° C) ethanol was added and stood overnight at −20° C. The mixture was centrifuged at 9,000*g* for 10 min, the pellet was dissolved in 5 mM $MgCl_2$, 0.01 M Tris-HCl (*p*H 7.4). After ethanol precipitation at −20° C, the pellet was again dissolved in 0.01 M Tris-HCl (*p*H 7.4). The supernatant, after centrifugation at 12,000*g* for 20 min was used as the template and was stored at −20° C.

Table 4 Characterisation of the reaction of ^{3}H-UMP incorporation by newborn enzyme with UTP as substrate

	Assay mixture (μg per 0.25 ml)		^{3}H-UMP incorporated pmol)

The reaction mixture had a total volume of 0.25 ml and contained 22 μmol of Tris-HCl (*p*H 7.4), 1.5 μmol of $MgCl_2$, 4.5 nmol of 2-mercaptoethanol, 10 nmol of ^{3}H-UTP (2 × 10^6 c.p.m. per 10 nmol) and 34 μg of newborn brain enzyme and 10μg newborn brain RNA. Incubation was for 20 min.

* 0.2 μmol of ATP, GTP or CTP were added to the mixture to test the effect of ribonucleoside triphosphate. Homopolymers were added instead of RNA.

It is not known whether the enzyme fraction contains only one enzyme mediating both types of synthesis or whether there are two or more specialised enzymes. We hope that this point will be clarified by purification of the enzyme fraction. Physiological roles for two enzyme systems are still obscure. It has been reported that homopolyribonucleotide synthesis in embryonic chick retina is involved in selective gene expression[17], and so we assume that our findings that the enzyme activity which is particularly engaged in homopolymeric RNA synthesis in brain tissue is higher in preparations from newborn than adult rats may have physiological significance.

As it is well known that brain RNA changes according to functional activities[11], we suggest that the enzyme reaction may participate in brain function, although we have no direct evidence of physiological function of this enzyme in the brain at present. We are now investigating whether this reaction exists in other tissues.

We thank Dr T. Ohno and Y. H. Itoh for help and Dr J. A. Coles for help in preparing the manuscript.

No interaction between ultraviolet and X irradiation on chromosome aberrations in cells with trisomy 21

WE have previously shown[1] that ultraviolet irradiation of normal human lymphocytes immediately before or after X irradiation gives an approximately two-fold increase of the frequency of dicentric chromosomes as compared with the yield induced by X rays alone. Ultraviolet light itself induces very few dicentrics. One interpretation of this synergistic reaction might be that lesions induced by X rays are transformed into chromosome breaks by the ultraviolet treatment.

Here we report that no synergistic effect between ultraviolet light and X rays was observed after combined irradiation of blood lymphocytes of individuals with Down's syndrome (trisomy 21). The finding that the chromosome constitution influences the interaction between ultraviolet and X irradiation is of special interest as it has previously been shown that cells with trisomy 21 have a higher sensitivity for chromosome breakage than normal cells after single irradiation with ^{60}Co or X rays[2,3].

Unstimulated lymphocytes resting in the G_0 stage were treated with ultraviolet and X rays in three separate experiments. Peripheral blood from three 47, XY, +21 patients and two 46, XX healthy donors was used immediately after venipuncture. The leukocytes were separated as buffy coats, after which the cells were suspended in a phosphate buffer and irradiated in plastic Petri dishes. The irradiations were made at room temperature and the time interval between the ultraviolet (2537Å, 6.1 erg mm^{-2} s^{-1}) and X-ray (260 kV, 11 mA, HVL 2 mm Cu, 50 rad min^{-1}) exposure in the combined irradiation was less than 30 s. Conventional lymphocyte cultures were prepared and PHA added. The cultures were incubated at 37°C for 50 h (experiments A and B) and 52 h (experiment C), with colchicine added for the last 2 h. Thus, the sampling of cells was made in the first mitotic division, where the aberration yield should not be affected to any appreciable extent by a mitotic delay[4]. After hypotonic treatment and fixation, air dried preparations were made and strained in Giemsa. The slides were screened for consecutive, well-spread metaphases at 10×10 magnification, and the cells were then analysed for dicentric chromosomes (with accompanying fragments) at high-power magnification.

The present results of the induced yields of dicentric chromosomes are given in Table 1. Normal cells exhibit a synergistic effect between ultraviolet light and X rays in agreement with previous data[1]. The 47, +21 cells did not show any significant increase in the dicentric chromosome yield after pre- or post-treatment with ultraviolet as compared with that observed after X-ray exposure alone. The ratio between the number of dicentric chromosomes observed in the combined irradiation to that observed after X irradiation alone is plotted in Fig. 1 for normal cells (including data from ref. 1) and for cells with trisomy 21. The mean values (with standard deviations) of this ratio were $2.07 \pm \frac{0.23}{0.19}$ and $1.15 \pm \frac{0.18}{0.14}$ for normal and trisomy 21 cells, respectively.

In the present experiment the X-ray induced dicentric yield is about 50% higher in cells with trisomy 21 as compared with normal cells. The statistical errors are relatively large, however, and a large significant difference

Table 1 Observed number of dicentrics after single and combined irradiations with ultraviolet (UV) light and X rays.

Experiment	Subject chromosome constitution	Treatment	No. of cells analysed	No. of dicentrics	Dicentrics per cell
A	I : 47, XY, + 21	X rays, 100 rad	100	16	0.16 ± 0.04
		UV, 65 erg mm^{-2} + + X rays, 100 rad	100	20	0.20 ± 0.05
B	II : 47, XY, + 21	UV, 75 erg mm^{-2}	100	2	0.02
		X rays, 125 rad	150	40	0.27 ± 0.05
		UV, 75 erg mm^{-2} + X rays, 125 rad	150	53	0.35 ± 0.06
		X rays, 125 rad + UV, 75 erg mm^{-2}	150	45	0.30 ± 0.05
	III: 46, XX	X rays, 125 rad	150	27	0.18 ± 0.04
		UV, 75 erg mm^{-2} + X rays, 125 rad	150	68	0.45 ± 0.06
C	IV: 47, XY, + 21	X rays, 150 rad	100	40	0.40 ± 0.07
		UV, 55 erg mm^{-2} + X rays, 150 rad	100	41	0.41 ± 0.07
		UV, 75 erg mm^{-2} + X rays, 150 rad	100	42	0.42 ± 0.07
	V: 46, XX	X rays, 150 rad	100	27	0.27 ± 0.06
		UV, 55 erg mm^{-2} + X rays, 150 rad	100	47	0.47 ± 0.07

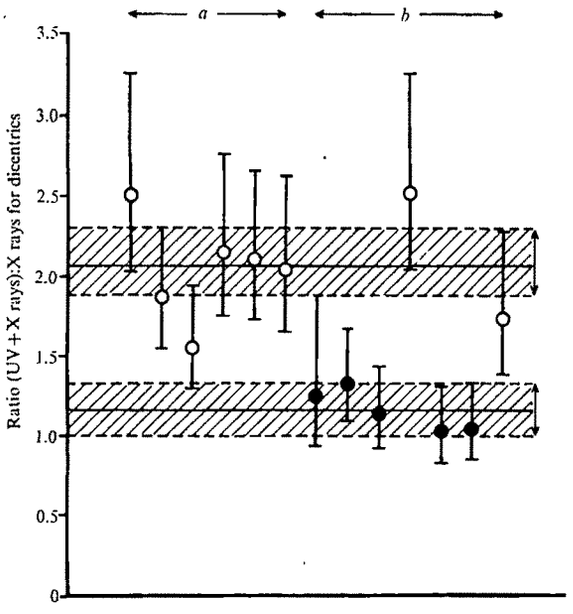

Fig. 1 Ratio between the number of dicentric chromosomes observed in the combined irradiation with that observed after X irradiation alone plotted for male and female normal cells (○) and cells with trisomy 21 (●). *a*, Data from ref. 1; *b*, data from present work.

in radiation sensitivities for the two types of cell is present only in the pooled data of 125 and 150 rad. Sasaki and Tonomura[2] reported an approximately two-fold increase of the radiation (^{60}Co) induced exchange aberration yield in cells with trisomy 21 as compared with normal cells, while the X-ray data by Evans[3] give a yield about 40% higher.

The correlation between the higher yield of X-ray induced chromosome exchange aberrations in cells with trisomy 21 in comparison with controls and the lack of a synergistic effect between ultraviolet and X rays in cells with trisomy 21 cannot be unambiguously explained. The synergistic effect observed in normal cells is, however, (within experimental error) independent of the ultraviolet exposure in the range 50–100 erg mm^{-2}. This correlates with the finding by Evans and Norman[5,6] that the amount of unscheduled DNA synthesis saturates at about 50 erg mm^{-2}. It is not known whether the ultraviolet dose dependence of unscheduled DNA synthesis is different in cells with trisomy 21.

Blood specimens from the individuals with Down's syndrome were provided by Dr J. A. Hedberg, Björnkulla Institution for the Mentally Retarded, Stockholm.

Injection of foreign substances into single cells by cell fusion

A good technique for injecting a given substance into an individual cell would be of value in cell biology. We here report studies on a method for injection of foreign substances into cells with erythrocyte ghosts as 'syringes', making use of the cell fusion activity of HVJ. Mammalian erythrocyte ghosts seem to be the most suitable disposable 'syringes', since they have no cytoplasm or nucleus, so contamination with cellular materials at the time of injection is minimal. Among the many mammalian erythrocytes tested, only human and dog erythrocytes showed high fusion capacity under the routine conditions used for treatment with HVJ (ref. 1).

As a preliminary step, we examined whether haemoglobin was injected into a culture cell during its fusion with an intact human red blood cell (RBC). Cells of a cloned line of FL cells originating from a human amnion cell were used as host cells. About 1 × 10^5 cells suspended in 8 ml of culture medium minimal essential medium (MEM) (with 10% calf serum) were inoculated into a Petri dish, diameter 5 cm, with several round cover glasses, 1 cm in diameter, at the bottom. The dishes were kept for 12 h to allow the cells to settle on the cover glasses. A suspension of 1.5% RBCs was made with balanced salt solution, BSS$^+$ (ref. 2) and the suspension was kept at 4° C until use. After removal of the culture medium, the cover glasses on which the FL cells had been plated were washed with cold BSS$^-$. To coat the surface of FL cells with HVJ, 1.5 ml of ultraviolet-irradiated HVJ (ref. 3), 1,500 haemagglutinating units[4], suspended in cold BSS$^-$ were added and the culture was kept at 4° C. After 20 min free viruses were washed off with cold BSS$^-$. Then, 2 ml of the RBC suspension were poured into the Petri dish and kept at 4° C for 30 min to allow the RBCs to be adsorbed to the surface of HVJ-coated FL cells. Under these conditions, no cell fusion occurred. After completion of the adhesion of RBCs, the BSS was removed carefully and 5 ml of warm BSS$^+$ was poured into the Petri dish. The culture was then incubated at 37° C for various periods, during which cell fusion between FL cells and RBCs was expected to occur accompanied by haemoglobin injection into the FL cells. The incubation periods used were 0, 20, 45, 90 min, 1 and 2 d; for incubation for longer than 20 min ordinary culture medium was used. After each of these periods a cover glass was taken out and washed with PBS (phosphate buffered saline, *p*H 7.2) to remove free RBCs and then stained with benzidine[5] to detect haemoglobin in the FL cells. The percentages of benzidine positive cells after incubation for 0, 20, 45 and 90 min were 0%, 22%, 34% and 36%, respectively. The injected haemoglobin spread rapidly throughout the cytoplasm. The presence of haemoglobin in FL cells was still clearly demonstrable after incubation for 1 or 2 d. It is significant that all the FL cells into which haemoglobin had been injected looked normal and many dividing cells containing haemoglobin were observable in long-term cultures.

The haemoglobin had to be replaced by other substances without destroying the fusion capacity of the RBCs. For this experiment we chose fluorescein isothiocyanate (FITC) because it is easy to detect. Packed RBCs (1 ml) were haemolysed by addition of 5 ml of cold distilled water. The resulting lysate was centrifuged at 11,000*g* for 10 min and the supernatant discarded. Six-fold diluted PBS was added to the pellet to remove haemoglobin and the mixture was centrifuged in the same way and the supernatant discarded; this procedure was repeated three times. Six ml of a solution of 0.05 mg ml^{-1} of FITC in six-fold diluted PBS were then added to the pellet. The mixture was stirred and centrifuged at 11,000*g* for 10 min and the

supernatant discarded; this procedure was repeated twice. The pellet was then treated similarly with the same concentration of FITC in half-strength PBS and centrifuged at 11,000*g* for 10 min. All these procedures were carried out at 4° C. Finally, the pellet was mixed with the same concentration of FITC in 10 ml of full strength PBS and the mixture was incubated at 37° C for 30 min. It was then centrifuged at 7,000*g* for 10 min and the supernatant discarded. The resulting yellow RBCs were washed with PBS by repeating centrifugation at 1,700*g* for 15 min until the supernatant became colourless. The external appearance of the yellow RBC containing FITC was indistinguishable from that of intact ones and the FITC fluoresced intensely. For preservation, the cells were suspended in cold PBS with 4 mM ATP and 0.1 mM $MgCl_2$. It was estimated that each corpuscle contained about 4.4×10^{-3} pg of FITC. No leakage of FITC from the corpuscles was observable during overnight storage.

Cell fusion between FL cells and the yellow RBCs was tested following the procedure described above. In this case, however, on long-term incubation the FL cells died as a result of the cytotoxic effect of the very small quantity of FITC which leaked from the RBCs during reactions with HVJ, so the presence of FITC in FL cells had to be checked after relatively short incubations of 20 min and 60 min. Cover glasses were removed from Petri dishes, washed with PBS, placed on a thin slide with the cells downwards and enclosed in buffered glycerine. Fluorescence was examined in a fluorescent microscope under a dark field and injected FITC in the FL cells was demonstrated. The frequency of injection was less than that of haemoglobin, however, being lower than 1%. Because FITC is highly cytotoxic, considerable numbers of FL cells may have been killed and detached from the surface of the cover glass immediately after the injection started, so the actual rate of FITC injection may in fact have been much higher. This result is encouraging, however, since intracellular injection of FITC was achieved, albeit at low frequency.

There are several possible advantages of this method. First, it is well known that HVJ causes a cell fusion reaction to a greater or lesser extent in almost all cultured cells, so intracellular microinjection into them will be possible. Second, with further improvement of the method it should be possible to control the dose of substance injected into a single cell. Third, it should be emphasised that after injection of haemoglobin FL cells were healthy and continued to divide, so the injection procedure itself is not basically harmful to the cells.

There are also possible difficulties in the method. There are technical limitations to replacing haemoglobin with other substances. During injection of intracellular substances, the RBC membrane is inevitably transplanted into the plasma membrane of the target cell, but it may have no appreciable effect, since during repeated cell divisions molecules of the transplanted RBC membrane will undergo progressive geometric dilution. Moreover, the transplanted RBC membrane may be a good marker to identify cells which have received an injection, because RBC membrane-specific antigens should be detectable by staining labelled antibody[6].

We plan to examine appropriate conditions for fusion of a single cell with a single RBC.

Mechanisms of sensing chemical gradients by polymorphonuclear leukocytes

ALTHOUGH it has been known for nearly 100 yr that polymorphonuclear leukocytes (PMNs) can show oriented locomotion in response to chemical gradients, that is, they display chemotaxis, the way in which these cells detect and respond to chemical gradients is still not understood[1]. These questions are of interest, not only to a study of the inflammatory process, but also to more general problems of oriented cell movements during morphogenesis.

Current studies on bacterial chemotaxis indicate two distinct methods by which an organism can sense a chemical gradient[2,3]. An organism could sense the concentration of a chemotactic substance at one point, move a certain distance and sense it again, comparing this new level with the previous one. This has been termed a 'temporal' mechanism, as the organism compares between two times. In a 'spatial' mechanism the organism compares the concentration of a chemotactic substance at two or more locations on its body at one time. The mechanisms differ in that the temporal mechanism requires only one receptor somewhere on the organism and a simple memory system, whereas the spatial mechanism requires at least two spatially separated receptors on the organism and implies that the organism is capable of sensing the gradient across its own dimensions[2,4]. Analysis of films of horse leukocytes initiating and exhibiting chemotaxis demonstrates that these cells utilise the spatial mechanism. This conclusion is supported by Ramsay's observations of a human PMN responding to a moving chemotactic stimulus[7].

Time lapse films were made of horse blood neutrophilic leukocytes in a thin slide coverslip preparation as they responded to a chemotactic stimulus generated by other leukocytes in contact with a line of aggregated γ globulin that had been previously dried on the slide. The details of the preparation have been described previously[5].

The magnitude of the chemotactic response was quantitated in three ways. First, the number of cells locomoting toward the chemotactic source was compared with that of cells moving away from it. Of the 80 PMNs filmed, 78 moved towards the chemotactic source, that is, into the 180° sector containing the chemotactic source, no cells moved away and two were immobile. Second, the precision of the orientation of cellular locomotion was determined by comparing the orientation of movement of individual cells with the most direct possible path to the chemotactic source. In this analysis the successive positions of 30 cells were traced by projecting frames of the time lapse films onto drawing paper. As the cells tend to move in straight lines for short periods of time, the traced paths could be broken into segments of straight movement (that is movements having less than a 10° change in direction which were separated by relatively abrupt turns of varying magnitude). The tracing of four such cell paths is shown in Fig. 1. From the distribution of straight segments shown in Fig. 2, it was calculated that 65% of segments were oriented within 30°

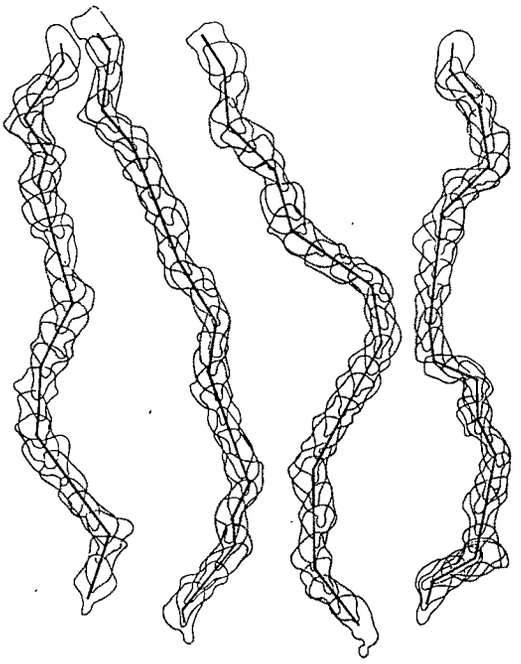

Fig. 1 The tracings of four cell paths is a 16× field immediately adjacent to a line of aggregated γ globulin filmed at 60 frames min^{-1}. The film was projected on paper and at every 30th frame the cell images were drawn. The cells move from the bottom of the figure toward the top; the γ globulin line was parallel to the top edge of the figure. Straight lines were drawn through segments of the tracings which showed less than a 10° change in direction. These lines were then analysed for their orientation relative to a perpendicular to the γ globulin line, their length, and the magnitude and direction of the turns linking the various straight segments.

of the most direct path. Third, the degree of chemotaxis was also evaluated with the chemotropism index of McCutcheon by determining the ratio of the length of the most direct path to the chemotactic source to the path length measured from the film tracings[6]. The chemotropism index ranged from 0.61–0.97 with a mean of 0.85 and s.d.m. of 0.01. The index is higher than those previously published[6–8]. From these observations it can be concluded that PMNs can sense and respond with high accuracy to a chemical gradient. The observed abilities of the PMNs to orient is presumably less than their maximal capability as with a more perfect gradient or a more potent chemotactic substance they could be expected to respond even more accurately.

Studies have shown that bacteria swimming in a gradient of a chemotactic substance have a lower frequency of turning when they are moving up the gradient than when they are moving down[2,3]. This variation in turning behaviour with the orientation of swimming causes the ratio of cells moving up the gradient over those moving down to exceed one. Previous studies on PMNs have suggested that randomly moving cells have a higher frequency of turns and stops than cells exhibiting chemotaxis[3,6]. In my present study the frequency and magnitude of turns were examined with PMNs which were moving with various orientations to a chemotactic source. The distance between turns did not alter as a fuction of the orientation of the locomotion. (coefficient of correlation was -0.169, $N=68$, $P>0.1$). Thus a cell which deviated 40° from the direct path to the source continued in this direction as far as one headed directly towards the source. In the population studied, no cell was moving at an angle more than 100° from the direct path to the source; in situations of less efficient orientation a significant correlation might exist. In this same population, however, a significant correlation was found between the magnitude of a turn and the orientation of that cell immediately before the turn (coefficient of correlation $=0.35$, $N=68$ $P\leqslant 0.01$). The further a cell was oriented from the direct path the greater the magnitude of the next turn tended to be. The correlation, however, was not strong.

Probably an even more important factor in the orientation of moving PMNs than the magnitude of turn is the direction of the turn. Thus 15 out of 16 cases where a cell in the tracings was moving at an angle of 30° or more from the direct path to the chemotactic source, the direction of the next turn by the cell was towards the source; the probability of this bias occurring by chance is less than 0.001.

These behaviour patterns of cells exhibiting chemotaxis are consistent with a spatial mechanism of sensing the gradient. The directional turning response of cells rules out a simple temporal system based on readings at only two points as such a system would not allow the cell to decide in which direction to make its next turn. The data, however, do not eliminate a more complex temporal sensory mechanism which envisions moving cells as having the ability to 'remember' the concentration levels over two preceding intervals as well as the direction of the turn linking the two. This mechanism would give the cell as much information as a spatial mechanism with three or more receptors (knowledge of the concentration at three points in a plane is sufficient to determine the direction and relative steepness of an undirectional gradient in that plane).

To differentiate between spatial and temporal mechanisms I observed the initial orientation of cells placed in a chemotactic gradient. Only a spatial mechanism should allow cells to detect the direction of a gradient while stationary. The direction of initial locomotion of PMNs placed on a slide bearing a streak of aggregated γ globulin was analysed. Filming was begun 3 min after the preparation was made; at this time the PMNs were still rounded and immobile. Gradually the cells began to extend pseudopods, the cells nearest the line of γ globulin first, followed by cells further away. The direction of the initial locomotion was towards the source of the chemotactic agent. In the microscopic field filmed, 18 out of 20 cells which moved either towards or away from the chemotactic source, extended their first pseudopod and made their initial

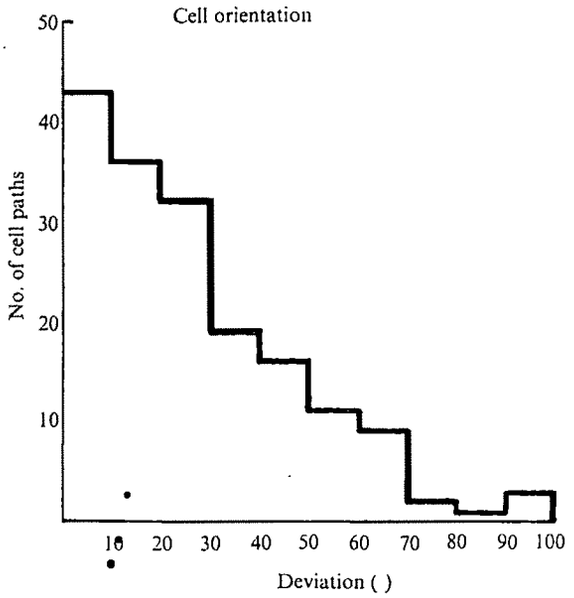

Fig. 2. The number of straight segments of cell paths is plotted against their orientation relative to the perpendicular to the γ globulin line. A total of 172 straight segments taken from the tracings of 30 cell paths were measured.

translocation (of at least ½ their body length) into the 180° sector toward the chemotactic stimulus. This population distribution would occur by chance less than 1 time in 1,000. Thus, the stationary cells are able to sense the gradient across their own dimensions and to respond directionally from the stationary position, an ability characteristic of an organism with a spatial mechanism of detecting gradient (a specialised temporal system where a single receptor is moved over the cells' surface is an alternative, unlikely, possibility).

In response to the chemotactic stimulus the frequency of pseudopod formation increased on the high concentration side of the cell. Before initial migration, the stationary cells did show changes in shape but usually these did not include the formation of structures which could be recognised as pseudopods, either with 16× or 100× microscope objectives. Furthermore, cells greater than 1 cm from the γ globulin line normally remained rounded even after 1.5 h incubation.

How the cell utilises information obtained by the spatial sensory system to selectively form pseudopods is unknown. Possibly there is a time and concentration dependent threshold of stimulation at the membrane which when activated leads to local pseudopod formation and a refractory period inhibiting pseudopod formation on other portions of the cell[10]. Alternatively, the cell could have an internal means of comparing the amount of stimulation of its various sides; for instance local stimulation could affect the distribution of some limiting cofactor required for pseudopod formation. Further studies will be required to distinguish between these and other alternatives.

I would like to thank Michael Abercrombie for many helpful discussions. I am a Fellow of the Leukemia Society of America Inc.

Optimal recovery of lymphocytes and tissue culture cells following rapid cooling

CELLS die if cooled either too rapidly or too slowly during freezing in the presence of dimethylsulphoxide (DMSO)[1-4], but survive at an intermediate optimal cooling rate[5]. We have now obtained improved recovery of lymphocytes, lymphoid cell line cells and Chinese hamster tissue culture cells by interrupting rapid cooling with a timed exposure to a single subzero temperature. This method is simple and here we put forward some theoretical reasons for the improved cell recovery.

Dulbecco's medium containing DMSO (5% v/v) was added to gelatin-separated human peripheral blood lymphocytes immediately before dispensing 0.2 ml aliquots into sterile glass test tubes (10 cm long, 7. mm outer diameter, 5 mm inner diameter). The tubes were immersed either in a constant temperature alcohol bath (± 0.2° C, ref. 6) or in a bath of glycerol solution inside a commercial deep freeze. The bath temperature was measured by a calibrated resistance thermometer[7]. After different times at the chosen subzero temperature, the tubes were plunged into liquid nitrogen. A typical sample reached −25°C in less than a minute from room temperature, the subsequent drop to −196°C took less than 20 s. The samples were thawed in a water bath at 37°C for 20 s. The lymphocytes were diluted in one step with 1.0 ml of serum-gelatin and cultured as previously described[1,5]. Recovery was assessed by uptake of ^{3}H-thymidine (^{3}H-TdR) on the third or fourth day of culture of lymphocytes stimulated with phytohaemagglutinin (PHA).

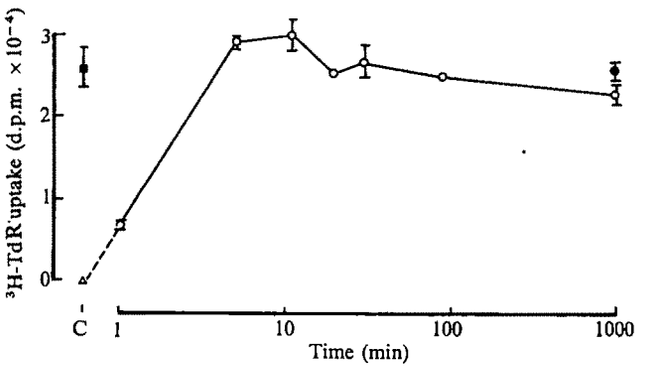

Fig. 1 PHA-stimulated ^{3}H-thymidine uptake (d.p.m.) of unfrozen control lymphocytes without DMSO (■), and thawed cells frozen in DMSO (5% v/v) either directly to −196°C (Δ) or kept at −25.6°C for different times before either thawing (●) or plunging to −196°C before thawing (○).

Figure 1 shows the recovery of cells held at −25.6°C in the deep freeze before immersion in liquid nitrogen. Complete recovery (100%) of the PHA-induced ^{3}H-TdR uptake was obtained with cells held from between 5 min and 18 h at the subzero temperature before cooling rapidly to −196°C. There was no recovery of ^{3}H-TdR incorporation by cells cooled directly to −196°C without exposure at −25.6°C. Using holding temperatures of −22°C, −26°C, −30°C and −40°C the maximum recoveries of PHA-responsive lymphocytes were 18%, 100%, 65% and 40% respectively. Cells held at the sub-optimal temperatures of −22°C and −40°C for 1 to 2 h were damaged on thawing from that temperature; no additional damage was seen when replicate samples were cooled to −196°C before thawing. With DMSO (10% v/v) complete recovery of ^{3}H-TdR uptake in response to PHA was obtained only after 50 min at −26.3°C in the alcohol bath. It was important to cool the sample rapidly to the subzero holding temperature. Even 0.5 ml samples of cells in polypropylene Sterilin tubes showed a slower recovery with time at −25.2°C in the alcohol bath, in comparison with the 0.2 ml samples in the glass test tubes.

Recovery was also observed with two other cell types known to succumb to rapid freezing. Lymphoid cell line cells (Cla 4) showed 100% recovery after 30 min at −26°C before cooling to −196°C. Recovery was assessed by ^{3}H-TdR uptake for 24 h. Chinese hamster lung fibroblast cells (V79-379A) were grown and collected as previously described[8]. Duplicate samples were frozen in the same manner as the lymphocytes in Eagle's minimal essential medium with DMSO (5% v/v). On thawing, the samples were plated for colony assay. Cells frozen directly to −196°C from room temperature showed no colony growth on thawing (Fig. 2). Between 1 min and 10 min at −26.0°C

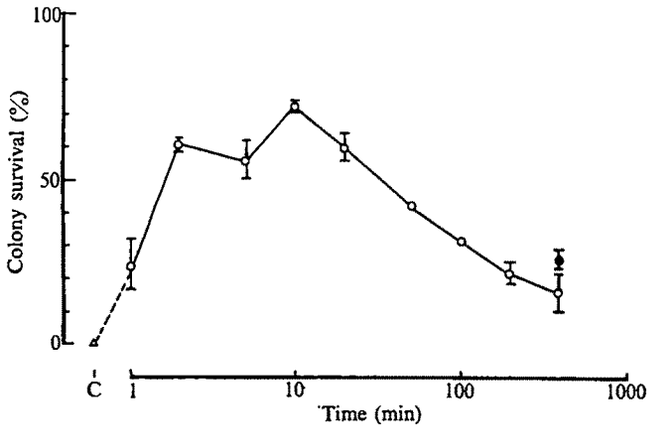

Fig. 2 Colony growth (as % of unfrozen control) of Chinese hamster tissue culture cells thawed after freezing in DMSO (5% v/v) either directly to −196°C (Δ) or kept at −26.0°C for different times before either thawing (●) or plunging to −196°C before thawing (○). The plating efficiency of the unfrozen control was 66.5%.

the survival of tissue culture cells thawed from liquid nitrogen increased to a maximum of 73% at 10 min. With longer times the survival decreased.

These results demonstrate a simple method of obtaining a high survival of different cell types after storage in liquid nitrogen. With human lymphocytes we obtained complete survival of responses to PHA with a low concentration of DMSO (5% v/v). Using conventional optimal cooling rate techniques, this concentration does not allow complete survival[9].

The basis of the present method is the realisation that there is a zone of subzero temperature, exposure to which protects cells against damage due to the subsequent stresses of both rapid cooling to −196°C, and rapid thawing and dilution. This was shown some time ago by Luyet and Keane[10] for bull spermatozoa and by Taylor[11] for chick skin cells. Our results show that the protective properties of different subzero temperatures are affected by physical factors such as the initial concentration of DMSO before freezing. In addition, different cell types respond differently to the same subzero protective environment, thus providing a possible method for their separation.

We propose that this temperature zone conferring protection to cells against subsequent freezing and thawing damage explains the established finding that most cells will survive freezing if cooled slowly (for example at 2°C min^{-1} for lymphocytes in DMSO 5% v/v)[1,5] rather than rapidly. The disadvantage of the conventional optimal cooling rate appears to be two-fold. First, damage may be produced by the initial slow attainment of the best protective temperature (for example the cooling from 0°C to −26°C for lymphocytes in DMSO 5% v/v); second, if slow cooling is continued below the protective zone damage may be caused. The beneficial effects of the two stage cooling rates sometimes used[12,13] can thus be explained. The logical improvement is rapid cooling to the optimal protective temperature, a period at that temperature to confer protection, followed by a rapid cooling to storage temperatures.

We have shown that two separate processes determine the survival of the cells thawed from −196°C; these are damage at the holding temperature and protection against damage on subsequent freezing and thawing.

The mechanism of the protection with time is unknown. It bears one similarity to the thermal shock system[14] where red cells cooled slowly from + 37°C to 0°C in hypertonic sodium chloride are haemolysed less than cells cooled rapidly[15,16]. The rapidly cooled red cells could be protected, however, by increasing the time of exposure to the hypertonic conditions before cooling[16]. The mechanism of protection at the subzero temperature may involve membrane changes induced by the hypertonic conditions, water or solute movements across the cell membrane or the redistribution of ice.

We believe that these results will form the basis for simple improved techniques for cellular preservation.

Are there differences in contact inhibition of movement between normal and malignant cells

STOKER[1] claimed that the malignant cells transformed from BHK cells by polyoma virus showed a lack of contact inhibition of movement unlike their progenitor strain BHK 21 C 13. One of us[2] reported that measurements made of the degree of contact inhibition shown by these two cell types showed that both displayed the same degree of contact inhibition. Measurements were, however, made at one culture age and population density of cells. It is known that contact inhibition of movement of embryonic chick fibroblasts varies with both population density and culture age[3]. Neither Stoker nor Curtis examined the effects of these factors on the contact inhibition of Py or C13 cells. Thus the disagreement between the results of Stoker and one of us is ripe for further investigation. We report here measurements on the contact inhibition of these two cell types at different culture ages and densities.

BHK C13 and Py cells cultured in this department and originally derived from the Department of Virology, University of Glasgow were obtained from stock cultures by trypsinisation. The cells were grown in Eagles +10% calf serum 10% tryptose phosphate medium. Cultures were started with inoculum densities of 6.4×10^5, 3.2×10^5 and 1.5×10^5(C13) 9.0×10^5, 4.5×10^5 and 1.5×10^5(Py) cells per dish (60 mm Polystyrene) in order to obtain different population densities at any one culture age. Cultures were fixed at 20, 24 and 48 h after inoculation. They were stained with Harris's haematoxylin and contact inhibition measured by

Table 1 Variation of mean overlap ratio with culture age and population density

				$F = 13.32$ (d.f.1:40)

* Expressed as cells per counting area (1.8×10^{-8} m^2).
† y is overlap index.

counting the number of overlaps in a known area of measured cell population. Overlap index[4] was used as a measure of contact inhibition.

The results are tabulated in reduced form in Table 1*a* and *b*. The full results were analysed by multiple covariance analysis in Table 1*c*. The planes of the regression equations for C13 and Py cells are significantly different, F=13.32, d.f.1:40 $P<0.5\%$. Comparing the differences in slope of the regression coefficients for culture age (x_1) alone and for population density (x_2) alone respectively we find that both pairs of coefficients are significantly different. (F=10.29 $P<0.5\%$ for x_1, F=36.8, $P<0.5\%$ for x_2).

Thus the response of Py and C13 cells in their overlap indices to culture age and population density differ. Overlap index increases with population density and age in the normal C13 cells, in other words contact inhibition of movement decreases with these changes. But Py cells show the inverse situation. Contact inhibition of Py cells increases with culture age and population density. In consequence it is possible to choose culture ages and population densities such that cultures of both cell types will show the same degree of contact inhibition of movement; presumably this is what happened in earlier work on these cells. But the results also show that Py cells never show a lack of contact inhibition. It will be important to discover whether similar situations exist in other comparisons that have been made in the contact inhibition of normal and malignant cells.

At the moment we can only speculate about the cause of this difference. It is well known that there are surface and other changes in cells as culture age and population density increase[5–7] though the effects of age and density do not seem to have been separated in such work. Possibly one or more of these changes is related to the changes in contact inhibition we have observed. In many of these situations malignant and normal cells differ in their reaction to culture age and population density.

New fungal viruses capable of reproducing in bacteria

MANY authors have reported the isolation from fungi of virus particles containing double-stranded RNA[1–5]. It has also been found that extracts of *Penicillium brevi compactum*, *P. chrysogenum* and *P. stoloniferum* can lyse certain bacteria. Fractionation of such extracts and also disruption of spores have revealed the presence of several types of virus particles differing in their biochemical and biological properties. This series of viruses was called PBV, with reference to the host (P) and to their ability to lyse bacteria (B).

Table 1 shows the results of titration of an extract of the mycelium, supernatant and spores of the three species of fungi mentioned above with the cells of *Escherichia coli* C and *E. coli* SK. The infectivity towards bacteria increases as the mycelium grows. No free virus was detected in the supernatant of *P. brevi compactum* after the mycelium was removed, whereas with the other two fungi virus was found in both the mycelium and the culture medium. Viruses which could multiply in bacteria were also found in preparations of the disrupted spores, as well as in preparations of disrupted mycelium not subjected to ammonium sulphate fractionation. In the latter case, the titre of virus in suspension was 1.5–2.0 log lower.

When the fungi were grown in the presence of 250 μg ml^{-1} neomycin, which has a wide spectrum of antibacterial action, the quantity of PBV determined by titration with bacteria does not change as compared with the control without antibiotic. No bacteria were detected at any time in the fungal culture. The results were the same with different strains of *P. brevi compactum* (13 strains have been studied). Figure 1 shows the results of equilibrium centrifugation of mycelial extracts in a Cs_2SO_4 density gradient. The gradient shows several peaks of infectivity to bacteria. The positions of these peaks are different for *P. brevi compactum* and *P. stoloniferum*.

A further investigation has shown that in *P. brevi compactum* extracts there are two types of viruses infective to bacteria (PBV1 and PBV2) in the regions of density 1.38 and 1.40 g cm^{-3}. In the 1.32 g cm^{-3} region[6], a double-stranded RNA-containing mycovirus is present, which seems to be somewhat smaller in comparison with the mycovirus of

P. brevi compactum described by Wood *et al.*[7] (300 Å in diameter as measured by us compared with 400 Å indicated by Wood). In the 1.42 g cm^{-3} region there is a third virus, PBV3. The 'light' zones of the density gradient (1.25–1.32 g cm^{-3}) also show some infectivity with respect to bacteria.

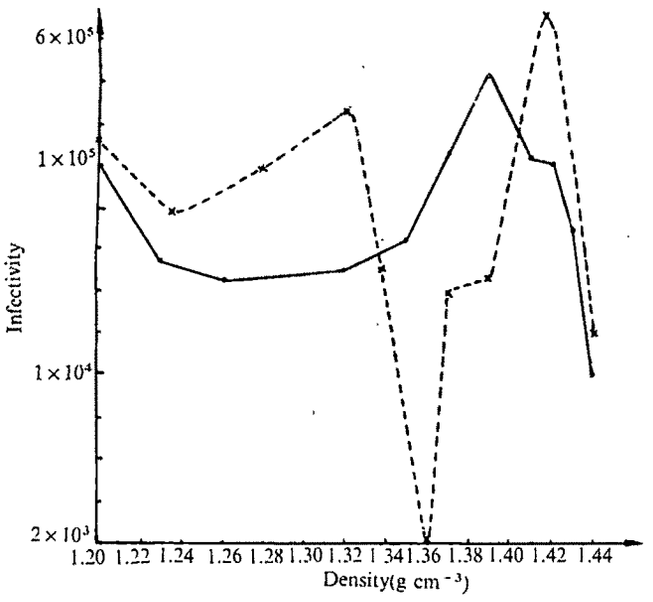

Fig. 1 Equilibrium centrifugation of the extract of *P. brevi compactum* and *P. stoloniferum* mycelium in Cs_2SO_4 density gradient. Preparation and concentration of the extract with ammonium sulphate were carried out as indicated in the legend to Table 1 (the extract of *P. brevi compactum* mycelium was concentrated 10-fold, the extract of *P. stoloniferum*, 1,000-fold). The extracts were layered on the preformed Cs_2SO_4 gradient (1.22–1.44 g cm^{-3}) and centrifuged for 16 h in a 3×5 ml rotor at 35,000 r.p.m. in a Superspeed 50 centrifuge. In the gradient fraction (0.27 ml) infection titre was determined with *E.coli* SK cells by Gracia[8] without dialysis. Under the dilution used the Cs_2SO_4 concentration was low and did not influence the results of titration. ———, *P. stoloniferum* extract; – – –, *P. brevi compactum* extract.

Pure lines of PBV1, PBV2 and PBV3 were obtained (some of their properties are presented in Table 2).

PBV1 and PBV3 comprise icosahedral particles with long noncontractile tails, resembling λ phage; PBV2 is an icosahedral particle with a short tail, resembling T5 phage[6]. The nucleic acid of viruses PBV1 and PBV2, judging by the colour reaction, T_m and buoyant density is a typical double-stranded DNA. PBV1 has an extremely wide spectrum of antibacterial action; it can lyse *E. coli* B, *E. coli* C, *E. coli* K12 and *E. coli* SK; PBV2 lyses only *E. coli* SK. PBV3 was infective towards *E. coli* C, *E. coli* B and *E. coli* SK, and has an abnormally high buoyant density in Cs_2SO_4.

Many facts lead us to believe that titration of mycelium extracts on bacteria did reveal the fungal viruses and not some fungal substances which could induce lysogenic prophages in the bacterial cells. Some of these data are summarised in Table 3. First, definite mycelium fractions after equilibrium centrifugation gave several types of colonies on the same bacteria, differing in size and morphology. From these colonies pure viral lines were isolated which after many passages through bacteria had the same buoyant density and gave the same type of colonies as respective viruses in the fungal extracts. This is evident particularly in the case of PBV3 which has an abnormal buoyant density in Cs_2SO_4.

Second, antisera against three isolated and purified PB viruses grown in bacteria neutralise the infectivity of the fungal fraction towards bacteria. The fraction of density 1.42 g cm^{-3} contains chiefly PBV3 (Table 3) which gives large clear colonies with a halo on *E. coli* SK. PBV1 and PBV2 give large clear colonies without haloes and large turbid colonies respectively and represent an admixture of PBV3 as a result of overlapping zones occupied by these viruses. The same is true for the fractions of density 1.40 and 1.38 g cm^{-3}. Neutralisation experiments with other fractions (1.32 and 1.38 g cm^{-3}) are now under way.

Thus, we conclude that fungal extracts contain virus particles infective towards bacteria. Otherwise *E. coli* C or *E. coli* SK cells would have to contain at least four different prophages which can be induced by fungal substances and at the same time do not restrict the subsequent infection by

Table 1 Titration of Mycelium preparations on *E. coli C* and *E. coli* SK

Fungus species	Time of growth (h)	Infectivity per g biomass *E. coli* C	Infectivity per g biomass *E. coli* SK	Infectivity titre in culture medium *E. coli* C	Infectivity titre in culture medium *E. coli* SK
P. brevi compactum N 192	6	1 × 10^2	3 × 10^2	0	0
	17	8.5 × 10^2	2.6 × 10^3	0	0
	24	1.2 × 10^3	4 × 10^3	0	0

	96	2 × 10^6	9 × 10^6	0	0
	Intact spores	0	0	0	0
	Disrupted spores	1 × 10^3	5 × 10^3	0	0
P. stoloniferum 1458	72	2 × 10^3	—	9 × 10^2	—
P. chrysogenum 194	48	9 × 10^2	—	7 × 10^3	—

The sterile growth conditions of the fungus have been described previously[6]. Twice each day the fungus was seeded to detect bacterial flora. The mycelium was separated from the culture medium by filtering through paper filters and then disintegrated either by grinding with quartz powder or by ultrasonic treatment. Many PB viruses are extremely sensitive to temperature, so it must be kept as low as possible during treatment (0.4° C). The disrupted mycelium was extracted with 0.1 M NaCl in 0.05 M phosphate buffer *p*H 7; the virus was then either concentrated by precipitating with 30% ammonium sulphate or directly titrated on bacteria, using the method of Gracia [8]. The spores were treated in a similar way. All the data in the table refer to the culture medium and mycelium extracted per g crude mycelium.

Table 2 Some characteristics of viruses of the PBV series (from *P. brevi compactum*) and their DNAs

Virus species	Buoyant density in Cs_2SO_4 g cm^{-3}	Buoyant density in CsCl g cm^{-3}	Size of head Å*	T_m of DNA 1 SSC	T_m of DNA 0.1 SSC	Buoyant density in CsCl	Buoyant density in Cs_2SO_4
PBV1	1.38	1.49	425 ± 25	88.5°C	72.8°C	1.7078	1.42
PBV2	1.40	1.48	525 ± 25	87°C	72°C	1.7035	1.42
PBV3	1.42	1.51	—	—	—	—	—

The PB viruses were grown according to the standard procedure[8] in a synthetic medium to which broth was added and were then purified by chromatography on DEAE-cellulose, differential centrifugation and equilibrium centrifugation in a Cs_2SO_4 density gradient. DNA was isolated by the phenol method. The DNA preparations were dissolved in 1 SSC. Standard procedures were used for melting of DNA and for reactions with orcine and diphenylamine. The buoyant density of DNA was determined in an analytical centrifuge with known markers (DNA from phage Sd or T5).

*The sizes of the particles are those reported in our preliminary communication[6].

Table 3 Comparison of some properties of PBV originating from fungi and bacteria

Source of Virus*	Buoyant density in Cs_2SO_4 (g cm^{-3})	Colonies on bacteria Type	Diameter (mm)

Extract of *P. chrysogenum*	—	Turbid	1.0–1.3

*Fungal extracts were obtained and centrifugated in Cs_2SO_4 gradient, as indicated in the legend to Fig. 1. The fractions with indicated buoyant density were titrated on *E. coli* SK. The pure lines of PB viruses were grown on *E.coli* C (PBV1, PBV3) or *E. coli* SK (PBV2) purified as described in Table 2 and titrated under the same conditions as fungal extracts (see Table 1 and Fig. 1).

† The antisera against PB viruses were obtained by usual method of immunisation of rabbits with purified PBV preparations (titre 5×10^{10} plaques ml^{-1}) [10]. The results indicated in the table were obtained with antiserum dilution 1:10, which provided the 100% neutralisation, antisera diluted 1:100 neutralised the infectivity in fungal extracts due to PBV2 (turbid colonies) and PBV1 + PBV3 (clear colonies) for 88% and 90% respectively. Normal rabbit antisera did not influence the PBV infectivity in fungal extracts.

‡ The predominant type of colonies.

infective virus originated from this prophage.

Like the double-stranded RNA mycoviruses, the viruses of the PBV series may be isolated only from the cultures of *P. brevi compactum*, and *P. stoloniferum* with modified morphology and from the strains of *P. chrysogenum*, which produce penicillin. The 'healthy' cultures of these fungi or cultures not producing the antibiotic produce neither mycoviruses nor PB viruses. Attempts to infect 'healthy' cultures with PBVs have so far failed.

In summary, mycelium of *P. brevi compactum*, *P. chrysogenum* and *P. stoloniferum* produces, in addition to known mycoviruses, DNA-containing viruses capable of reproducing in bacteria. The relationship of these viruses to the host fungus is still obscure; it is possible that PBVs have a temperate lysogenic relationship with the fungus.

Estimation of the size of a T-cell-induced lytic lesion

The specific cytolytic activity exhibited *in vitro* by thymus-derived (T) lymphocyte populations from immune animals (see review in ref. 1), is germane to allograft rejection[2,3] and to pathways by which neoplastic tissue can be destroyed *in vivo*[4,5]. The mechanism involved, however, remains controversial (for one viewpoint see ref. 6) and the nature of the lytic lesion is unknown.

T-cell-mediated lysis seems to be unrelated to the complement system, for not only can lysis take place in the absence of serum, but added complement augments neither the rate nor the extent of lysis[7]. Perhaps more pertinently, antisera against complement components C_2, C_3 and C_5 do not interfere with the lytic process[8].

Time-lapse cinematography of lymphocyte-mediated cytolysis revealed lysis as a ballooning phenomenon, in which the antigen-bearing (target) cell became swollen and ruptured after contact with a lymphocyte[9]. Studies from this laboratory on the efflux of material of different molecular sizes from injured target cells have established that the T-cell-induced lytic lesion is progressive[10]. Low molecular weight markers (ATP, ^{86}Rb) were shown to efflux from the damaged target cell before macromolecules (^{51}Cr-protein, ^{3}H-DNA) could pass through the cell membrane. These findings suggest that the original dimensions of the lytic lesion are smaller than the effective diffusion radius of the ^{51}Cr-protein complexes, and are incompatible with 'big-bang' concepts of lymphocyte-induced target cell lysis.

The preferential early efflux of low molecular weight material from target cells suggested that the eventual rupture of the membrane, and the swelling of the target cell observed morphologically, were due to colloid osmotic swelling. This is supported by the findings reported here, for by means of techniques[11,12] used earlier to characterise complement lesions, it was found that when cultures of lymphocytes and target cells were maintained in a solution of high molecular weight (>40,000) dextran, ^{51}Cr-protein release from the target cells could be inhibited while ^{86}Rb efflux continued. Using a series of dextrans of varying molecular size, it was inferred that the initial T-cell-induced lytic lesion in a mastocytoma target cell is of the order of 35–45 Å in radius.

The assay system used, the lysis of DBA/2 mastocytoma cells by spleen cells from alloimmunised C57BL/6 mice, has been described in detail (see legend to Fig. 1)[13,14]. The same system was used to measure specific ^{51}Cr and ^{86}Rb efflux[10]. During the assay times used, specific release of both labels was linear after a lag of 10-15 min for ^{86}Rb and approximately 45 min for ^{51}Cr. The assays were of comparable sensitivity, in that the minimal number of lymphocytes required to cause significant release of label was equal[10]. Typical values for isotope release from 10^5 target cells with 10^7 spleen cells is shown in Table 1.

We have shown[10] that target cell damage after addition of lymphocytes occurs within 15 min, and is characterised by efflux of low molecular weight material. Macromolecules are only released later (> 45 min). If the efflux of high molecular weight material results from osmoregulatory damage, caused by water influx through the initial lesions, then maintaining

Table 1 Release of ^{51}Cr and ^{86}Rb from DBA/2 mastocytoma cells in the presence of immune C57B/6 spleen cells

Time after target cell addition (h)	% ^{51}Cr release		% specific cytolysis	^{86}Rb release			
	Immune	Normal		Time (min)	Normal (c.p.m.)	Immune (c.p.m.)	Specific ^{86}Rb release (△c.p.m.)
1	9.2±1.8	3.6±0.4	5.6	15	541±17	625±20	84
2	22.9±4.0	4.1±0.2	18.8	30	935±22	1,360±18	425
3	40.4±3.7	5.2±0.3	35.2	45	1,294±8	2,124±75	830
4	56.3±5.2	6.5±0.5	49.8	60	1,669±13	2,871±12	1,202

C57BL/6 spleen cells from unimmunised (normal) animals or from mice immunised 10 d previously with 10^7 DBA/2 mastocytoma cells intraperitoneally were incubated with 10^5 ^{51}Cr DBA/2 mastocytoma cells for periods up to 4 h (or with 10^5 ^{86}Rb target cells for periods up to 1h). For the ^{51}Cr release percentage isotope release was calculated relative to the total number of cell-associated counts added to the system. Percentage specific cytolysis merely as the arithmetic difference between release in the presence of immune cells and that with normal cells. Values given are means ± s.d. of quadruplicate assays in one experiment. For the ^{86}Rb assay, because of high turnover of ^{86}Rb in lytic assays and the variability in reporting specific cytolysis from various laboratories (contrast for example the calculation above with that reported in ref. 13), it is considered preferable here to report raw data. The total cell-associated counts at time zero were 4,646±420 c.p.m., the total supernatant counts in the presence of normal and immune lymphocytes is given as c.p.m. ±s.d. of quadruplicate assays. The difference between the mean values was taken as specific ^{86}Rb release. Percentage inhibition of cytolysis in this system was calculated relative to this value.

the target cells in solutions of high molecular weight (non-penetrating) molecules should prevent the progression of the lesion, and prevent macromolecular efflux[11,12].

Using dextrans of various molecular weights, we established that solutions inhibiting cytolysis (^{51}Cr release) were of high intrinsic viscosity. It was considered important, therefore, to establish that inhibition of ^{51}Cr release was due to prevention of macromolecular release from cells bearing a lytic lesion, rather than to inhibition of lymphocyte-target cell interactions by solutions of high viscosity[9,15]. We argued that if inhibition of both ^{86}Rb and ^{51}Cr release was observed, this represented an inhibition of lymphocyte–target cell interaction. If, on the other hand, ^{86}Rb efflux was demonstrable when ^{51}Cr was not, this was regarded as inhibition of the progression of the lesion. Such arguments depend on the following suppositions: (i) that ^{86}Rb and ^{51}Cr are released from injured cells by basically the same mechanism; and (ii) that ^{86}Rb and ^{51}Cr are located either in the same intracellular pool, or that they have equal access to holes in the cell wall.

It follows that inhibitors of cell interactions should affect ^{86}Rb and ^{51}Cr release comparably. The effect of cytochalasin B, an inhibitor of cytolysis[16-19], was thus assayed. Cytochalasin B (0.4-6 μg ml^{-1}) similarly inhibited ^{86}Rb efflux and ^{51}Cr release (Table 2). Additionally, we observed[10] that an inhibitor of the potassium pump (ouabain) affected neither ^{86}Rb nor ^{51}Cr release. These findings are both consistent with the suppositions made above.

Parallel inhibition of ^{86}Rb and ^{51}Cr release was shown when lymphocyte–target cell interactions were made in a dextran solution of mean molecular weight 9,300 (Pharmacia size T10). At concentrations of 20 mM, complete inhibition of specific ^{86}Rb and ^{51}Cr release was found. Decreasing dextran concentrations resulted in a dose-dependent and parallel inhibition of specific ^{86}Rb and ^{51}Cr release (Fig. 1*a*).

Dextrans of mean molecular weight 70,000 (Pharmacia T70) and 231,000 (Pharmacia T250) inhibited specific ^{51}Cr release significantly more than they did ^{86}Rb flux (Figs. 1*b* and *c*). For example, in 0.5 mM, 70,000 molecular weight dextran, specific ^{86}Rb release was suppressed only 6.1% (range 4.2–8.1), whereas ^{51}Cr release was inhibited 38.0% (range 35.0–43.2). Similarly, in 0.1 mM, 231,000 molecular weight dextran, ^{86}Rb release was inhibited 6.5% (range 4.3–9.5) whereas

Table 2 Inhibition of specific ^{86}Rb and ^{51}Cr efflux in the presence of cytochalasin B

Concentration cytochalasin B (μg ml^{-1})	% Inhibition specific cytolysis	
	^{51}Cr	^{86}Rb
0.375	10.0	14.2
0.75	35.2	39.8
1.5	52.0	47.6
3	85.1	79.2
6	97.2	93.4

10^7 immune C57BL/6 lymphocytes (10 d after 10^7 DBA/2 mastocytoma cells intraperitoneally) were incubated with 10^5 ^{51}Cr DBA/2 mastocytoma cells for 4 h at 37°C (or with 10^5 ^{86}Rb target cells for 60 min) in the presence of cytochalasin B. The percentage inhibition of specific cytolysis was calculated relative to control tubes without inhibitor. Data represents mean values of two experiments in each of which the assays were performed in duplicate. Replicate essays in each experiment varied <5%; values from one experiment to the other varied approximately 10%. Cytochalasin B had no effect on the release of either isotope in control cultures.

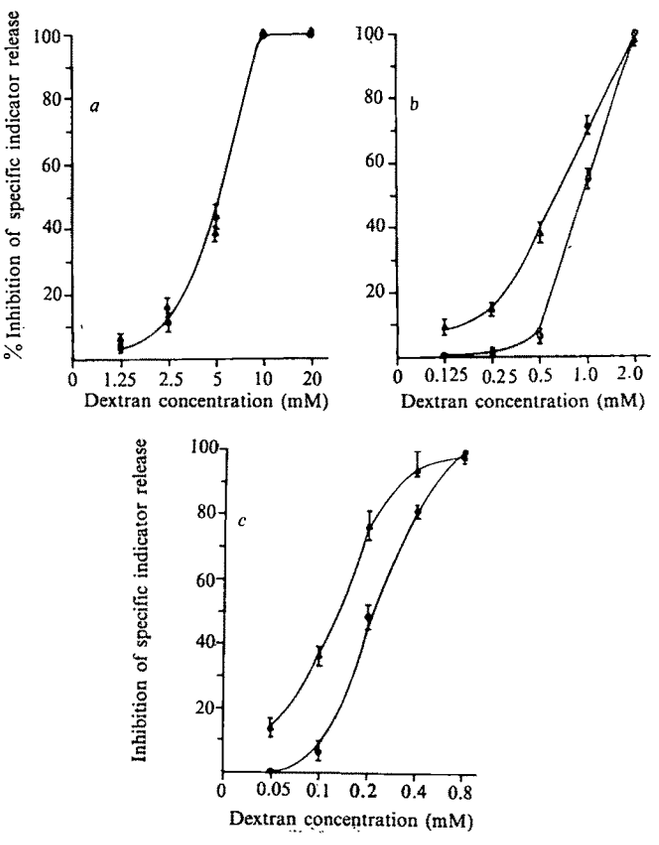

Fig. 1 C57BL/6 spleen cells (10^7) derived from mice immunised 10 d earlier with 10^7 DBA/2 mastocytoma cells intraperitoneally, were incubated with 10^5 mastocytoma cells labelled either with ^{51}Cr(▲) or with ^{86}Rb (●). The cells were mixed in Eagle's minimal essential medium containing 10% foetal calf serum and varying concentrations of dextran. Cytolysis was evaluated 1 h (for ^{86}Rb assays) or 4 h (for ^{51}Cr assays) later. Specific cytolysis was calculated after subtraction of isotope release from control cultures containing 10^7 normal C57B/6 spleen cells in the same concentrations of dextran. Inhibition of specific cytolysis was calculated relative to cultures containing no dextran. The values given are means and range of quadruplicate cultures. Molecular weight: (*a*) 9,300; (*b*) 70,000; (*c*) 231,000.

Table 3 Addition of cytochalasin B or dextran solutions to cytolytic reactions: effect on subsequent ^{51}Cr release

Reacting cells	Inhibitor added after 1 h of incubation†	% Specific ^{51}Cr release in the 2 h following inhibitor addition Expt 1	Expt 2	Expt 3

10^5 ^{51}Cr DBA/2 mastocytoma cells	BSA	—	3.1	—

* Percentage specific lysis at time of inhibitor addition.
† Inhibitors were added to give a final concentration known to be sufficient to totally inhibit specific ^{51}Cr release if present at time of lymphocyte addition to target cells. These final concentrations were: cytochalasin B, 6 μg ml^{-1}; dextran 9,300, 20 mM; dextran 70,000, 2 mM; dextran 231,000, 0.8 mM; BSA, 25 g%. Values given are means of triplicate assays. Replicates in all cases varied < 10%.
Neither dextran nor cytochalasin B solutions affected spontaneous ^{51}Cr release in parallel cultures containing normal lymphocytes.

^{51}Cr release was inhibited 36.2% (range 33.0–39.1). These findings suggest that the high molecular weight dextrans prevent hole enlargement.

We have previously shown that when cytochalasin B is added to a lytic reaction in progress, ^{51}Cr release continues for a period of approximately 1 h before complete inhibition is demonstrable[17]. It seems reasonable to assume that such release is derived from target cells which bore holes before addition of inhibitor, but that such lesions were not initially large enough to accommodate macromolecular passage. It follows that hole enlargement continued in the presence of cytochalasin B and that inhibition was due to prevention of new lymphocyte–target cell interactions[18].

When low (9,300) molecular weight dextran was added to a lytic reaction already in progress, ^{51}Cr release continued in a manner comparable with that found with cytochalasin B (Table 3). In contrast, addition of 70,000 and 231,000 molecular weight dextrans completely inhibited subsequent ^{51}Cr release. Presumably only those molecules which are too large to penetrate the initial hole can afford osmotic protection against water influx (and the subsequent ^{51}Cr efflux).

Dextran solutions of 40,000 molecular weight also gave protection against ^{51}Cr macromolecular efflux, although less than that obtained with 70,000 molecular weight material. Minimal inhibition of ^{51}Cr release was also obtained by addition of 25 g % bovine serum albumin to an ongoing lytic reaction (for example, experiment 2, Table 3).

The single most important criterion dictating molecular passage across a semipermeable membrane seems to be the molecule's effective diffusion radius (R_{ES}) calculated from the Stokes-Einstein equation[20]. From values in the literature[21] for the molecules used in this study, it would seem that dextran molecular weight 40,000 ($R_{ES} \sim 45$Å) and bovine serum albumin of molecular weight 68,000 (R_{ES} 35.5Å), by affording minimal significant inhibition of ^{51}Cr-protein release from cells bearing a Rb hole, represent the approximate initial dimensions of the T-cell-induced lytic lesion.

These findings show a striking similarity to the nature of the antibody induced complement lesion in erythrocytes[12] and in Krebs ascites tumour cells[11,22]. In these cases too, macromolecular passage across a damaged (K permeable) cell membrane, could be prevented by maintaining the cells in non-penetrating protein[22] or dextran solutions[12]. For reasons advanced earlier, there is good reason to suppose that the complement system is not involved in the T-cell-mediated lytic lesion[7,8]. The nature of the effector molecule remains, however, in doubt.

Currently, it seems reasonable to suppose that the initial lytic lesion in the target cell membrane is inserted during the contact between effector T lymphocyte and its homologous target cell. After this initial lesion, the continued presence of the lymphocyte is unnecessary[23], and the demise of the target cell results from its own inability to handle the augmented influx of water into its cytoplasm.

I thank Kirk Ziegler for technical assistance and Dr Marshall Plaut for valuable discussions. This work was supported by grants from the National Institute of Allergy and Infectious Diseases and the US National Science Foundation. I am a recipient of a research career development award from the NIAID.

Note added in proof: Seeman has recently claimed[24] that the approaches used here to estimate lesion size are invalid. He reports that the efflux of haemoglobin (Hb) from hypotonically lysed cells is suppressed by the presence of extracellular macromolecules, even when the size of the membrane lesion is much greater than the effective diffusion radius of the extracellular molecules. He argues that the macromolecules act simply by reducing the diffusion rate of Hb, a suppression which, he asserts, is dependent on the weight-concentration, and not the molecular weight, of the extracellular macromolecule. The latter assertion makes it unlikely that this is an adequate explanation of the phenomenon described here for dextrans of molecular weight 9,000 and 70,000, used at the same weight concentrations, have very different effects on ^{51}Cr-protein release (Fig. 1).

Immunosuppression detected in pregnant mice by rosette inhibition test

ATTENTION has recently been drawn to the immunological mechanisms concerned in the nonrecognition of the antigenic status of the foetus during uterine life. Several workers[1–3] have demonstrated that lymphocyte transformation is suppressed during pregnancy. As the rosette inhibition test[4] has been used to show that the lymphocyte activity *in vivo* is modified by immunosuppressive therapy following trasnplantation[5], it suggests that this technique could also be used to investigate possible immunosuppression during pregnancy.

The rosette inhibition titre (RIT) was estimated as described previously[6]. Antilymphocytic serum (ALS) was produced against mouse spleen cells, and was tested for its effect on rosette formation between mouse spleen cells and human red blood cells (HRBC), (H.M., V.H., and G.J.A.C., unpublished). The HRBC were collected fresh each day from the same donor. The ALS was diluted to 1×10^6 and then serially diluted and tested in the range 1×10^6 to $32{,}768\times10^6$. The spleen cells used were from Quackenbush mice aged between 8 and 12 weeks. The RIT was recorded as the highest dilution of ALS at which the number of rosettes formed was 75% or less of the control (Hank's solution without ALS). The RIT of the ALS produced in this series showed significant correlation with the skin graft survival time.

The results of the RIT performed in two mice, a nonpregnant and a pregnant female respectively, are illustrated in Fig. 1, in which the rosette formation as a percentage of the control (without ALS) is plotted against the dilution of ALS. There was a marked difference in RIT, that in the nonpregnant female being 16×10^6 and in the pregnant female $8{,}192\times10^6$. The RIT of ten pregnant females and the normal group of five males and six non pregnant females is illustrated in Fig. 2. The logarithmic mean of RIT $\times10^{-6}$ (to base 2) in the normal group was 3.2 (s.e., 0.42). The RIT of the pregnant group ranged from 32×10^6 to $8{,}192\times10^6$ (log mean 10.2 s.e., 1.05). There was no significant difference between the mean of the titres of the group containing five males and the group containing six nonpregnant females. There was a significant difference between the mean of the titres of the nonpregnant group (five males plus six females) and the pregnant group (ten females) $P< 0.001$. The mean number of spontaneous rosettes formed in the control with spleen cells from five male mice and six non pregnant female mice was 31.2 (s.e., 2.2) rosettes per 1,500 spleen cells, and the mean number in the control with spleen cells from ten pregnant females was 33.9 (s.e., 2.7) rosettes per 1,500 spleen cells. There is no significant difference between the number of rosettes formed in these two groups.

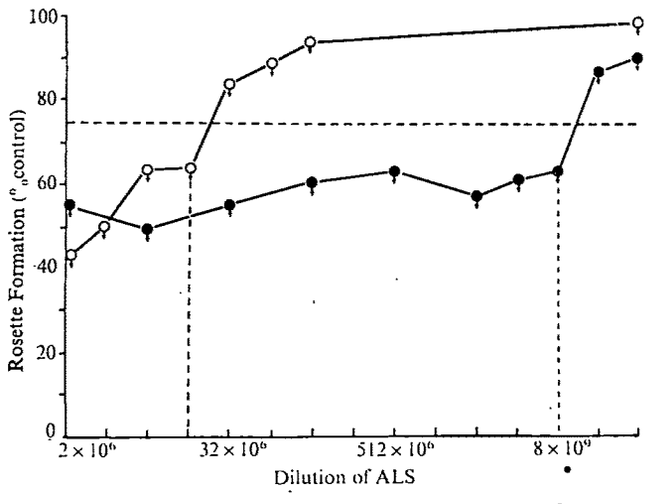

Fig. 1 Rosette formation (as % of the control) with lymphocytes from a pregnant (♀) and a nonpregnant (♀) mouse plotted against ALS dilution, illustrating the high RIT during pregnancy.

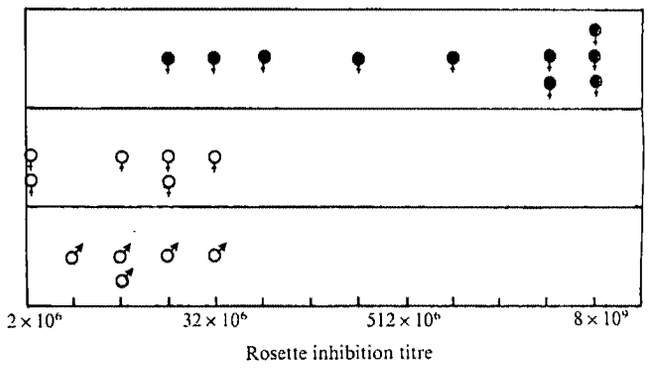

Fig. 2 RIT in male (♂), nonpregnant female (♀), and pregnant female mice (♀), showing rise in RIT in some pregnant females.

To investigate this wide range of RIT in pregnant mice and to follow an apparent change in relation to the stage of pregnancy, mice were killed at different stages after mating and the stage of pregnancy recorded as the crown–rump length of the foetus. A plot of RIT of pregnant mice against crown–rump length of foetus (Fig. 3) indicates

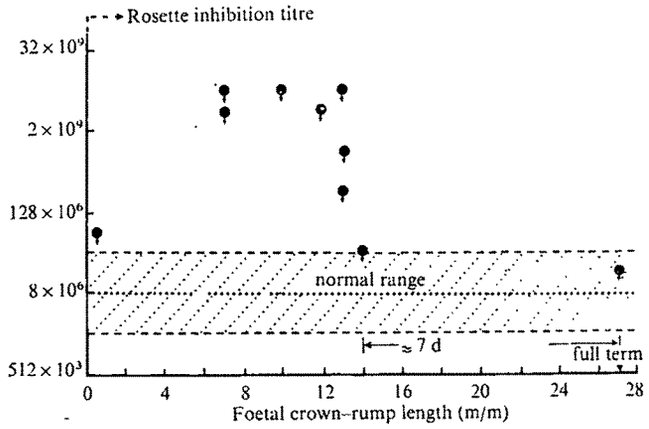

Fig. 3 RIT plotted against stage of pregnancy as measured by crown–rump length, showing a rise in RIT during pregnancy and a fall to normal before delivery.

that the RIT starts to rise early in pregnancy, and then drops to within the normal range approximately 7 d before delivery. The RIT of a mouse tested at full term lay within the normal range.

Our findings support the work of others[1–3] that the immunological competence of material lymphocytes is modified during pregnancy. They found that the phytohaemagglutinin - induced transformation was reduced. Finn *et al.* raised the question whether this was due to a central suppression of the T cells in pregnancy or to fewer T cells present to be stimulated. Our findings support the first of these two hypotheses. If there were fewer T cells to be stimulated then the number of spontaneous rosettes formed in the pregnant group would be less than the number formed in the nonpregnant group. We have found that this is not so, that there was no significant difference between the means of the results obtained from each group.

Contractor *et al.*[3] have concluded from their investigations that HCS and HCG, produced by the placenta, are either binding or competing for the site of PHA stimulation. From our investigations, it seems likely that a similar reaction is occurring. The number of spontaneous rosette-forming cells in pregnancy is not decreased but the number of combining sites on these cells, available for the immunosuppressive activity of the ALS, is decreased. This is shown by the rosette forming activity of these cells being inhibited by much higher dilutions of ALS than those cells from nonpregnant animals. This indicates that the blocking of binding sites on the lymphocyte *in vivo* impairs its immunological competence. We have shown that the RIT begins to return to within normal limits at the beginning of the third week of pregnancy and this lends support to the theory of Contractor *et al.*, that immunorejection may play a part in stimulating parturition.

Stabilisation of interferons by defensive reversible denaturation

THE stabilities of interferons vary widely, depending on their source and degree of contamination. Even relatively stable interferons seem to become labile as various degrees of purity are attained[1]. In the absence of a more suitable means of stabilisation, some investigators rely on addition of extraneous protein to stabilise interferons during purification[2], thus, a method for stabilising interferons would have considerable value.

The commonly encountered inactivations of interferons (deterioration on storage, repeated freezing and thawing, surface inactivation by shaking or frothing, or exposure to heat) occur under conditions where alterations of primary structurrs of protein are not likely; therefore, such inactivations probably result from denaturations involving only disruptions in secondary and tertiary structures. Theoretically such denaturations should be reversible.

Denatured proteins are more likely to return to native conformations if their amino acid sequence is in a linear random coil[3], that is, a primary structure in which all noncovalent bonds and all cross links (disulphide bonds) have been broken. Since some interferons have been reported to contain disulphide bonds[1,4], attainment of a linear polypeptide should require reduction of such groups. As with some interferons, unfolding of the native protein is required to make cross linkages accessible to attack, an agent to disrupt noncovalent bonds would be required. Presumably, interferon polypeptides maintained in

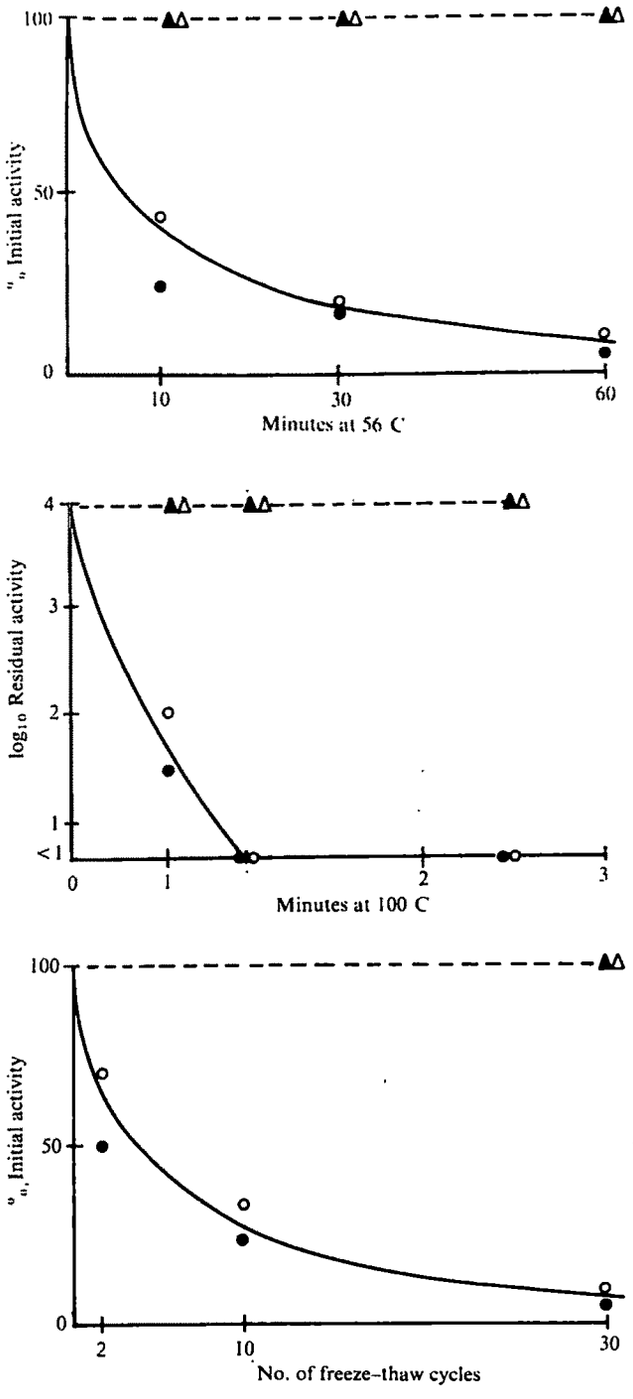

Fig. 1 Stabilisation of interferons by 'defensive' reversible denaturation. Interferons were subjected to the indicated treatment in their native state (○, ●) or in the 'defensively' denatured state (△, ▲). ●, ▲, Mouse interferon; ○, △, human interferon.

such a conformation should be stabilised against inactivation by procedures not inducing covalent changes in the primary structure. To maintain interferon in such a state, we selected a system consisting of urea, 2-mercaptoethanol, and the sodium dodecyl sulphate (SDS). The first two agents should provide random coils, which would theoretically be reversibly denatured, but in practice, oxidation of sulphydryl groups or exchange of sulphydryl and disulphide bonds are almost unavoidable upon their removal[3]. SDS should, however, defend the reactive groups against interactions[5].

Mouse interferon prepared in L_{929} cells induced with Newcastle disease virus was acidified to *p*H 2, extraneous proteins were precipitated by addition of ammonium sulphate to 20% saturation at 20° C, and clarified supernatant fluid was adjusted to *p*H 7.2 by dialysis against 0.01 M Tris HCl buffer. Prepara-

Table 1 Labilities of unfolded and reduced interferons under conditions allowing intra and intermolecular interaction

	Reagent	Initially	$\log_{10}$ Activity After 56° C 30 min	After 100° C 2 min
Mouse interferon	None	3.8	3.0	< 1
	Mercaptoethanol (1.4×10^{-2} M)	3.5	1.5	< 1
	Urea (5 M)	3.3	1.0	< 1
	Mercaptoethanol + urea	3.0	< 1	< 1
Human interferon	None	4.0	3.5	< 1
	Mercaptoethanol	3.8	1.5	< 1
	Urea	3.5	1.5	< 1
	Mercaptoethanol + urea	2.8	< 1	< 1

tions had specific activities of about 10^6 units per mg protein. Human interferon produced in human diploid fibroblast cells induced with poly(I)·poly(C) was dialysed against 0.01 M Tris HCl buffer, *p*H 7.2.

The labilities of mouse and human interferons to various denaturation procedures were remarkably similar (Fig. 1). Heat inactivation kinetics of mouse interferons were independent of the purity of the preparation: preparations with about 10^4, 10^5, 10^6 or 10^7 units per mg protein showed identical inactivation kinetics.

The interferons were only slightly affected by either urea or mercaptoethanol at room temperature and exhibited the same 100° C heat lability in their presence as was seen in their absence; at 56° C, these agents markedly accelerated the inactivation rate (Table 1). The combination of urea and mercaptoethanol caused a greater loss of initial activity and, again, had no stabilising effect on the residual activity. Interferons denatured under these conditions seemingly allow intramolecular and intermolecular interplay.

Addition of SDS to denatured, reduced proteins might be expected to defend against this random, nonselective interplay of reactive groups which presumably contributed to the seemingly irreversible denaturation. Reduced proteins dissociated by urea and SDS seem to stay dissociated in SDS after removal of the unfolding and reducing agents[6,7]. Both human and mouse interferons in the SDS-'defended' state were completely stable to heat and freeze-thaw cycles (Fig. 1). 'Defensive' reversible denaturation was achieved by making the interferons 3.5×10^{-3} M SDS, 1.4×10^{-2} M 2-mercaptoethanol and 5 M urea; in other experiments 3.5×10^{-2} M SDS, 1.4×10^{-1} M 2-mercaptoethanol and 5 M urea gave identical results. Presumably, interferons in this condition are converted to linear peptide chains and after removal of urea, mercaptoethanol and excess SDS by dialysis, the SDS–interferon remains dissociated and returns to an active conformation when incubated with protein-containing medium. Significantly, addition of SDS alone to the interferons reduced their activities by between 60 and 90%, but the residual activity was stabilised in the presence of SDS alone. This suggests that interferons can renature to some extent from configurations that have cross-linked peptide chains, but can renature more efficiently from the linear polypeptide supposedly attained in SDS, urea and mercaptoethanol. Alternatively, this could suggest there are two distinct molecular species in these interferon preparations and that the major component does not renature after treatment with SDS alone, but does so if it is unfolded in SDS and mercaptoethanol, while the minor component is able to unfold in SDS alone and to renature. Since there are no known protein aggregates linked by noncovalent bonds that survive treatment with SDS at 100° C for 1 min (ref. 5), this stabilising process allows the determination of the molecular species of dissociated, denatured and reduced interferons by SDS–polyacrylamide gel electrophoresis and the relative biological (antiviral as against nonantiviral)[8] properties resident in the renatured molecular species of interferons.

Surface H-2 antigen concentration requirement of somatic hybrid cells for IgM-mediated cytotoxicity

THE immune response following grafting of allogeneic or semiallogeneic cells in the mouse is characterised by the development of cytotoxic effector lymphocytes and/or antibodies which become cytotoxic *in vitro* in the presence of complement. I have studied the kinetics of the humoral response in DBA/2 inbred mice injected with semiallogeneic somatic cell hybrids and shown that these hybrid cells were unexpectedly resistant to the complement-dependent cytotoxic action of antisera from the initial peak of the biphasic response. The allogeneic parental cells were however highly sensitive to cytolysis under the same experimental conditions. This serological response seems to be directed against the H-2 alloantigens expressed on both the allogeneic parental cells and on the semiallogeneic hybrid cells derived from it. In my attempts to understand this phenomenon, I found that the mouse alloantibodies of the IgM and IgG classes have different efficiencies when tested in the cytotoxic test on cells having a low H-2 antigen concentration on their plasma membrane.

Sera from the first peak (which extended from days 6-9 after injection of Y2C hybrid cells exhibited a clear cytotoxic effect when tested against the allogeneic parental cell C1 1D (sera 1, Table 1). The mean titre, defined as the dilution of serum at which 50% of chromium was released into the supernatant, was 1:32. But when labelled Y2C cells were the target cells, most of these sera did not liberate significantly more chromium than the chromium release background. (Background release was measured in controls where Y2C cells were incubated with complement alone, or with complement and serum from non-immunised DBA/2 mice). Sera from hyperimmunised mice, however, were equally effective against both C1 1D and Y2C cells. The mean titre for C1 1D was 1:128; for Y2C cells, 1:256 (sera 2, Table 1).

This response was directed mainly against the $H\text{-}2^k$ transplantation antigens as was demonstrated by immunoabsorp-

Table 1 Cytotoxic activity of antisera as a function of antibody size and target cell use

Antisera group	Cell injected	Immunised strain	H-2 antigens against which antibodies were made	Antibody size	Target cell	Mean antisera titres
1*	Y2C	DBA/2	H-2^k	19S	C11D	1:32
					Y2C	< 1:4
2†	YC2	DBA/2	H-2^k	19S	311D	1:128
				7S	Y2C	1:256
3	C3H lymphocytes	BALB/c	H-2^k	7S	C11D	1:2,048
					Y2C	1:2,048
4	DBA/2 lymphocytes	C3H	H-2^d	7S	L1210	1:2,048
					Y2C	1:2,048
5	(C3H × DBA/2)F1 lymphocytes	B10.M	H-2^k		L1210	1:4
			H-2^d	19S	C11D	1:4
					Y2C	1:4

* Sixteen individual antisera were tested.

† Produced by nine weekly i.p. injections of 3 × 10^6 Y2C cells. Sera from eight different mice were tested.

For groups 1 and 2 Y2C hybrid clone was derived from the fusion of L1210-R lymphocytic leukaemia cells of DBA/2 mouse origin (H2^d) (ref. 1) with LM(TK$^-$) C1 1D cells, a subclone of C3H mouse L cell line (H2^k) (ref. 2). Cells were fused using ultraviolet-inactivated Sendai virus[3]. The isolation and culture conditions for *in vitro* growth of the hybrid clones have been described elsewhere[4]. C1 1D and L1210 parental and Y2C hybrid cells were propagated in culture in Dulbecco's modified Eagle's medium with 10% heat-inactivated calf serum. The cells (except L1210 cells which grew in suspension cultures) were dispersed with 0.02% versene in Dulbecco's phosphate buffered saline (PBS) rinsed with PBS and suspended in Dulbecco's medium. Three month old DBA/2 mice were inoculated subcutaneously with 3 × 10^6 viable Y2C hybrid cells and bled daily; sera were stored at −20° C until tested. Their activity was measured as complement-dependent cytotoxicity by the chromium release test[5]. One millilitre of a target cell suspension (5 × 10^6 viable cells ml^{-1}) was incubated at 37° C for 30 min with 200 μCi sodium chromate (^{51}Cr) and washed exhaustively with Dulbecco's modified Eagle's medium supplemented with 10% heat-inactivated foetal bovine serum. 1 × 10^5 labelled cells were incubated with serial two-fold dilutions of antisera in the presence of rabbit serum (diluted 1:10) as a source of complement, in a final volume of 0.25 ml. At the end of the incubation period (1 h at 37° C in a 5% CO_2 atmosphere), 1.75 ml of ice-cold PBS was added to each tube, and after centrifugation, 1 ml of the supernatant was assayed for released chromium in a well-type gamma radioactivity counter.

tion experiments. Some cytotoxic activity remained after the absorption of hyperimmunised DBA/2 mice sera with C3H mouse splenic lymphocytes; this residual cytotoxicity might be directed against the virus-induced antigens on the L cell line[6], and in hybrid cells in which L cell derivatives (C1 1D) were partners[7–9].

The sizes of the antibodies for the initial and second peak were studied by fractionating the sera at 4° C on a Sephadex G-200 column (1.5×60 cm) equilibrated with PBS. Fractions were concentrated by B 15 Minicon ultrafiltration (Amicon) and tested immediately for cytotoxicity against ^{51}Cr-labelled cells. Only 19S antibodies could be found in the initial peak of the immune response; both 19S and 7S antibodies of approximately equal cytotoxic titres coexisted in the sera from the hyperimmunised mice. When tested for sensitivity to 2-mercaptoethanol, the 19S fraction completely lost its activity but the cytotoxicity of the 7S fraction was only slightly reduced.

In another experiment, both parental and hybrid cells were titred by alloantisera specifically directed against the H-2^d and the H-2^k transplantation antigens. Antisera, made in BALB/c and C3H inbred mice by hyperimmunisation with lymphnode and splenic lymphocytes of C3H and DBA/2 origin, respectively, were tested against target cells. Fractionation of these sera showed that the bulk of the activity was due to molecules of the 7S class. The titres were 1:2,048 when tested against the lymphocytes used in the immunisation. The same high activity was found when titred against the allogeneic parental cell and the Y2C somatic hybrid (sera 3 and 4, Table I) demonstrating that, in accordance with other reports[7–9], the hybrid clone expresses major histocompatibility antigens of both strains of mice from which the parental cells were derived and that Y2C cells were very actively lysed by 7S antibodies. Furthermore, when those antisera were tested on Y2C cells by the indirect immunofluorescence technique, a clear positive reaction was observed on 97% of cells.

Since some reports have stated that mouse 19S antibodies react preferentially with guinea pig complement[10], the cytotoxic test with sera from group 1 was performed in the presence of fresh rat (diluted 1:4) and lyophilised guinea pig sera (1:2) as a source of complement. No improvement was found in ^{51}Cr release when such complements were used instead of rabbit complement.

As antigen masking by sialic acid may occur in both normal cells and tumour cells[11,12], removing sialic acid from Y2C cell surfaces by neuraminidase might improve the cytotoxic activity of IgM. Five million labelled Y2C hybrid cells were incubated with 5 IU of *Vibrio cholerae* neuraminidase (Behringwerke) for 20 min at 37° C in 1 ml of PBS (*p*H 6.5). After washing, the viability was determined by trypan blue dye exclusion and cells were assayed for susceptibility to 19S-mediated cytotoxic effect. Neuraminidase-treated cells became more sensitive to the action of IgM (mean titres changed from < 1:4 to 1:8) presumably as the result of the re-exposure of antigenic determinants, with the concomitant increase in complement-fixing sites.

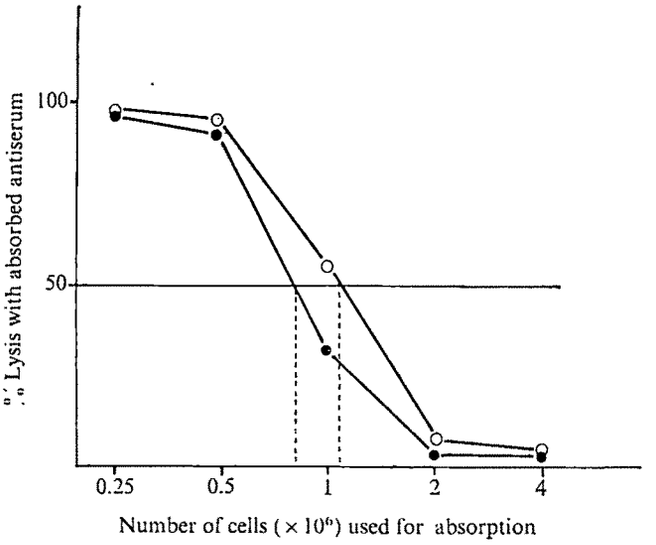

Fig. 1 Antibody binding capacity of C1 1D and Y2C cells. Serum 3, diluted to give a 90–95% cytotoxic activity was absorbed with increasing numbers of cells at 37° C for 30 min and then allowed to stand for 30 min at 4° C. After centrifugation, the remaining activity of the supernatant was tested against the appropriate sensitive cells. The values are based on the results of three experiments. ●, C1 1D; ○, Y2C

When target cells were tested against 19S antibodies from adult B10M inbred mice injected with 8×10^7 splenic cells of (C3H×DBA/2) F_1 hybrid mice and bled 4 d after the injection, a weak but uniform response was found (sera 5, Table 1) the increase in the number of target sites leading to an enhanced susceptibility to lysis in Y2C cells.

The quantitative differences in H-2^k antigen concentration on the plasma membrane from C1 1D and Y2C cells were then investigated by studying the absorption capacity of intact viable cells. Figure 1 shows that the H-2^k antigen concentration on C1 1D cells was approximately 1.5 times greater than on the hybrid cells. Diameters of both cell types were measured with an ocular micrometer (200 cells of each sample), and the ratio of surface area of Y2C cells to that of C1 1D fibroblasts was calculated to be 5:4 (i.e. 20% greater). It seems therefore that the H-2^k antigenic density on Y2C cells is about 55% of that on the C1 1D plasma membrane, if uniform surface smoothness is assumed.

An inverse relationship between the quantitative expression of H-2 and tumour-specific antigens has been demonstrated by some authors[13–15]. In somatic hybrid cells it is possible that all the antigenic determinants of both parental cells are expressed on the cell surface. In addition to the H-2^k antigenic complex and the L antigen, C1 1D express some group-specific murine leukemia antigens[6]. L1210 cells may contribute to the Y2C antigenic constitution with the H-2^d isoantigen complex and also with its tumour-specific transplantation antigens[16]. Thus there is competition for the plasma membrane surface in hybrid cells, resulting in a topographic exclusion of some antigens.

As the immune lysis of mouse leukemic cells by IgM is a 'one-hit' reaction[17], the relative resistance of Y2C hybrid to the 19S antibody-mediated lysis might be due to the great difference between the number of complement-fixing sites and lytic sites available on the plasma membrane. In fact, 3,000 complement C1-fixing sites were necessary to generate one lytic site on the surface of a mouse leukaemic cell, the IgG being more effective in generating C1-fixing sites[17]. The restricted expression of H-2 antigens on the surface of Y2C somatic cell hybrids seems to be responsible for the lack of sensitivity to lysis mediated by IgM antibodies[18]. Moreover, a critically spaced repeating H-2 determinant on the plasma membrane must be required for the induction of complement-dependent cytotoxic effect.

Thus, caution should be exercised in interpreting results of studies carried out with the cytoxicity assay on cell populations with a low density of transplantation antigens (that is, tumour-specific antigens) on the cell surface.

I thank Dr R. Motta, Institute de Cancérologie et d'Immunogénétique, Villejuif, for providing the sera 3 and 4, and the B10.M strain. I am supported by the World Health Organisation.

Subunit structure of HL-A antigens on cell surface

THE major human histocompatibility determinants, the HL-A antigens, are cell surface markers present on lymphocytes and most other nucleated cells (compare ref. 1). Recently, work from two laboratories has indicated that HL-A antigens, released from the cell surface by means of papain digestion, are composed of two polypeptide chains[2,3]. The smaller of the two subunits seems to be invariant regardless of the antigenic specificity carried by the larger HL-A chain[2,3] and occurs in human biological fluids[4].

It had previously been demonstrated that β_2 microglobulin exhibits extensive amino acid sequence homologies with immunoglobulin heavy and light chains[5,6] and that β_2 microglobulin is an integral part of the cell surface[5,7,8]. In a search for its function we showed that β_2 microglobulin was one of the two HL-A polypeptide chains[9]. Independently, Nakamuro *et al.*[10] demonstrated that the small HL-A chain shared some properties with β_2 microglobulin.

Here we present evidence that β_2 microglobulin and the alloantigenic HL-A chain are physically linked to each other on the cell surface of lymphocytes.

Purified lymphocytes were isolated from defibrinated blood by Ficoll-Isopaque gradient centrifugation[11,12]. The blood was obtained from healthy blood donors with known HL-A phenotype. The cells were subjected to the microlymphocytotoxicity test[13] with purified anti-β_2 microglobulin antibodies[14], and cells from all donors were completely lysed regardless of their HL-A phenotype[9,15,16].

It was argued that if β_2 microglobulin and the alloantigen-carrying HL-A chain are indeed parts of the same molecule, antibodies directed against one of the polypeptide chains may interfere with the simultaneous binding of antibodies to the other chain. The results of experiments designed to test this possibility are summarised in Table 1. Fab′ fragments[17] against β_2 microglobulin could completely and specifically inhibit the cytotoxic action of bivalent anti-β_2 microglobulin antibodies. In control experiments, Fab′ fragments against light immunoglobulin chains had no effect. Fab′ fragments directed against various HL-A determinants could specifically inhibit the cytotoxic action of the corresponding bivalent antibodies but not if the anti-HL-A antibodies were directed against some other specificity. A number of monospecific anti-HL-A antibodies could not cause lysis of cells that had been pretreated with Fab′ fragments against β_2 microglobulin (Table 1), whereas their cytotoxic activity was normal when tested against cells treated with Fab′ fragments against immunoglobulin light chains. Cells derived from a doubly homozygous donor, that is, expressing only one serological specificity for each HL-A sublocus, were separately treated with Fab′ fragments directed against one

Table 1 Effects of Fab′ fragments on the lymphocytotoxic effect of anti-β_2 microglobulin and anti-HL-A antibodies*

Specificity of Fab′ fragments†	Specificity of antibodies	Cytotoxic effect‡
— — —	β_2M	++++
β_2 Microglobulin	β_2M	−

HL-A 1, 8	β_2M	++

* The cells were incubated for 45 min at 37° C in Eagles' MEM with various concentrations of the Fab′ fragments indicated, washed three times in the medium before being subjected to the cytotoxicity test[13]. The concentrations of the Fab′ fragments and the cytotoxic antibodies used were chosen such that a two-fold dilution of the working solutions notably diminished their blocking or cytotoxic activity, respectively.

† The target cells used in the present experiment were from a donor homozygous for the HL-A antigenic specificities 1 and 8. In a number of identical experiments, results similar to those listed were obtained with anti-HL-A antibodies of specificities 2,7,10,11,27, W10, and W15.

‡ The cells were scored ++++ if more than 75%, +++ if more than 50%, ++ if more than 25%, + if more than 15%, and − if less than 15% of the cells were stained by trypan blue.

of the two HL-A specificities. A slight but significant reduction in the cytotoxic activity of anti-β_2-microglobulin antibodies compared with untreated control cells was noted. If, however, the cells were simultaneously treated with a mixture of Fab′ fragments directed against each of the two subloci gene products, the cytotoxicity was substantially reduced. Thus, β_2 microglobulin and the alloantigenic, larger HL-A polypeptide chain are located in close proximity on the cell surface.

Attempts were made to demonstrate simultaneous redistribution of β_2 microglobulin and the alloantigenic HL-A chain on the surface of purified lymphocytes to show that the two polypeptide chains are physically linked to each other.

Fluorescein isothiocyanate (FITC)-conjugated anti-β_2 microglobulin antibodies[18] were incubated together with purified lymphocytes. Details of the materials used have been described elsewhere[19] and the experimental protocol was essentially that of Kourilsky *et al.*[20]. Anti-β_2 microglobulin fluorescence was present on more than 90% of the nucleated cells (compare Table 2). A majority of the cells had patches and a few displayed polar caps. If, however, the FITC-anti-β_2 microglobulin antibody-treated cells were incubated with goat-anti-rabbit immunoglobulin (GARIG) antibodies, rendered specific against the Fc portion of the molecule by thorough absorption with rabbit Fab′ fragments, more than 70% of the stained cells exhibited fluorescent caps. FITC-anti-β_2 microglobulin Fab′ fragments gave diffusely distributed fluorescence both in the absence and presence of GARIG. In control experiments with use of FITC-rabbit-anti-human immunoglobulin (RAHIG) antibodies and GARIG treatment, all fluorescent cells showed caps. This cap formation did not, however, induce any redistribution of FITC-anti-β_2 microglobulin Fab′ fragments, thus establishing that β_2 microglobulin on the cell surface is quite independent from cell membrane-bound immunoglobulins.

FITC-conjugated anti-HL-A antibodies of different specificities gave rise to cells exhibiting patches or caps. The cap formation was more pronounced in the presence of RAHIG. Only diffuse fluorescence was evident on cells treated with anti-HL-A Fab′ fragments whether GARIG had been added or not.

Attempts were made to induce patch and cap formation of FITC-anti-HL-A Fab′ fragments with successive treatment of the cells with anti-β_2 microglobulin antibodies and GARIG. The anti-β_2 microglobulin antibodies, obtained from rabbits immunised with free β_2 microglobulin, did not cause any redistribution of the diffuse fluorescence but rather seemed to displace a large proportion of the fluorescence from the cell surface. This could, however, be explained by the above results on the inhibition of the anti-β_2 microglobulin antibody-induced lymphocytotoxicity (Table 1). Anti-β_2 microglobulin antibodies were therefore obtained from a rabbit immunised with highly purified, papain-solubilised HLA antigens and isolated by immunosorbent purification[21]. These anti-β_2 microglobulin antibodies together with FITC-anti-HL-A Fab′ fragments and GARIG induced caps in all experiments (Table 2).

Cells incubated with FITC-anti-β_2 microglobulin Fab′ fragments, obtained from the rabbit anti-HL-A serum, as described above, were treated in succession first with anti-HL-A antibodies and then with RAHIG. A significent number of cells (> 60%) exhibited patches and with some anti-HL-A antibodies even caps (Table 2). In all experiments, however, a few cells always showed only a diffuse fluorescence.

These experiments clearly demonstrate that β_2 microglobulin and the alloantigenic HL-A polypeptide chain are physically linked on the lymphocyte surface.

As the β_2 microglobulin amino acid sequence is highly homologous to immunoglobulin light and heavy chains[5,6], it has been suggested that it is an evolutionary precursor to regular immunoglobulin polypeptide chains[5]. It now seems possible that at least part of the alloantigens and the immunoglobulins may have arisen from a common evolutionary origin[9,22].

We thank Yvonne Fernstedt and Gun Jönsson for technical assistance. This work was supported by grants from the

Table 2 Effects of various antibodies on the redistribution of the antigen-carrying HL-A chain and β_2 microglobulin on the cell surface.

Approximately 2 × 10^6 cells were incubated for 30 min at 37° C in 0.2 ml of Eagles' MEM containing an appropriate concentration of the FITC-conjugated component (1–4 mg ml^{-1}). At the end of the incubation period, the cells were washed three times with the medium, and examined in a Leitz Ortholux microscope equipped with a HBO 200 W lamp. The Ploem-type vertical illuminator and immersion objectives were used. If further treatment of the cells was required they were incubated with antibodies (3–8 mg ml^{-1}) in Eagles' MEM for another 30 min, washed three times with the medium, examined in the fluorescence microscope or incubated with GARIG or RAHIG (3–5 mg ml^{-1}) for another 30 min in Eagles' MEM before evaluation of the cell-surface bound fluorescence.

† If more than 20% of the fluorescent cells showed a certain type of distribution of the label, they were scored as positive.

Evidence that mitogenic lectins induce changes in lymphocyte membrane fluidity

MITOGENIC plant lectins, such as phytohaemagglutinin (PHA) and concanavalin A (con A), are useful tools to study the control of cell proliferation in lymphocytes. Recent evidence suggests that these mitogenic lectins trigger mitogenesis at the cell membrane[1,2]. It is likely that an understanding of the mechanisms by which these lectins stimulate lymphocytes will provide important clues to more general problems of the regulation of proliferation in eukaryotic cells.

A model has been proposed to explain how modulation of membrane structure may influence cell growth. This model suggests that changes in the fluid characteristics of membrane lipids affect a variety of membrane activities[3–5]. Studies in isolated membranes have shown, for example, that fluidisation of membrane lipids is associated with activation of Na^+, K^+-ATPase[3]. *In vitro* studies have also correlated a fluid state of membrane lipids in transformed cells with high cellular levels of cyclic GMP and low levels of cyclic AMP and ordered membrane lipids in contact inhibited cells with low levels of cyclic GMP and high levels of cyclic AMP[4,6–9].

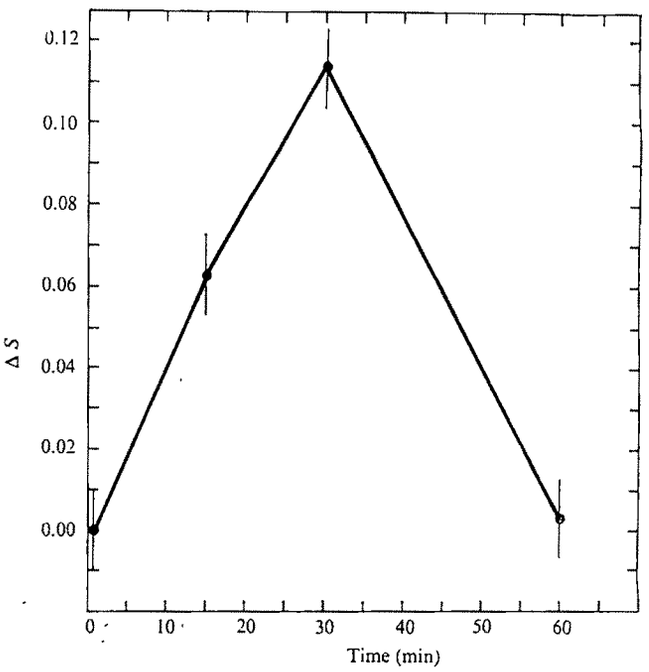

Fig. 1 The effect of an optimal mitogenic dose of PHA-P (Difco, 7.5 $\mu g\ ml^{-1}$) on the fluidity of the human lymphocyte membrane at various times after addition of the mitogen. $\Delta S = S_{control} - S_{PHA}$ and $S_{control} = 0.52$.

In lymphocytes recent observations suggest that mitogens also induce an early increase in levels of cyclic GMP[10]. This nucleotide increases more than ten-fold within 5–20 min of the addition of PHA or con A, followed by a decline to basal levels within 1 h. Other mitogenic agents such as phorbol myristate acetate[8] and high concentrations of insulin[9] also increase considerably the levels of cylic GMP in lymphoid cells. It has been suggested that this increase is part of the signal to initiate cellular proliferation. After binding of mitogenic lectins other early changes in the plasma membrane occur; examples are increased endocytosis[11] and incorporation of orthophosphate into phosphatidyl inositol[12].

According to our membrane model[3–5], lymphocyte mitogens which produce a transient elevation of cellular cyclic GMP should fluidise membrane lipids. The data reported here support this model.

Human peripheral blood lymphocytes, separated using a Ficoll-Hypaque density gradient, were 90% free of contaminating monocytes, erythrocytes and granulocytes. Mouse lymphocytes were obtained from CBA/Ht6 strain spleen cells which were minced and washed three times in buffered saline. The fluid characteristics of the plasma membrane of lymphocytes were probed with the spin label sodium 6-(4′,4′-dimethyloxazolidinyl-N-oxyl)-heptadecanoate[3]. A 0.3 mM solution of the label in buffered saline was incubated with cells for 30 min at 37° C. The cells were then washed five times to remove excess label[13]. The electron paramagnetic resonance (EPR) spectra were recorded at 33° C with a Varian E-3 spectrometer.

The EPR spectra of the spin-labelled fatty acids in natural membranes indicate that the labels have two important characteristics: (1) they undergo rapid anisotropic motion about an axis approximately parallel to the fatty acid chain with a correlation time of $<<10^{-7}$ s[3,14–18] and (2) they undergo rapid lateral diffusion with a diffusion constant of 10^{-8}–10^{-7} $cm^2\ s^{-1}$ (refs 19–22). Since it is improbable that such rapid axial motion or rapid lateral diffusion could occur if the labels were bound to protein, these characteristics suggest that the labels are in a phospholipid bilayer-like environment. While the lateral

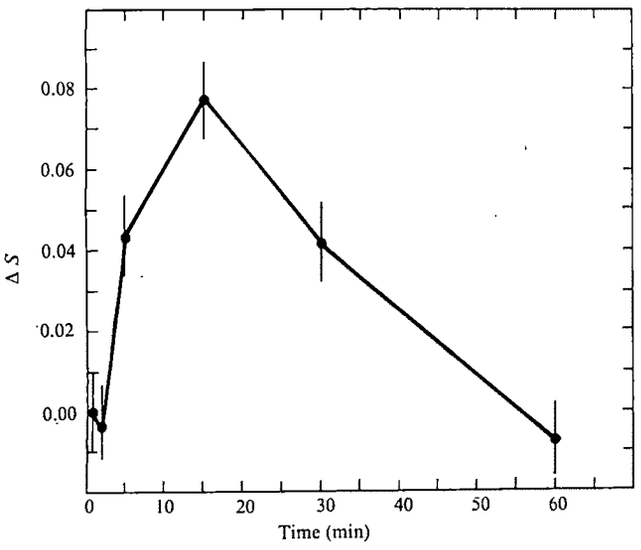

Fig. 2 The effect of con A (Difco, 3 μg ml^{-1}) on the fluidity of the plasma membrane of mouse splenic lymphocytes at various times after addition of the Mitogen. $\Delta S = S_{control} - S_{Con\ A}$ and $S_{control} = 0.52$.

diffusion of surface antigens in mouse-human heterokaryons throughout the cell membrane requires about 40 min[23], that for spin labels of fatty acids should require about 1 s.

Order parameters, S, were calculated from the EPR spectra. Values of S near 1 correspond to an ordered state of the membrane lipids while values near 0 correspond to a fluid state[24]. With the label used in this study, a $\Delta S = 0.03$ would be equivalent to a change in membrane fluidity produced by a 6–10° C temperature change[3].

The data in Figs 1 and 2 clearly demonstrate that treatment of human peripheral lymphocytes with mitogenic concentrations of PHA and treatment of mouse splenic lymphocytes with mitogenic concentrations of con A produce a fluidisation of membrane lipids. Both human and mouse lymphocytes showed maximal fluidisation between 15 and 30 min. The dose-response curve for membrane fluidisation also corresponds well with the dose-response curve for the mitogenic effect of con A (Fig. 3). In contrast, a nonmitogenic lectin, wheat germ agglutinin, had no effect on membrane fluidity.

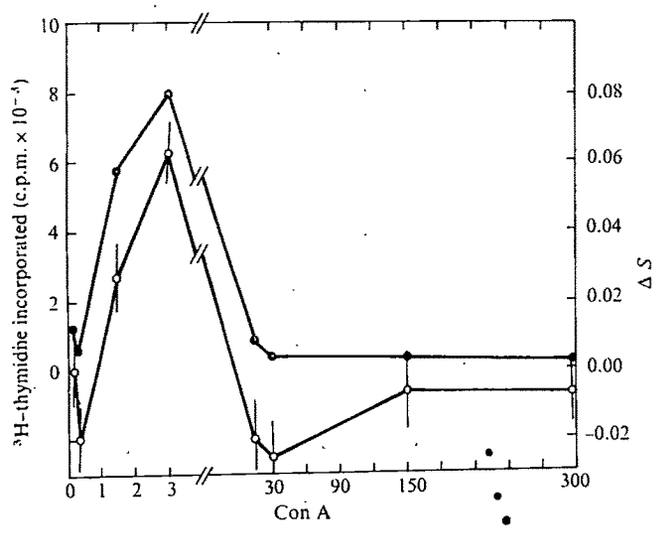

Fig. 3 The dose-response curves for the mitogenic effects of con A (●) and the membrane fluidising effect of con A for a 20 min incubation (○) with mouse splenic lymphocytes. Mitogenesis was determined by incorporation of ^{3}H-thymidine into acid-insoluble precipitate after 72 h of incubation.

Studies are in progress to define precisely the location and distribution of the label in lymphocyte membranes, and to examine other mitogenic agents to determine whether critical membrane fluidisation is a perequisite for mitogenesis in general. The data presented here demonstrate, however, that only mitogenic concentrations of plant lectins produce an early fluidisation of lymphocyte membranes and that the time of membrane fluidisation closely parallels the increase and decrease of cyclic GMP levels in stimulated lymphocytes[10]. It has been suggested that the increase of cellular cyclic GMP levels is a signal for cellular proliferation[7–10] and our data suggests that early membrane fluidisation may be equally important in the triggering process.

Hb K Woolwich the cause of a thalassaemia

In general terms, heterozygotes for β thalassaemia have a moderate degree of microcytosis associated with an elevated red cell count, a reduced mean cell volume (MCV) and mean cell haemoglobin (MCH) and a normal, or near normal, mean cell haemoglobin concentration (MCHC). The chief diagnostic parameter of the heterozygous state is, however, the elevated Hb A_2 level which accompanies the condition. This does not occur in other haemoglobinopathies with the exception of those associated with unstable haemoglobins and some heterozygotes for Hb S (ref. 1) and Hb C (ref. 2). At the molecular level β thalassaemia is associated with an imbalance of globin chain synthesis during erythroid cell maturation, as a result of defective β chain synthesis. The extent of the defect parallels the severity of the thalassaemia, ranging from a reduction in the amount of product from the affected β chain locus (β^+ thal) to no product (β^0 thal). In all cases of β^+ thal so investigated, the β chains produced by the affected gene have been indistinguisnable from normal β^A chains.

We here present evidence which compares the inheritance of the β chain gene of Hb K Woolwich (Hb KW) with the inheritance of a β^+ thalassaemia. Also, the interaction of this thalassaemia with an α thalassaemia is demonstrated in a patient of West Indian origin.

Hb KW, first described in a West Indian family, is a stable haemoglobin variant[3]. Table 1 gives the pattern of haemoglobins in seven heterozygotes for Hb KW characterised in this laboratory. The amount of Hb KW is always proportionately less than the other adult haemoglobin (30–40%) and the Hb A_2 is higher than normal in six of the seven cases. The R family (Fig. 1) was available for more detailed haematological investigations. The propositus I–1 had the classical features of β thalassaemia trait; a moderate microcytosis and a high Hb A_2 level in the red cells (Table 1). Investigation of the abnormal haemoglobin identified it as Hb K Woolwich, although β-chain variants usually exceed 50% of the total haemoglobin in double heterozygotes for β thalassaemia and a β-chain variant[2,4]. Nevertheless, the pattern was repeated in members of the family who had inherited the β^{KW} chain gene; they all had high levels of Hb A_2 per red cell (Table 1). The doubly abnormal heterozygote, (Hb KW+Hb S), II–3, had an exceptionally high Hb A_2 but the difference can be accounted for by the additional inheritance of the β^S chain gene, which is often associated with marginally higher levels of Hb A_2 per cell than normal[1] (Table 1).

The conclusion from these observations is that inheritance of the β^{KW} chain gene is associated with a mild β thalassaemia, that is the β^{KW} chain locus is a β^{KW+} thalassaemia gene. This is the first example of a β^+ thalassaemia in which the product of the affected locus is distinguishable from the normal β^A chain.

Since the normal course, in suspected cases of thalassaemia, is an investigation of the *in vitro* biosynthesis of the globin chains, a reticulocyte-rich preparation of red cells was obtained from the blood of the propositus. The results of *in vitro* incorporation of ^{3}H-leucine into the α^A, β^A and β^{KW} chains isolated from the whole globin of these red cells are summarised in Fig. 2. The incorporation of radio-isotope into all chains was linear over the incubation period of 60 min. The total incorporation of ^{3}H-leucine into the β^{KW} chain was always much less than into the β^A chain and averaged less than 50% of the incorporation into the β^A chain (Table 2). The amount of Hb K Woolwich found in the blood of the propositus is therefore an accurate reflection of the amount of this chain synthesised during erythroid cell maturation. This fulfills another criterion required by the definition of β thalassaemia; namely the demonstration of defective synthesis of globin chains by one of the β chain loci.

Table 2 *In vitro* biosynthesis of α, β^A and β^{KW} chains in reticulocytes from propositus

Incubation Time (min)	3	6	9	15	30	60	Mean
$\beta^{KW}/\beta\alpha+\beta^{KW}$	0.29	0.36	0.34	0.31	0.30	0.30	0.30
α^A/β^A	1.30	1.20	1.20	1.10	1.00	1.10	1.20
$\alpha^A/\beta^A+\beta^{KW}$	0.93	0.80	0.78	0.79	0.73	0.74	0.79

The ratios correspond to the relative amounts of each chain synthesised based on the total incorporation of ^{3}H-leucine into the individual chains during *in vitro* incubation of the reticulocytes.

A correlation between the mutation in the $\beta^{K\ Woolwich}$ chain β 132 (H10) Lys–Gln and the lesion responsible for the amount synthesised is important since this could confirm the predictions on one possible cause of β thalassaemia based on a "structure-rate hypothesis"[5]. There are several observations in favour of this explanation: (1) Hb K Woolwich is the only known haemoglobin variant resulting from a mutation at H10 Lys; (2) with the exception of the frog, where it is alanine, in all species so far examined, lysine (H10) is an invariant residue in all α, β^6 and myoglobin chains[6,7]; and (3) a myoglobin variant has been characterised in which H10 Lys is replaced by a residue of asparagine and the amount of the myoglobin variant in muscle extracts is approximately 30% of the total myoglobin[8].

It is possible that the tRNA coding for the β H10 glutamine is in short supply. This would introduce a partial block at position H10 and decrease the rate of translation of the β chain mRNA by the ribosomes. This possibility was investigated by comparing the rate of assembly and termination of the β^A and β^{KW} chains by a modification of the method of Dintzis[9] (Table 3 and Fig. 3). From Fig. 3,

The haemoglobins were quantitatively estimated by DEAE Sephadex chromatography[15]. Globin prepared from Hb KW (ref. 6), was separated into the individual chains by ion exchange chromotography on CM 23 cellulose[17]. The β^{KW} chain was characterised as β132 (H10) Lys–Gln by fingerprinting the trypticpeptides, elution, hydrolysis and amino acid analysis of the abnormal peptide[3]. Haematological data were obtained from a Coulter S counter.

Experimental data are given in Fig. 3. In column 1, the numbers in parentheses refer to the leucine residues expected in each peptide. Blanks were obtained from three different areas in each fingerprint.

the computed values of the specific activities of the N-terminal and C-terminal amino acids of both chains are approximately the same after 6 and 9 min incubation of the reticulocytes with ^{3}H-leucine. Therefore, the rate of incorporation of isotope into the N-terminal residue relative to the C-terminal residues is the same for both chains, indicating no reduction in the rate of assembly or termination of the β chain as a result of the mutation. Other mechanisms by which the amount of gene product could be reduced are a decreased rate of initiation of β^{KW} chain synthesis on the mRNA and a decreased amount of available mRNA as a result of either instability of the mRNA, or a reduced rate of transcription of the abnormal locus. The available data on translation and transcription in eukaryotes do not offer any reason why a change of nucleotide at this position of the structural gene should result in a reduced amount of product. If we speculate, however, and there is a precedent in known tRNAs (ref. 6) that mRNA normally assumes a stable secondary structure dictated by the nucleotide sequence, then there is a mechanism by which initiation of mRNA could be responsible for the low levels of β^{KW}. For example, the nucleotide sequence around the codon for β 132 (H10) lysine could be important in the maintenance of the proposed secondary structure of the mRNA, such that the initiation codon (AUG) was freely available for reaction with the available ribosomal subunits. The nucleotide change responsible for the mutation Lys–Gln, that is, the transversion A–C, could conceivably alter the secondary structure sufficiently to make the initiation codon less available for interaction. By the same argument, the normal codon could also be involved in the maintenance of a stable secondary structure which contributes to the protection of the mRNA during transport from the nucleus. Then the transversion (A–C) could so reduce the stability of configuration that the normal amount of mRNA is prevented from reaching the cytoplasm and the ribosomes.

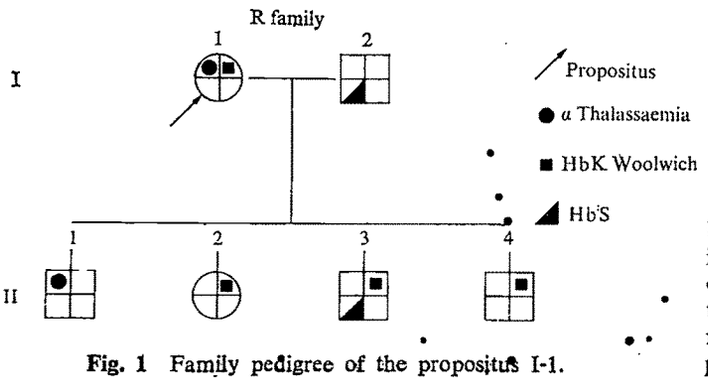

Fig. 1 Family pedigree of the propositus I-1.

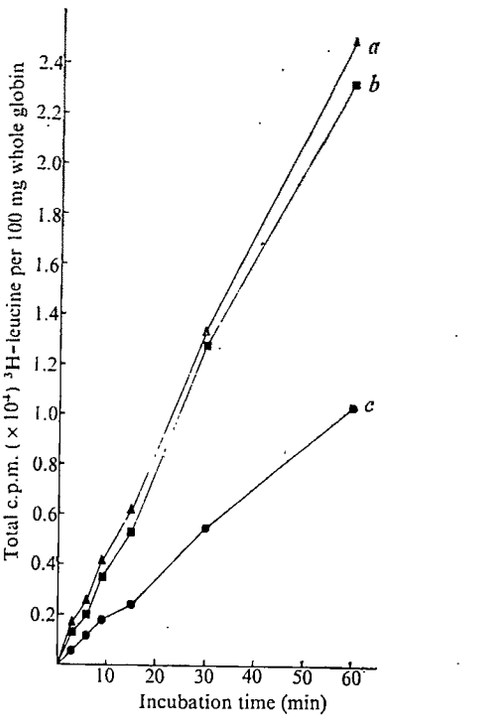

Fig. 2 *In vitro* incorporation of ^{3}H-leucine into the α, β and β^{KW} chains of the propositus. Reticulocyte-rich red cells prepared from the blood of the propositus[12] were pre-incubated for 15 min at 37° C in the medium of Lingrel and Borsook[13]. 250 μCi ^{3}H-leucine (0.007 μmol) were added and samples of cells removed at time intervals from 3–60 min then added to a ten-fold excess of ice cold isotonic saline. The cells were washed several times, lysed and the haemolysate added directly to acid acetone at −20° C. The globin chains from 100 mg whole globin samples were separated on Whatman CM23 cellulose using a linear gradient of Na^+ in 8 M urea[17] *p*H 6.7. The protein fractions corresponding to the α, β and β^{KW} chains were pooled separately and dialysed against 4 × 10 l 0.5% formic acid. The total volume of each solution was measured by weight and aliquots were added to 15 ml of scintillator solution (Triton X100, 500 ml; toluene, 1,000 ml; PPO 5 g) (ref. 14) and counted in a 'Tracerlab Coru Matic 200' liquid scintillation spectrometer. *a*, α chain; *b* β^A chain; *c* β^{KW} chain.

The propositus I–1 had the additional complication that, besides the signs of a β^+ thalassaemia, the overall imbalance in globin synthesis (α:β) was the result of a deficiency in α chain production (Table 2). The ratio $\alpha^A/\beta^A+\beta^{KW}$ was in the range associated with silent α thalassaemia. Since the results have shown an absolute decrease in the amount of product from one β locus, however, it seems that she might

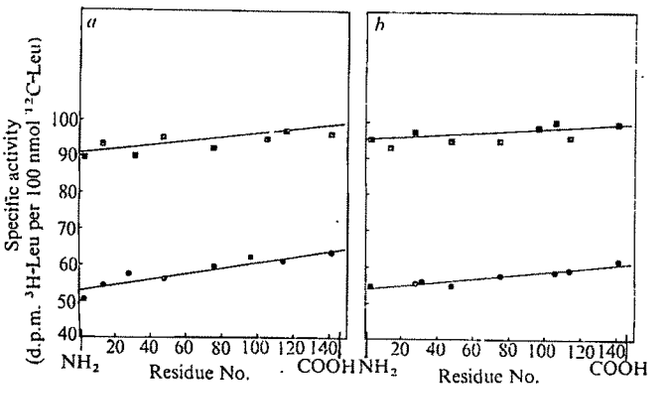

Fig. 3 Comparison of the rates of assembly of the β^{A} and β^{KW} chains. The gradient of radioactivity in the globin chains after 6 (●) and 9 (■) min incubation with ³H-leucine. The method used has been described previously[18]. *a*, $\beta^{K\ Woolwich}$ chain; *b*, β^{A} chain.

have a compensated α thalassaemia; α thalassaemia, β^{K+} thalassaemia. The haematological data for her son II-1 (Table 1) indicated that he has inherited the α thalassaemia gene but, as yet, he has not been available for *in vitro* biosynthetic studies. On diagnosing α thalassaemia, iron deficiency has to be considered. The serum iron levels in this family were all slightly low with a total serum iron binding capacity in the higher range of normal. As they were all similar, one would not expect this to lower the Hb A_2 in II-1 and not in the others; α thalassaemia in association with β thalassaemia has been described[10,11]. The results from the propositus are similar to those described in one family of Italian origin[10]. The amount of Hb KW in the cells of the propositus is lower than in either of her children, but it is recognised that an α thalassaemia can reduce the proportion of an associated β chain variant[4]. As the results of the *in vitro* biosynthetic studies do not implicate assembly or release of the completed chains as a possible point of interaction, it is difficult to understand at what other step in biosynthesis a deficiency of α chains could produce this effect, unless at the level of initiation.

Usually (though not invariably) β^{A} thalassaemia is associated with typical haematological features and these are not seen here. Of the important criteria of thalassaemia, the two found with Hb K Woolwich are the reduction of β-chain synthesis and raised Hb A_2.

Effect of ß-N-oxalyl-L-*a*, ß-diaminopropionic acid on glutamate uptake by synaptosomes

The unusual amino acid β-N-oxalyl-L-α,β-diaminopropionic acid (ODAP), isolated from the seeds of *Lathyrus sativus* is a potent neurotoxin[1–3]. It produces biochemical changes in the brain typical of an excitant amino acid and is implicated in the aetiology of human neurolathyrism caused by eating the seeds of *L. sativus*[4–6]. It may act as a glutamate antagonist: ODAP inhibits glutamate oxidation[7] possibly by inhibiting glutamate uptake in bovine brain mitochondria; it also acts as a competitive inhibitor of glutamate uptake in certain strains of yeast[8], and a similar process might occur at the synaptic level. Any effect of ODAP on glutamate uptake at synapses is significant in view of the neurotransmitter function of glutamate, which seems to be neuroexcitory as well as neurotoxic[9–12]. But Balcar and Johnston[13] have shown with rat brain slices that ODAP does not inhibit the glutamate uptake by the high affinity system.

The high affinity uptake of amino acids such as glutamate, aspartate, glycine and γ-aminobutyric acid by nervous tissue slices and homogenates reflects at least in part their accumulation by the nerve terminals[14–16]. We have studied the *in vitro* effect of ODAP on glutamate uptake by synaptosomes isolated from the brain of 12-day-old rats and from monkey spinal cord. We chose these tissues because ODAP produces convulsions in young rats when injected intraperitoneally and precipitates hind leg paralysis in monkeys when introduced into the cerebrospinal fluid through the lumbar route[1–3].

Synaptosomes were isolated from the whole brain of rats by the procedure of Eichberg *et al.*[17] except that the P2 pellet was isolated by centrifuging the P_1 supernatant at 7,000*g* for 30 min instead of at 10,000*g* for 1 h. This modification by Levitan *et al.*[18] results in a purer preparation of synaptosomes. Synaptosomes were isolated from the monkey spinal cord by the procedure described[19] for the guinea pig spinal cord. Two distinct synaptosomal bands, seen at 1.0–1.2 and 1.2–1.4 M sucrose after density gradient centrifugation in a SW25–1 rotor for 2 h, were collected. These synaptosomal fractions were diluted to 0.4 M and the pellet collected by centrifugation at 15,000*g* for 20 min. It was used for amino acid uptake studies, conducted essentially according to Peterson and Raghupathy[20] (Figs 1–3). The integrity of synaptosomes were ascertained by measuring the lactic dehydrogenase activity of the samples[21] and demonstrating that very little radioactivity

was retained on the filter when the samples after incubation were lysed with water before filtration.

Synaptosomes isolated from rat brain showed a typical biphasic uptake pattern for glutamate (Fig. 1). The low and high affinity uptake systems were characterised by K_m values of 5×10^{-3}M and 2.5×10^{-5}M respectively. We did not take into account glutamate in the synaptosomal preparation but the K_m values obtained were similar to those reported for glutamate uptake in rat and cat nervous tissues[14,15]. Addition of ODAP at 10^{-3}M concentration produced around 15–20% inhibition of glutamate uptake by the low as well as high affinity systems. The Lineweaver–Burk analysis of the data indicates a noncompetitive type of interaction (Fig. 1). The pattern remains essentially the same at ODAP concentration of 5×10^{-3}M or 10^{-4}M.

Monkey spinal cord synaptosomes also exhibited a biphasic pattern of glutamate uptake with K_m values of 1.2×10^{-5}M and 0.5×10^{-3} for the high and low affinity uptake systems respectively (Fig. 2). Similar results have been reported for rat and cat spinal cord slices and homogenates[14,15]. Addition of ODAP to the incubation medium showed a competitive inhibition of glutamate uptake by the high affinity uptake system. ODAP has practically no effect on the low affinity uptake of glutamate.

We examined the specificity of ODAP action by studying its effects on glycine uptake, since a high affinity uptake system for this amino acid has been shown to exist only in the spinal cord preparations but not in those of the cerebral cortex of rat and cat[14–16]. We found that a biphasic pattern for glycine uptake also exists in the monkey spinal cord synaptosomes, but ODAP has very little effect on either the low or high affinity uptake of glycine (Fig. 3).

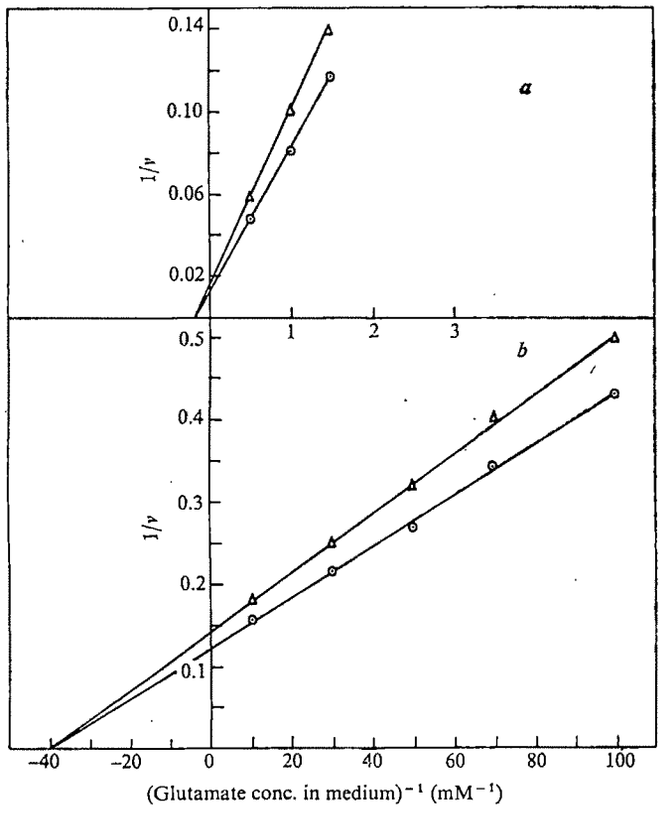

Fig. 1 Effect of ODAP on the uptake of glutamate by young rat brain synaptosomes. Synaptomes (200 μg protein ml^{-1}) were incubated with 0.25 μCi of μ-^{14}C L-glutamate (99 mCi mmol^{-1}) mixed with unlabelled L-glutamate to give the required concentration in a final volume of 1 ml. Incubation were carried out in 5 ml conical flasks at 37° C for 3 min in a Dubnoff shaker. The medium composition was: 10 mM Tris; 150 mM NaCl; 15 mM $MgCl_2$ adjusted to *p*H 7.4. Reactions were started by the addition of synaptosomes. All incubations were terminated by the addition of 2 ml of ice cold medium followed by quantitative transfer to and washing with 30 volumes of the same buffer over Millipore filters (0.45 μm HAWP). The dried filters were then counted in 10 ml of Cocktail (0.5% PPO (w/v) in Toluene) in a Beckman LS-100 scintillation counter. *v* is expressed as nmol glutamate taken up per mg protein per 3 min. *a*, Low affinity uptake; *b*, high affinity uptake; O—O, Control uptake; Δ—Δ, uptake in the presence of ODAP (10^{-3}M).

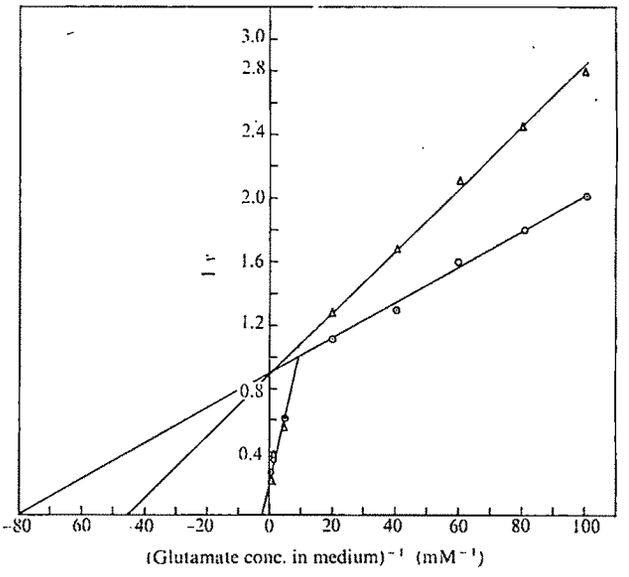

Fig. 2 Effect of ODAP on glutamate uptake by monkey spinal cord synaptosomes. Conditions of incubation as in Fig. 1. O—O, Control uptake; Δ—Δ, uptake in the presence of ODAP (10^{-3}M).

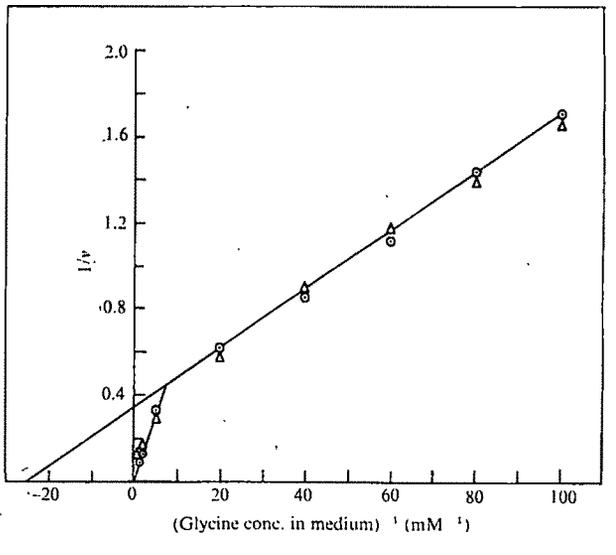

Fig. 3 Effect of ODAP on glycine uptake by monkey spinal cord synaptosomes. Conditions of incubations as for glutamate (Fig. 1) with the following modification. The medium had reduced NaCl (125 mM) but with additional KCl (25 mM). μCi of 2-^{14}C-glycine (27 mCi mmol^{-1}) was used in combination with unlabelled glycine to give the required concentrations in a final volume of 1 ml. *v* is expressed as nmol glycine taken up per mg protein per 3 min. O—O, Control uptake; Δ—Δ, uptake in the presence of ODAP (10^{-3}M).

ODAP does therefore inhibit glutamate uptake by synaptosomes isolated both from young rat brain and from monkey spinal cord. The lesser potency of ODAP and the type of interaction observed in the rat brain synaptosomes might be a species characteristic or could be due to the presence of a more heterogenous population of synaptosomes, with affinity uptake systems for transmitter amino acids different from the monkey spinal cord. The localisation of glutamic and aspartic acids in synaptosomes separable from synaptosomes storing other amino acids has been reported[22].

The high affinity uptake system of synaptosomes is recognised to be important for the removal of amino acid transmitter from the synaptic environment[14,15]. Inhibition of this uptake, even the 15–20% inhibitory effect of ODAP seen for the rat brain synaptosomes, could be significant because of the extremely low concentration of glutamate required to cause excitation[10]. It is also interesting that ODAP inhibits glutamate uptake but not glycine uptake in monkey spinal cord synaptosomes. Since glycine is an inhibitory transmitter at the spinal cord level, these results could mean that the effects of ODAP in causing convulsions in young rats and hind leg paralysis in monkeys are primarily neuroexcitory, and are possibly mediated by glutamate. We have observed similar results with regard to the uptake of L-aspartate (unpublished results). Furthermore, ODAP administered *in vivo* to young rats is localised in synaptosomes and can cause the release of excitory amino acids from synaptosome preparations (manuscript in preparation).

These studies were supported by the US National Institutes of Health. This paper is dedicated to the memory of Professor P. S. Sarma and Dr P. S. Cheema, Department of Biochemistry, Indian Institute of Science, Bangalore.

Quasi morphine-abstinence syndrome

ASSUMING that morphine induces dependence in response to continued interaction of the drug with an unidentified biochemical process of neurones, then suitable pharmacological manipulation might produce a paradigm of the morphine abstinence syndrome in experimental animals not exposed to any opiate. If so, the way in which such a quasi-abstinence syndrome was produced might throw light on the endogenous biochemical process involved[1].

In attempting to produce a quasi-abstinence syndrome, we used theophylline, naloxone and 5-hydroxytryptophan (5-HTP). Theophylline was used because it inhibits the phosphodiesterase of rat brain[2] and would therefore preserve brain cyclic nucleotides and because theophylline or cyclic 3′, 5′-adenosine monophosphate (cyclicAMP) intensifies morphine dependence in mice[3]. Naloxone was used because it has been shown to produce an abstinence-like effect in ileum isolated from naive guinea pigs[4]. 5-HTP was used because the ileum from morphine-treated guinea pigs responded more intensely to the product of its enzymatic decarboxylation, 5-hydroxytryptamine (5-HT), than did ileum from naive animals[5].

Male albino rats were treated orally with theophylline (100 mg kg^{-1}) in 20% w/v gum acacia or with the vehicle. At either 1 h or 1.75 h later, rats received 0.9% w/v NaCl in water (saline) subcutaneously or intraperitoneally, or 5-HTP (200 mg kg^{-1}) in saline intraperitoneally, according to the treatment schedule. Two hours after the first treatment with theophylline or vehicle, animals were challenged with a subcutaneous injection of either naloxone hydrochloride (10 mg kg^{-1}) in saline; saline; diamorphine hydrochloride (heroin) (1 mg kg^{-1}) in saline; or heroin (1 mg kg^{-1}) + naloxone hydrochloride (0.2 mg kg^{-1}) in saline. For 15 min after challenge the behavioural responses of the rats were recorded by observers who did not know what treatment each animal had received, as previously described[6]. Before each treatment and at the end of the observation period rats were weighed. For comparison, morphine dependence was induced with a single subcutaneous injection of a sustained-release emulsion containing 150 mg kg^{-1} morphine and abstinence effects were observed 24 h later after subcutaneous challenge with 1 mg kg^{-1} naloxone[6]. The incidence of responses was expressed as the presence or absence of a response in each animal observed. Weight changes were transformed into percentages and group comparisons were made using the Mann-Whitney U test. Comparable weight changes were not available for rats exposed for 24 h to the sustained-release morphine. For all other responses, probabilities were computed by means of the Fisher's exact probability test for a 2×2 contingency table. Weights of drugs are expressed as weights of active base.

Table 1 summarises the responses of rats to the various treatment schedules used. Comparison of responses to theophylline and vehicles with those to vehicles alone shows that theophylline significantly increased the incidence of eight responses — irritability to touch, diarrhoea, ptosis, body shakes, head-shakes, rearing, restlessness and weight loss. Naloxone alone increased the incidence of only two of these responses, irritability to touch and weight loss, as compared with controls receiving vehicles; but, after theophylline, naloxone produced a significantly higher incidence of four further responses (compared with theophylline alone), namely jumping, teeth chattering, irritability to handling and paw tremor and increased the significance of rearing and restlessness.

V, Vehicle corresponding with drug; N, naloxone, 10 mg kg^{-1} subcutaneously (s.c.); N^1, naloxone, 1 mg kg^{-1} s.c.;
T, theophylline, 100 mg kg^{-1} orally; HP, 5-hydroxytryptophan (5-HTP) 200 mg kg^{-1} intraperitoneally;
M, morphine, 150 mg kg^{-1} s.c. in a sustained-release preparation; NT, not tested.
After pretreatment with theophylline, or vehicle (2 h), saline (1 h) or 5-HTP or vehicle 15 min previously, rats were challenged with vehicle or naloxone. After pretreatment with morphine 24 h previously, rats were challenged with naloxone. Responses were recorded during 15 min after challenge. Letters a–h in the body of the Table indicate comparisons between columns where a significantly greater effect was found; where the letter is italic, $P < 0.01$, where it is not, $P < 0.05$.

5-HTP and vehicles, compared with vehicles alone, produced an increased incidence of three responses — irritability to touch, irritability to handling and diarrhoea, but reduced the incidence of rearing and restlessness. Theophylline, 5-HTP and vehicle gave a significantly increased incidence of irritability to touch, rearing, restlessness and weight loss compared with 5-HTP and vehicles. Treatment with theophylline, 5-HTP and naloxone gave a significantly increased incidence of six of the thirteen responses recorded compared with vehicles alone.

Table 1 also gives the abstinence effects observed in a similar way after withdrawal of morphine, precipitated with 1 mg kg^{-1} naloxone, 24 h after administration to rats of a sustained-release preparation of morphine. The incidence of many of the responses is still higher than after theophylline, 5-hydroxytryptophan and/or naloxone.

Table 2 Blockade by heroin of behavioural responses of rats to theophylline and removal of blockade by naloxone.

T, theophylline, 100 mg kg^{-1} given orally at 0 h; V, saline, 10 ml kg^{-1} given subcutaneously (s.c.) at 1 h; V^1, saline s.c. H, heroin, 1.0 mg kg^{-1} s.c. or H + N, heroin 1 mg kg^{-1} + naloxone, 0.2 mg kg^{-1} s.c. at 2 h. Other details as in Table 1.

Table 2 summarises experiments in which heroin (1 mg kg^{-1}) was tested as an inhibitor of responses induced by theophylline. Heroin largely suppressed the quasi-abstinence effects. Naloxone (0.2 mg kg^{-1}) was found to overcome this inhibition by heroin.

Of the various treatment schedules, theophylline with naloxone produced the closest resemblance to a true morphine abstinence syndrome (Table 1); but the presence of theophylline in any schedule led to a high incidence of several quasi-abstinence responses. 5-HTP produced some behavioural responses resembling those of abstinence, but these were fewer than with theophylline. The results of treating naive rats with theophylline resembled in four ways the abstinence syndrome during morphine withdrawal without precipitation by an antagonist: first, many of the same responses increased in incidence; second, naloxone increased the incidence of responses in both conditions; third, heroin lessened the incidence of responses; and fourth, naloxone antagonised this effect of heroin. We therefore apply the term 'quasi-abstinence syndrome' to the behavioural state produced in the naive rat by theophylline.

The ability of theophylline to produce quasi-abstinence effects indicates that cyclic nucleotides may be involved in morphine dependence. This accords with the findings that cyclic AMP or theophylline antagonised the antinociceptive effect of morphine in the rat[7,8] or mouse[8] and enhanced tolerance and dependence in the mouse[3], although other cyclic nucleotides were inactive. This observation is consistent with the suggestion[9] that the raised level of protein kinase found in rat brain after morphine withdrawal may contribute directly to the signs of abstinence.

The contribution of 5-HTP to the quasi-abstinence syndrome reinforces a comment made some years ago[10]. Also, it is consistent with the finding that the ileum isolated from morphine-tolerant guinea pig is more responsive to 5-HT than is normal ileum[5]. That 5-HT inhibits noradrenaline stimulation of adenyl cyclase[11], makes plausible an association between this effect of 5-HT and a cyclic AMP mechanism.

In vivo studies alone cannot determine the precise mechanism of action of a drug, but they can indicate where this mechanism should be sought. The present studies have indeed pointed to a further exploration of the interaction of morphine with cyclic nucleotides; and it has been reported that morphine potently antagonises the activation by PGE_1 or PGE_2 of cyclic AMP formation by rat brain or intestine homogenate[12]. It therefore seems possible that morphine tolerance and dependence may arise through compensatory changes in processes related to this PGE – cyclic AMP interaction.

We thank J. E. Czogala, N. J. Cuthbert, C. A. Dinneen and M. D. Hammond for help in observing animals, L. C. Dinneen for statistical help and Sankyo Limited for naloxone.

Neurotrophic control of colchicine effects on muscle?

COLCHICINE, a substance known to block axonal transport[1,2], has been reported to mimic the effects of denervation on mammalian skeletal muscles[3-5]. These effects, which include an increased extrajunctional sensitivity to acetylcholine (Ach) and a fall in resting membrane potential, occur a few days after colchicine is applied locally to the nerve in doses that do not seem to interfere with nerve impulse conduction, neuromuscular transmission, or muscle tension evoked by stimulation of the nerve[3-5]. It seems, therefore, that denervation-like changes may be induced in the presence of normal muscle activity and this suggestion is supported by experiments reported here in which the diaphragms of rats with apparently normal respiration became supersensitive to Ach after injection of colchicine into one of the legs (mean extrajunctional Ach sensitivity of 22 fibres from three rats was 4.6 mV nC^{-1}, range 0–30 mV nC^{-1}). It has been suggested that colchicine produces these changes in muscle by blocking some component of axonal transport, thus interfering with the neurotrophic control of muscle[3,4]. Colchicine also has a systemic effect[5], however, and its effect on muscle might be direct and occur independently of any of its effects on nerve. Here I examine this possibility.

The experiments were performed on young white rats each weighing about 200 g. The sciatic nerve was resected on one side, and two platinum stimulating electrodes were implanted in the denervated leg, one on each side of the soleus muscle. After waiting 1 d for neuromuscular transmission to fail and degeneration of motor nerve terminals to begin[6], the muscle was stimulated directly by intermittent trains of stimuli at 10 Hz until the acute experiment. Such stimulation largely prevents the development of Ach supersensitivity in denervated muscle[7]. Because colchicine is reported to have its greatest effect on muscle after 4 d (ref. 4), it was injected (3.5 µl of a 0.2 M solution) intramuscularly high in the thigh 4 d before the acute experiment. Fourteen days after denervation, the soleus muscles were removed from both sides and placed in a chamber superfused with oxygenated rat Ringer's solution at room temperature. Both the resting membrane potential and the sensitivity to electrophoretically applied Ach were examined in single muscle fibres by conventional techniques[8]. Control animals were similarly treated but received no colchicine; in some of these controls, the unstimulated soleus muscle was also denervated.

Four days after the injection of colchicine, the mean extrajunctional Ach sensitivity of fibres with intact innervation (61 fibres, six muscles) was 3.2 mV nC^{-1} (range 0.2–14.3 mV nC^{-1}) (Fig. 1*a*, open columns). A similar sensitivity and distribution

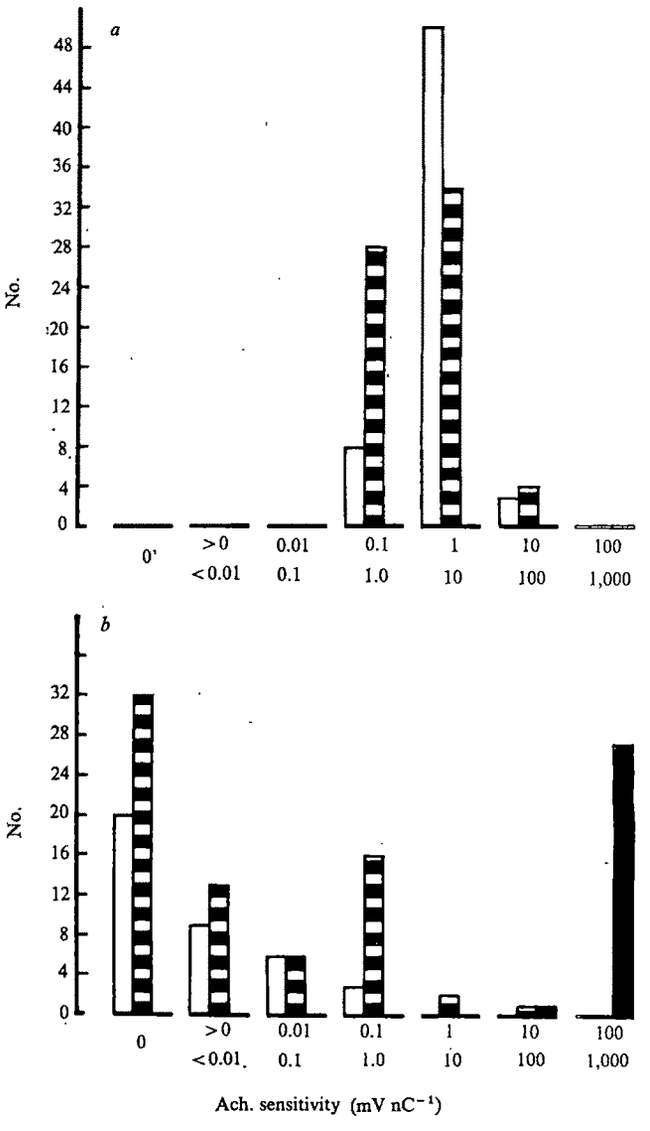

Fig. 1 Extrajunctional Ach sensitivity of soleus fibres from innervated (open columns), denervated stimulated (striped columns) and denervated muscles (solid columns). Denervation lasted 14 d. Stimulation took place from day 2 to day 14 after denervation. Ach sensitivity was measured *in vitro* at 2 mm from the myotendinous junction and is expressed as mV depolarisation per nC charge passed through a micropipette containing 3 M AchCl. Because the supersensitivity following either denervation or colchicine treatment is approximately equal along the membrane lying between the endplate and the myotendinous junction[5,9], these values may be taken as representative of the average extrajunctional sensitivity for the whole fibre. *a*, 270 µg Colchicine injected intramuscularly high in the thigh on day 10, that is 4 d before the Ach-sensitivity was tested; *b*, no colchicine was given.

about the mean (3.2 mV nC^{-1}, range 0.1–15.0 mV nC^{-1}, excluding one fibre with 57 mV nC^{-1}) was found in denervated stimulated soleus fibres (66 fibres) from the opposite leg of the same animals (Fig. 1*a*, striped columns). In the absence of colchicine the same stimulation largely blocked the supersensitivity of denervated fibres (70 fibres, five muscles) so the majority of these were insensitive or only very weakly sensitive (Fig. 1*b*, striped columns) and were indistinguishable from normal fibres (Fig. 1*b*, open columns). In two of the five denervated stimulated muscles, a few fibres had a higher sensitivity than normal. These fibres generally occurred in small groups clearly separated from the insensitive or weakly sensitive fibres in the same muscle. Their high sensitivity may, therefore, be caused by inadequate stimulation or local injurious effects of the stimulation[7]. In contrast, denervated but unstimulated fibres (27 fibres, three muscles) were all highly sensitive with a mean sensitivity of 250 mV nC^{-1} (range 50–525) (Fig. 1*b*, solid columns). It seems that colchicine raises the Ach sensitivity of both innervated and denervated stimulated fibres to about the same extent.

Colchicine had a comparable effect on resting membrane potential. Both innervated and denervated stimulated soleus fibres exposed to colchicine had similar relatively low mean resting membrane potentials; 67.4 ± 4.8 mV (mean ± s.d.) and 67.5 ± 4.2 mV (mean ± s.d.), respectively. In the absence of colchicine the corresponding values were higher: 70.9 ± 4.4 mV and 74.1 ± 4.9 mV. The lowest membrane potentials were recorded in fibres that were only denervated (61.6 ± 5.3 mV). The effect of colchicine on both resting membrane potential and Ach sensitivity was thus similar to that of denervation but less pronounced.

All innervated muscles exposed to colchicine twitched vigorously to stimulation of the nerve and miniature endplate potentials of approximately normal amplitude and frequency were observed in all fibres examined. In denervated stimulated muscles, there was no twitch to nerve stimulation, and no miniature endplate potentials were observed.

The increase in extrajunctional Ach sensitivity and fall in resting membrane potential induced by colchicine in innervated rat soleus muscles confirm other findings[3-5]. In addition my experiments show that similar changes developed in denervated muscles that were kept active by direct stimulation. As direct stimulation in the absence of colchicine has been shown to prevent such changes[7] it seems that colchicine has some effects on the muscle membrane that are not mediated by the nerve. These effects of colchicine on innervated muscle should therefore not be taken as evidence for the neurotrophic control of extrajunctional membrane properties. The mechanism behind the effect of colchicine on muscle is not known, and is in itself of some interest.

I thank Drs E. Frank and J. K. S. Jansen for discussion and comments on the manuscript.

Pseudorotation mechanism of ATP hydrolysis in muscle contraction

AN analysis of the reaction mechanism of ATP hydrolysis may elucidate how ATP provides energy for muscle contraction. Kinetic studies of the mechanism of ATP hydrolysis catalysed by myosin and its proteolytic subfragments[1,2], revealed at least two intermediates before the rate limiting step: (1) enzyme-bound ATP (M*ATP) and (2) an intermediate (M*ADP·P_i) that yields ADP and P_i when a quenching reagent such as $HClO_4$ is added. Trentham *et al.*[2] proposed that the rate limiting step is the transition from M*ADP·P_i to the Michaelis product complex M·ADP·P_i. That M*ADP·P_i is distinct from the Michaelis product complex is supported by observations made using techniques which include spin labelling[3], difference ultraviolet absorption spectroscopy[4], extrinsic probe fluorescence[5] and intrinsic myosin fluorescence[6]. Each method shows that the conformation of myosin *during* ATP hydrolysis differs from the conformation induced by the binding of ADP and P_i. This conclusion is supported further by the observation that the free energy change for the reversible reaction M*ATP $\rightleftharpoons$ M*ADP·P_i is only −1.3 kcalories per mol (ref. 7). Although comparable in energy with M*ATP, M*ADP·P_i nevertheless seems to be closely related to products because it decays to ADP and P_i when exposed to a quenching reagent. Although this decay to ADP and P_i has been widely interpreted as indicating that ATP is already cleaved in M*ADP·P_i, it could alternatively be interpreted in terms of an uncleaved but labile reaction intermediate.

In the intermediate $P_i \rightleftharpoons H_2O$ exchange[8] ^{18}O must be incorporated into either M*ATP or M*ADP·P_i. Sartorelli *et al.*[9] have shown that when myosin-catalysed ATP hydrolysis is quenched by $HClO_4$ containing $H_2{}^{18}O$, no ^{18}O is detected either in the P_i cleaved from ATP or in the myosin. This implies that H_2O must enter both the hydrolysis and the intermediate exchange reactions before the formation of M*ADP·P_i. Thus M*ADP·P_i cannot be some form of anhydride such as a phosphorylated myosin or metaphosphate.

We show here that a pseudorotation reaction mechanism for ATP hydrolysis can account for both the intermediate and medium[10] $P_i \rightleftharpoons H_2O$ exchanges as well as the characteristics of M*ADP·P_i. A pseudorotation mechanism has previously been proposed for ATP synthesis in mitochondrial oxidative phosphorylation[11–13]. We have recently shown it to be the only mechanism proposed so far that accounts adequately for the mitochondrial oxygen exchanges[14].

Figure 1 presents a schematic representation of the pseudorotation mechanism of ATP hydrolysis. The pseudorotation process transforms the P–O bond cleaved in hydrolysis from a relatively short, strong and nonreactive equatorial bond (Fig. 1*a*) to a relatively long, weak and reactive apical bond (Fig. 1*b*). In Fig. 1*a* the pair of oxoniums bound by H bonds to the enzyme and apical bonds to the phosphorus centre constitute two entry points for H_2O oxygen. The diagram shows that by dynamic reversal of the H_2O binding step before pseudorotation, the two oxygens in the pair of oxoniums could equilibrate with the H_2O oxygens of the medium. This equilibration could introduce up to two labelled oxygens into the P_i cleaved in ATP hydrolysis.

Under certain conditions, however, all four of the oxygens in the P_i cleaved in ATP hydrolysis can be labelled[14,15]. Since the enzyme-bound H_2O exchanges with the medium H_2O, some of the time a H_2O molecule must be missing from the active site. In the absence of H_2O the γ-phosphoryl of ATP might undergo a rotation about the bridge P–O bond in a time comparable with the H_2O exchange time. In this way all four of the oxygens in the P_i cleaved from ATP could be labelled with ^{18}O. It must be emphasised that such a rotation could occur only in the absence of the H_2O molecule. In the pentacoordinate intermediate A the γ-phosphoryl would presumably

be bound so tightly that no rotation could occur. One can also conceive of a mechanism in which complete labelling of P_i occurs into a tightly bound γ-phosphoryl of ATP. For such a mechanism the exchange illustrated in Fig. 1 would be only a prototype.

Since H_2O must enter both the hydrolysis and the intermediate exchange reactions before the formation of M*ADP·P_i, the only alternative to intermediate exchange occurring into M*ATP seems to be the following sequence of events: (1) cleavage of the P–O bond, (2) rotation of P_i in the active site, (3) spontaneous reformation of the P–O bond, and (4) exchange of enzyme-bound H_2O with medium H_2O. If all four of the oxygens of the cleaved P_i were able to interchange their positions in the active site, then all four of the P_i oxygens could be labelled by this mechanism. However, the weak binding implicit in the rotation of P_i in the active site seems to be inconsistent with the evidence that M*ADP·P_i is not a Michaelis product complex but rather is energetically comparable with M*ATP. This alternative therefore seems unlikely.

Thus it seems that exchange occurs directly into the γ-phosphoryl of M*ATP. Excluding an unlikely rotation of the ATP-H_2O adduct in the active site, direct exchange into M*ATP implies at least two entry points for H_2O oxygen. This exceedingly restrictive condition would exclude all mechanisms not of the type depicted in Fig. 1.

Concerning the medium exchange, there is a nucleotide requirement as a cofactor that can be satisfied by nucleotide mono-, di- and triphosphates as well as the ATP analogue adenylyl-methylenediphosphonate which does not undergo hydrolysis[16]. This implies that the medium exchange does not occur through the reversal of hydrolysis. Medium exchange must therefore occur directly into P_i which is analogous to the requirement that intermediate exchange must occur directly into the γ-phosphoryl of ATP by means of two or more entry points of H_2O oxygen. Thus consideration of the medium exchange independently leads to the same conclusion as that reached from consideration of the intermediate exchange.

A medium exchange separate from the reversal of hydrolysis is similar to the mitochondrial $P_i \leftrightharpoons H_2O$ exchange separate from the reversal of phosphorylation[14]. Since the characteristics of this mitochondrial $P_i \leftrightharpoons H_2O$ exchange can be rationalised by a mechanism stereochemically analogous to the mechanism proposed for the mitochondrial ATP $\leftrightharpoons H_2O$ exchange, we propose that the medium exchange can similarly be rationalised by a mechanism stereochemically analogous to the intermediate $P_i \leftrightharpoons H_2O$ exchange.

Equating intermediate *b* in Fig. 1 with M*ADP·P_i accounts for: (1) the difference between M*ADP·P_i and the Michaelis product complex, (2) the 'high energy' nature of M*ADP·P_i, (3) the breakdown of M*ADP·P_i to yield ADP and P_i when a quenching reagent is added, and (4) the breakdown of M*ADP·P_i without incorporation of ^{18}O into either P_i or myosin.

The mechanism proposed here for the intermediate $P_i \leftrightharpoons H_2O$ exchange is identical to that proposed for the mitochondrial ATP $\leftrightharpoons H_2O$ exchange[11] except that the ^{18}O appears in the P_i cleaved from ATP rather than in ATP itself. However, no myosin-catalysed ATP $\leftrightharpoons H_2O$ exchange has been detected[8,9]. The failure to detect a myosin ATP $\leftrightharpoons H_2O$ exchange is consistent with the low value for the dissociation rate of unhydrolysed ATP ($\leqslant 0.02\ s^{-1}$)[7,17] together with the small steady state concentration of the dissociating species M*ATP relative to M*ADP·P_i[7].

Available evidence strongly supports a pseudorotation mechanism of ATP hydrolysis. It is therefore interesting to inquire whether a rationale might be discernible for this mechanism in muscle contraction.

In the model of Lymn and Taylor[18] actin and myosin are not associated in the transition from M*ATP to M*ADP·P_i. This would require that this transition be an approximately energy conserving process, as recently confirmed by Bagshaw and Trentham[7]. As developed elsewhere with regard to ATP

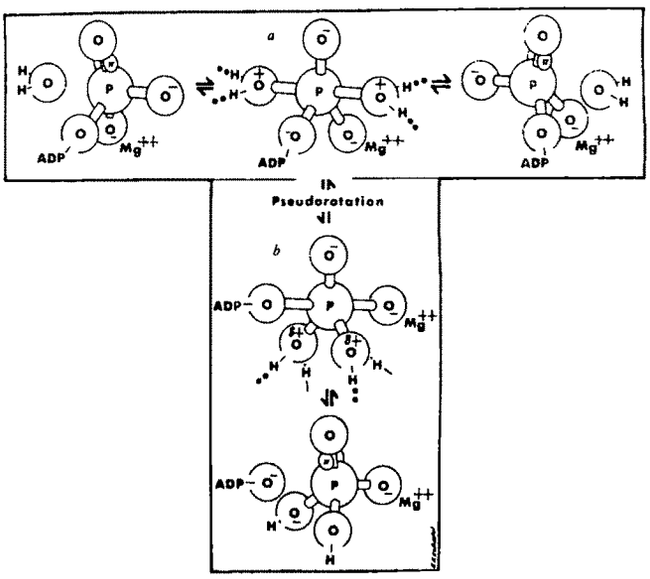

Fig. 1 Pseudorotation reaction mechanism of ATP hydrolysis. Reaction intermediate *a* with ADPO- equatorial has two apical oxoniums. Reaction intermediate *b* depicts ADPO- apical as required for cleavage from the phosphorus centre.

synthesis in oxidative phosphorylation, a fundamental aspect of the pseudorotation mechanism is the pair of oxoniums[11,12]. Its effect is to stabilise intermediate *a* in Fig. 1 relative to intermediate *b*, thereby providing approximate energy parity between the intermediate resembling reactants and the intermediate resembling products. Thus the pair of oxoniums responsible for a straightforward explanation of the oxygen exchanges could also account for the approximate energy parity between these two intermediates. This suggests a mechanistic basis for the correlation between intermediate exchange activity and muscle contraction noted by Yount and Koshland[15].

In the sliding filament model tension is generated by a change in orientation of the myosin head with respect to the actin filament[19]. This implies that actin must initially associate with myosin to give a state other than the thermodynamically most stable state of the actomyosin complex. It seems that actin associates initially with myosin in the M*ADP·P_i state[18,20]. As previously noted, there is considerable evidence that the conformation of myosin in the M*ADP·P_i state differs from that in the Michaelis product complex M·ADP·P_i. Thus these two conformations of myosin might be correlated tentatively with the two orientations of the actomyosin cross bridge invoked by Huxley and Simmonds[21,22] to explain the viscoelastic properties of active muscle fibres. This correlation would also be consistent with the requirement that, because the velocity of muscle contraction decreases with increasing load, the rate limiting step of ATP hydrolysis must be sensitive to tension. Exergonic bond cleavage would therefore occur in the mechanochemically coupled step since in this reaction mechanism cleavage occurs in the transition from M*ADP·P_i to M·ADP·P_i.

These considerations together with the dissociation of actomyosin induced by ATP binding[18] and the refractory state of myosin[20] indicate that the contraction cycle involves a sequence of discrete conformational states of myosin. A sequence of discrete conformational states of myosin as an ATPase enzyme requires a sequence of discrete reaction intermediates in ATP hydrolysis. The intrinsically step-wise character of the pseudorotation mechanism is well suited for providing such a sequence of reaction intermediates with appropriate energetic characteristics.

In view of the apparent similarity between the ATP reaction mechanisms in muscle contraction and oxidative phosphorylation, it is of interest to note that the myosin fragment S-1

appears to be evolutionarily related to the mitochondrial coupling factor F_1 (ref. 23).

In vivo enhancement of tyrosine hydroxylation in rat striatum by tetrahydrobiopterin

THE hydroxylation of tyrosine, the rate-limiting step in the biosynthesis of catecholamines *in vivo*[1], depends on various factors: the concentration of apoenzyme and of cofactor (5,6,7,8-tetrahydrobiopterin, BH_4), the availability of molecular oxygen[2-4] and the activity of the system reducing the oxidised pteridine (dihydropteridine reductase[5]). Calculations based on the rate of tyrosine hydroxylation *in vitro* and on the cofactor concentration in brain suggested that the latter might be limiting[6,7], although its concentration at the enzyme site is not known. Similar conclusions were reached in experiments with cultures of sympathetic chain of chicks in which addition of biopterin increased the catecholamine content[8]. But no evidence exists for a possible role of BH_4 as limiting factor of tyrosine hydroxylation *in vivo*. We describe here the *in vivo* effect of BH_4, the natural cofactor of tyrosine hydroxylase[9], on dopamine formation in rat striatum.

Male albino rats of Wistar origin (Füllinsdorf), 180-200 g, were injected with an aqueous solution of BH_4 into one lateral brain ventricle (30-1,000 μg in 10 μl through a chronically implanted cannula[10]) or intravenously (125 mg kg^{-1}). The solutions contained 1% ascorbic acid. At various time intervals after administration of BH_4 0.18 μg L-2, 3-^{3}H-tyrosine in 10 μl (specific activity) 10 Ci $mmol^{-1}$) were injected intraventricularly. Animals injected with ^{3}H-tyrosine after ascorbic acid served as controls. The rats were decapitated 15 min after ^{3}H-tyrosine injection, the corpora striata immediately dissected and homogenised in 0.4 M ice-cold perchloric acid (1:5 w/v) containing 0.3% ascorbic acid and 10 μg dopamine. The radioactive catechols were absorbed on alumina[11], eluted with 4 ml 0.3 N acetic acid and measured in a liquid scintillation counter. In some experiments the composition of the eluate was checked by paper chromatography (Whatman P81; isopropanol, 0.2 N ammonium acetate, *p*H 6.0, 1:2; 15 h). Dopamine was the main component besides traces of 3,4-dihydroxyphenylacetic acid. The values were corrected for recovery (75 ± 2.3%).

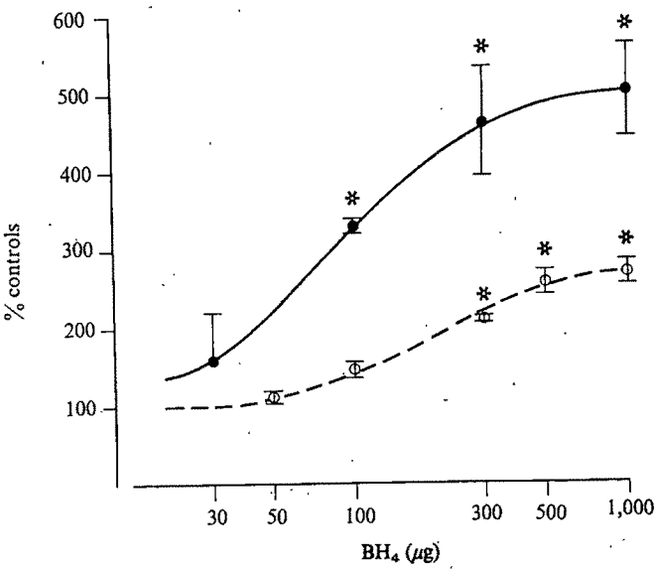

Fig. 1 Concentration of ●, tetrahydrobiopterin (BH_4), and ○, ^{3}H-catechols in the rat striatum following various doses of BH_4. BH_4 was administered into one lateral brain ventricle alone or immediately before 0.18 μg ^{3}H-tyrosine intraventricularly. Rats were killed 15 min after injection(s). The figures represent averages with s.e.m. of values from 12-36 determinations. Each determination was carried out with the corpora striata of one rat. Absolute control values: BH_4 24.5 ± 3.5nmol g^{-1}; ^{3}H-catechols 6.4 ± 0.8pmol g^{-1}. Significance against corresponding controls: $^*P<0.01$; all other values $P>0.05$.

For the measurement of the cofactor concentrations another group of rats received BH_4 (in 1% aqueous ascorbic acid) intraventricularly (i.v.) (see above) at various time intervals before killing. Animals injected with ascorbic acid alone served as controls. The corpora striata from one rat were homogenised in 0.2 M Na-phosphate buffer, *p*H 6.5 (1:5 w/v) containing 0.02 M ascorbic acid, heated for 90 s to 100° C and centrifuged. A 10 μl aliquot of the supernatant was incubated for 60 min at 30° C with: 0.2 M phosphate–citrate buffer, *p*H 6.4, 20 μl; 10 mM ascorbic acid, 20 μl; 0.5 mM L-*p*-^{3}H-phenylalanine (SA 40 mCi $mmol^{-1}$), 20 μl; 70 μg liver phenylalanine hydroxylase (purified according to Kaufman and Fisher[12], first two steps), dissolved in 20 μl 0.2 M Na-phosphate buffer (see above); water to a total volume of 130 μl[13]. Supernatant containing various concentrations of BH_4 (20-100 pmol in phosphate buffer) or phosphate buffer served as standards or blanks, respectively. The reaction was stopped by cooling to 0° C. After addition of 0.5 ml ice-cold Na-acetate buffer (0.2 M, *p*H 5.5), iodination

was performed using 1 mg N-iodosuccinimide[7] in 10 μl dimethylsulphoxide. After 5 min the samples were supplemented with 100 μl 30% trichloracetic acid, centrifuged and passed through columns of charcoal (Norit S×35)/Dowex 50W×4 (10/700 mg) (ref. 7). The effluent (combined with the washing, 1 ml water) containing tritiated water, was measured by liquid scintillation counting. In such a system the amount of tritiated water is proportional to the initial concentration of BH_4 in the incubation medium. In all experiments quenching was corrected by means of internal standards.

Intraventricular administration of increasing amounts (30-1,000 μg) of BH_4 alone and of BH_4 immediately before ^{3}H-tyrosine caused in the striatum a dose-dependent

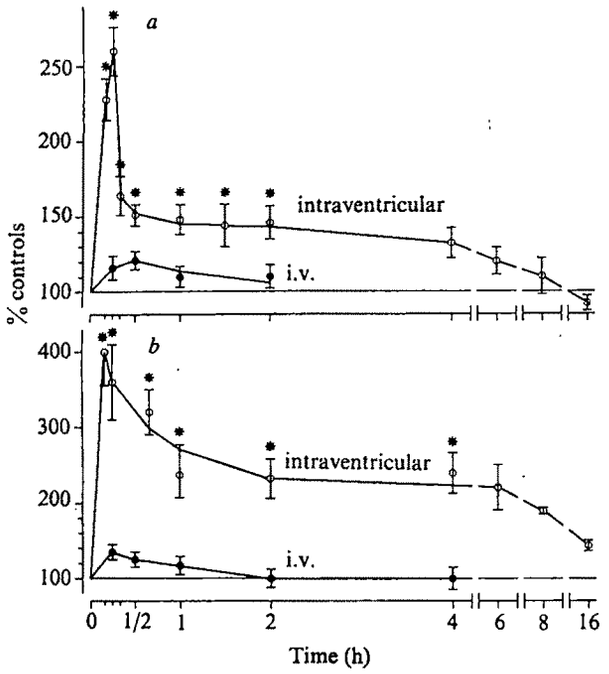

Fig. 2 Time course of *a*, ^{3}H-catechols and *b*, tetrahydrobiopterin (BH_4) in the striatum. BH_4 was administered into one lateral ventricle of the rat brain (0.5 mg per rat) or intravenously (125 mg kg^{-1}) alone or at various time intervals before intraventricular injection of 0.18 μg ^{3}H-tyrosine injected 15 min before killing. Abscissa: time between injection of BH_4 and decapitation. The figures represent means with s.e.m. of values from 12–36 determinations. Each determination was carried out with the corpora striata of one rat. Absolute control values: BH_4 29.0 ± 5.1 nmol g^{-1}; ^{3}H-catechols 7.5 ± 0.8 pmol g^{-1}. Significance against corresponding controls: $*P<0.01$; all other values $P>0.05$.

accumulation of the cofactor and an increased accumulation of labelled catechols, respectively (Fig. 1). The time course of accumulation of striatal BH_4 and increased accumulation of ^{3}H-catechols was similar. Maximal values were found 10 and 15 min respectively, after injection of the cofactor. After 4 h the ^{3}H-catechols had almost reached control levels again, whereas BH_4 was still somewhat increased at 16 h (Fig. 2), possibly due to a continuous recycling of the oxidised cofactor.

Intravenous administration of a large dose (125 mg kg^{-1}) of BH_4 alone or immediately before intraventricular injection of ^{3}H-tyrosine caused a small increase of the cofactor and of the ^{3}H-catechol content in the striatum respectively, which did not, however, reach a significant level (Fig. 2). This small effect may be due to poor penetration of the cofactor into the brain.

The enhanced accumulation of labelled catechols in the striatum which paralleled the increased BH_4 content was probably the consequence of an increased synthesis of the amines from ^{3}H-tyrosine. Thus, 250 mg kg^{-1} α-methyl-*p*-tyrosine (an inhibitor of tyrosine hydroxylase) i.p. 1 h before ^{3}H-tyrosine diminished both the formation of labelled catechols and their enhanced accumulation due to BH_4 (Fig. 3). An impaired elimination of the labelled catechols from the brain is unlikely since in preliminary experiments BH_4 did not enhance the accumulation of ^{3}H-catechols in the striatum of animals administered L-2,5,6-^{3}H-dihydroxyphenylalanine intraventricularly. This result also confirms that BH_4 acts at the level of the hydroxylation of tyrosine.

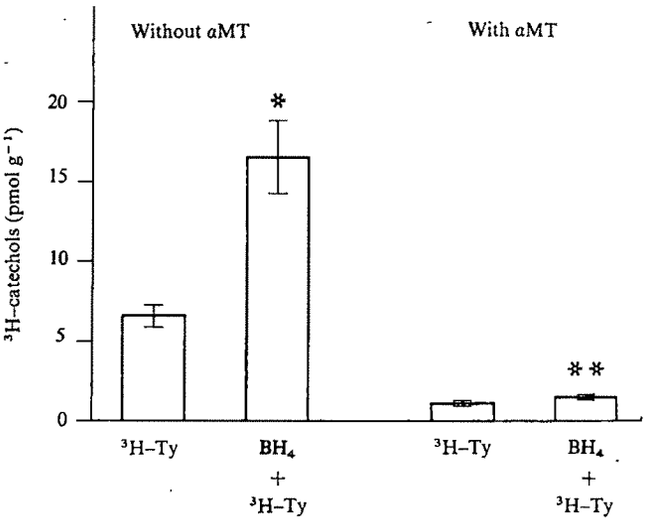

Fig. 3 Effect of α-methyl-*p*-tyrosine (αMT) on the increase of ^{3}H-catechols in rat striatum induced by ^{3}H-tyrosine (^{3}H-Ty) alone or in combination with tetrahydrobiopterin (BH_4). BH_4 (0.5 mg per rat) was injected into one lateral brain ventricle immediately before intraventricular administration of 0.18 μg ^{3}H-Ty. αMT (250 mg kg^{-1}) was administered i.p. 1 h before ^{3}H-Ty. Rats were killed 15 min after ^{3}H-Ty. The figures represent averages with s.e.m. of 4-6 determinations, each carried out with the corpora striata of one rat. Significance compared with corresponding values with ^{3}H-Ty alone: $*P<0.01$; $**P>0.1$.

The striatal content of endogenous dopamine and its major metabolite homovanillic acid (both measured fluorimetrically[11,14]) was not significantly changed 15 min after intraventricular injection of 500 μg BH_4 (dopamine: controls 8.7 ± 0.4, BH_4-treated 9.1 ± 0.2 μg g^{-1}, $P > 0.05$; homovanillic acid: controls 0.84 ± 0.07, BH_4-treated 0.80 ± 0.08 μg g^{-1}, $P > 0.05$; 12 animals per group). These findings indicate that of the total dopamine stored the newly formed amine is only a minor part which may have entered into the small (functional) pool previously claimed to be preferentially filled with the newly synthesised catecholamines[15].

From these results it can be concluded that in the striatum the amount of the apoenzyme of tyrosine hydroxylase is probably not the limiting factor for the hydroxylation of tyrosine *in vivo*. Under physiological conditions, tyrosine hydroxylase apparently does not work to its full capacity due to the limited concentration of BH_4. It is therefore possible that rapid changes in activity of tyrosine hydroxylase may be connected with modifications in the availability of reduced pteridine cofactor at the enzyme site.

The BH_4 was synthesised by Dr K. J. M. Andrews, Roche Products Limited, Welwyn Garden City, UK.

Increased myocardial cathepsin D activity during regression of thyrotoxic cardiac hypertrophy

SEVERAL types of hormonal or mechanical stimuli may cause cardiac hypertrophy. In many instances, when the stimulus is removed the heart rapidly regresses toward its original size. The cellular mechanism(s) by which this net cardiac catabolism and reduction of myocardial protein mass might be mediated have not been defined. One possibility might be an increase in the activity of intracellular proteolytic enzymes; accordingly, we have investigated the activity of cathepsin D, a lysosomal enzyme that is the major acid proteinase in the heart.

Our experimental model was the hypertrophied heart of the thyrotoxic rat. Exogenous administration of excessive doses of thyroid hormone is well known to lead to marked cardiac enlargement in the rat, and discontinuation of thyroid treatment results in a rapid return of heart weight to normal[1–4]. Indeed, during the first week of recovery from thyrotoxicosis, the heart loses 10% or more of its mass, in comparison with a weekly increase of 10% or more in normal rats[4].

Two-month-old male albino rats were divided into four matched groups. The first group ('control') was untreated for 6 weeks. The second group ('thyrotoxic') received no treatment for 3 weeks followed by daily injections of *l*-thyroxine (1.0 mg kg^{-1} intraperitoneally) for 3 weeks. The third group ('1-week recovery') received a similar 3-week course of thyroxine injections between the second and fifth week of the 6-week experimental period, and the last group was treated during the first 3 weeks only and then remained untreated for 3 weeks ('3-week recovery'). All the animals were killed on the same day by cardiac excision after being stunned by a blow to the head. Total body weights and the weights of the isolated cardiac ventricles were determined. A section of left ventricular muscle was excised immediately, diluted in a solution of 0.1% Triton at 4° C, minced and homogenised vigorously with a Willems homogeniser to disrupt maximally the cells and their organelles. The mixture was spun at 350*g* for 5 min to remove cellular debris, and the supernatant, which contained more than 90% of the total activity of the various enzymes tested, was taken for assay. Activities were measured for the lysosomal enzymes cathepsin D, β-acetylglucosaminidase and acid phosphates[5,6]. The activity of creatine phosphokinase[7], a nonlysosomal enzyme that serves as a good general marker of myocellular viability, was also measured, as was the protein concentration[8].

As others have described, thyroxine therapy caused marked cardiac hypertrophy in the rats. The ratio of ventricular weight to body weight was 0.36±0.01% (s.e.m.) in the control group compared with 0.56±0.02% in the thyrotoxic rats. The difference was due to a significant ($P<0.01$) increase in ventricular weight as well as a decrease in body weight in the treated animals. One week after cessation of therapy, heart weight was significantly reduced and body weight was increased (ratio=0.43±0.02%), and by 3 weeks all values had returned to normal (ratio=0.38±0.02%).

These changes in thyroid state and heart size were accompanied by significant alterations in the cardiac activity of cathepsin D. With thyrotoxic hypertrophy there occurred a 15% decrease in the mean activity of the enzyme, from 68.7 to 58.4 μg tyrosine h^{-1} mg^{-1} protein ($P<0.01$). Subsequently, with discontinuation of thyroid treatment and rapid regression of cardiac hypertrophy, the activity of the enzyme increased by 40% (Table 1) within 1 week. By 3 weeks, when the hearts had already returned to normal size, the activity of cathepsin D was also back to normal (71.3 μg tyrosine h^{-1} mg^{-1} protein).

During the rapid regression of hypertrophy, the increase in catheptic activity greatly exceeded the simultaneous decreases in heart weight and protein content (Table 1). Thus, the measured increase could not have been simply a consequence of slower net breakdown of the cathepsin D molecule compared with other cardiac proteins, which during generalised cardiac catabolism might lead to a relative elevation of the enzyme without an actual increase in its net production. Rather, the data indicate that there was an absolute increase in total cathepsin D activity in each heart, not due to generalised stimulation of all lysosomal enzymes. As Table 1 shows, there were no changes in the activities of glucosaminidase or acid phosphatase. Similarly, the nonlysosomal enzyme creatine phosphokinase was unaffected.

In separate tests, the tissue was homogenised gently in 0.25 M KCl to preserve intact lysosomes as far as possible[9,10];

Table 1 Comparison of ventricular weight, protein, and enzyme activities.

	Thyrotoxic	1-week recovery
Body weight (g)	299±7.6 (s.e.m.)	339±6.5*
Ventricular weight (g)	1.66±0.040	1.43±0.024*
Ventricular protein concentration (mg g^{-1})	102±1.4	102±2.0†
Creatine phosphokinase activity (μmol ATP per min per mg protein)	4.71±0.145	4.92±0.128†
β-acetylglucosaminidase activity (nmol nitrophenol per h per mg protein)	140±3.0	138±3.1†
Acid phosphatase activity (nmol nitrophenol per h per mg protein)	167±5.3	178±5.5†
Cathepsin D activity (μg tyrosine per h per mg protein)	58.4±1.05	81.5±1.77*
Nonsedimentable (free) cathepsin D activity (% of combined free + particulate-bound activity)	30±0.9	35±1.4*

Measurements were made on hypertrophied hearts of 16 thyrotoxic rats and 16 hearts that were undergoing rapid regression of hypertrophy 1 week after discontinuation of thyroxine injections.
* $P<0.01$ compared with thyrotoxic hearts.
† $P>0.10$ compared with thyrotoxic hearts.

subsequent assays revealed altered catheptic activity in the 'free' or nonsedimentable fraction of the cell (which is thought by some to reflect enzyme that is more accessible to intracellular substrates *in vivo*) as well as in the total homogenate (Table 1).

These findings are reminiscent of other instances in which an organ responds to withdrawal of the appropriate hormone by an increase in the activity of lysosomal enzymes and catabolism and atrophy of the tissue[11,12]. Of special interest is the regression of uterine smooth muscle after termination of pregnancy. Removal of the stimulus for uterine growth that is provided by sex hormones leads to rapid regression of the organ, and this is associated with an increase in the activity of uterine cathepsin D[12]. In this condition there are parallel increases in other lysosomal enzymes, although in some other tissues pharmacological or hormonal changes cause specific alterations in cathepsin D without generalised effects on all lysosomal enzymes[12,13].

Our experiments demonstrate that acute changes in the thyroid state are accompanied by specific alterations in the activity of cathepsin D in the heart. Although no cause-and-effect relationship can be established definitively from our data, it seems reasonable to speculate that the observed changes in proteolytic activity are involved in the mediation of the corresponding shifts in protein balance. These findings provide for the first time evidence of an enzymatic alteration that might link an external stimulus for the regression of preexistent hypertrophy to subsequent myocellular catabolism. Whether similar changes accompany regression from other varieties of cardiac hypertrophy remains to be determined.

Vasopressin release from the isolated neurohypophysis induced by a calcium ionophore, X-537A

TEN years ago observations on isolated neurohypophyses prompted the suggestion that action potentials in the hypothalamo-neurohypophysial tract release neurohypophysial hormones by promoting calcium influx and that the appearance of free calcium ions somewhere in the neurosecretory terminals provides the immediate stimulus for hormone extrusion[1-3]. Some time later it was argued that the role of calcium ions in stimulus-secretion coupling in this system and in many other secretory cells was to set in motion a common secretory mechanism, exocytosis[4]. Very recently the evidence supporting this view has been strengthened by light microscopic observations showing extrusion of secretory granules from mast cells on intracellular injection of calcium ions[5]. Meanwhile, electron microscopic[6-11] and chemical[12-16] evidence has borne out the conjecture that neurohypophysial hormones are secreted by exocytosis, and the case for calcium-influx as the initiating event has been strengthened by a number of observations set out in recent reviews[15,16]. These reviews make the further point that the neurohypophysis may be a useful model system for studying stimulus-secretion coupling in nerve cells generally: the involvement of calcium in release of neural transmitters is well-known and may have a similar explanation[17,18].

With the discovery of calcium ionophores a new tool has become available, and our purpose here is to report the stimu-

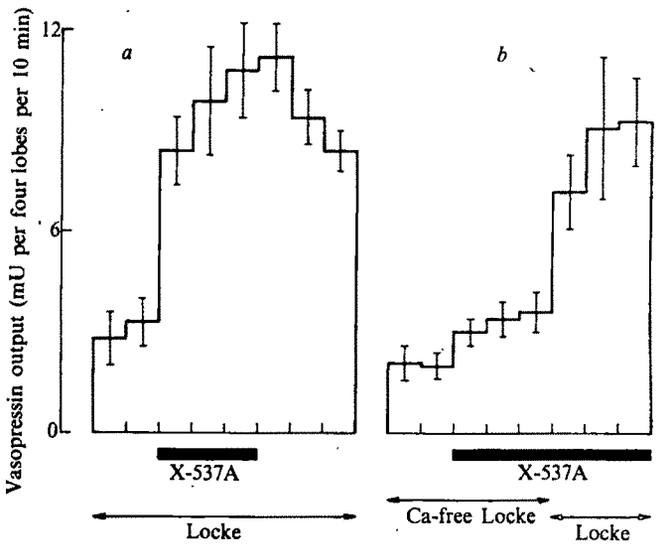

Fig. 1 Stimulant effect of the ionophore X-537A on output of vasopressin from rat neurohypophyses *in vitro* and the inhibitory effect of calcium deprivation. The methods for isolating neurohypophyses, incubating them, and measuring vasopressin output followed the original description[2] except that four neural lobes from male rats weighing about 250 g were used in each experiment and were impaled, after halving, on a fine platinum wire holder[29] facilitating transfer from one incubation chamber to the next. Media containing X-537A were prepared from a stock solution of the drug in dimethylsulphoxide. The final concentration of the solvent never exceeded 0.2% which is without effect on basal or stimulus-evoked output of vasopressin[30]. Drug and solvent did not interfere with the rat blood pressure method used for bioassay of vasopressin. Each of the two curves (*a*) and (*b*) shows vasopressin outputs (means ± s.e.) in successive 10 min incubation periods in three experiments. X-537A (6 $\mu g.ml^{-1}$) was present during the periods indicated by the heavy horizontal bars. Horizontal arrows indicate the incubation medium. Locke's solution contained (mM): NaCl, 150; KCl, 6.0; $CaCl_2$, 2.0; $MgCl_2$, 1.0; $NaHCO_3$, 10; glucose, 10. It was equilibrated with 5% CO_2 in O_2. In calcium-free Locke, $CaCl_2$ was omitted. Records begin after 40 min preincubation with Locke's solution (*a*) or calcium-free Locke's solution (*b*).

Table 1 Effect of calcium deprivation, with or without EDTA, on output of vasopressin in response to X-537A (25 μg ml^{-1})

Preincubation	(*A*) Locke (30 min)	(*B*) Ca-free Locke (60 min)	(*C*) Ca-free Locke + 2 mM EDTA (60 min)	(*D*) Ca-free Locke + 2 mM EDTA (70 min) followed by Mg-free Locke (60 min)
Incubation medium	Locke	Ca-free Locke	Ca-free Locke	Mg-free Locke
Vasopressin output (mU per four lobes per 10 min: mean ± s.e.m. (n))				
Before X-537A	2.0 ± 0.3(5)	2.1 ± 0.3(4)	2.7 ± 0.2(4)	2.2 ± 0.4(4)
During X-537A*				
0–10 min	9.1 ± 1.5(5)	4.8 ± 0.8(4)	3.6 ± 0.4(4)	4.7 ± 0.5(4)
10–20 min	13.5 ± 1.7(5)	4.9 ± 0.6(4)	3.8 ± 0.4(4)	6.8 ± 0.6(4)
20–30 min	16.7 ± 2.3(4)	4.9 ± 0.6(4)	3.8 ± 0.1(3)	8.5 ± 1.2(4)

* All outputs (columns *A*–*D* at each 10 min interval) are significantly higher ($P < 0.05$) than the corresponding values before X-537A.

lant effects, on neurohypophysial secretion, of one of these, X-537A. Like other calcium ionophores, X-537A is a substance that forms a reversible complex with calcium which, by its lipophilic nature, serves as a mobile calcium carrier that will transport calcium ions across biological membranes[19]. It is known to release histamine[20] and, more relevant to the work reported here, to elicit extrusion of secretory granules from mast cells by calcium-dependent exocytosis[21,22].

The methods we have used for studying release of vasopressin from isolated rat neurohypophyses have been described elsewhere (see legend to Fig. 1). In a concentration of 6 μg ml^{-1}, X-537A increased vasopressin output about three-fold in preparations incubated in a conventional, calcium-containing, Locke's solution. The effect outlasted exposure to the drug (Fig. 1*a*). By contrast, this ionophore had little stimulant effect on preparations incubated in calcium-free Locke, although vasopressin output rose substantially when calcium was reintroduced (Fig. 1*b*). This stimulant effect of calcium was clearly attributable to some priming effect of X-537A because calcium had no detectable effect on vasopressin output in each of four experiments where it was reintroduced after the same period of calcium deprivation without exposure to the ionophore, a finding in agreement with earlier observations[2].

In a concentration of 25 μg ml^{-1}, X-537A evoked a still greater output of vasopressin; the response in the presence of calcium (Table 1*A*) being approximately equal to that yielded by a maximally effective concentration (60 mM) of potassium[2]. Omission of calcium (with or without addition of EDTA) inhibited the response (Table 1*B* and *C*). This inhibitory effect was reversed, at least in part, by reintroducing calcium without magnesium (Table 1*D*.)

From these results it is evident that X-537A can stimulate vasopressin output through some calcium-dependent process. The most obvious explanation is that the drug acts on the neurohypophysial terminals as a calcium ionophore, and allows calcium to penetrate these terminals and initiate secretion in line with the original calcium influx hypothesis[1]. But at least one alternative, or additional, explanation deserves consideration, namely that X-537A owes its effect on vasopressin release to its additional ability to complex with and transport monovalent cations[19]. By such an action the drug might depolarise the neurosecretory terminals and set in motion the familiar potential-dependent calcium influx mechanism[3,23].

Further experiment revealed an additional stimulant effect of X-537A on vasopressin output which is not readily explained in terms of depolarisation or calcium entry. Thus, in a concentration of 50 μg ml^{-1} the drug increased vasopressin output from neurohypophyses exposed to a depolarising[2] concentration (60 mM) of potassium in a calcium-free medium (Fig. 2). The response was about half that subsequently obtained in the same preparations 10–20 min after introducing 2 mM calcium in the presence of 60 mM potassium which, as noted above, is the most effective concentration of potassium for evoking vasopressin secretion[2]. In the light of evidence that X-537A can release calcium from sarcoplasmic reticulum[24–26], we suggest that this stimulant effect on output of neurohypophysial hormone may result from mobilisation of cellular calcium and consequent elevation of the concentration of free calcium ions in the neurosecretory terminals. This would be in line with the original suggestion that the appearance of an excess of free calcium ions somewhere in the terminals provides the signal for release of neurohypophysial hormones[1].

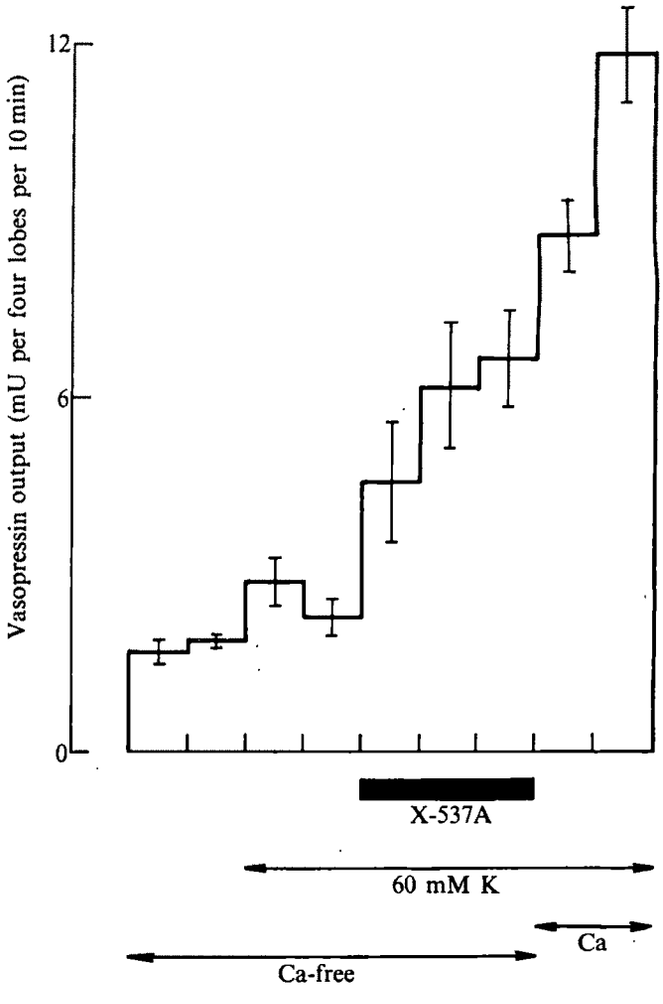

Fig. 2 Stimulant effect of the ionophore X-537A (50 μg ml^{-1}) on vasopressin output from neurohypophyses incubated in calcium-free Locke containing a depolarising[2] concentration of potassium. The record represents the mean (± s.e.m.) of four experiments and begins with lobes in calcium-free Locke (Ca-free) after 40 min preincubation in this same medium. After the first two periods shown, incubation was continued with calcium-free Locke with the potassium concentration raised to 60 mM (' 60 mM K '), the sodium concentration being lowered correspondingly to maintain tonicity[2]. X-537A was present during the period indicated by the heavy horizontal bar. After exposure to the drug, incubation was continued with 60 mM K Locke with the addition of 2 mM calcium (Ca). The secretory response obtained on adding calcium is near maximal for such preparations[2].

Conjecture along these lines is interesting because little is known of the physiological mechanisms for binding or sequestering calcium in secretory systems; yet some such mechanism must exist, as in muscle, if calcium is to function as a mediator in stimulus-secretion coupling. It is conceivable that responses to ionophores obtained from secretory preparations in calcium-free environments may provide a clue. It is possible however that X-537A, especially in the higher concentrations, may be able to release vasopressin independently of cellular as well as extracellular calcium: there are indications that acetylcholine can be released from nerves without involvement of calcium—for example, by high concentrations of ethanol[31].

In contrast to X-537A we have found, in similar experiments on six batches of neurohypophyses, that the calcium ionophore A-23187, in a concentration of 1, 2, 5 or 50 μg ml^{-1}, caused no obvious increase in vasopressin output. Since A-23187 differs from X-537A in having relatively little affinity for monovalent cations[19] this could be interpreted as support for the view that the response to X-537A involves depolarisation as well as calcium. Alternatively, A-23187 may for some reason, fail to act as an effective calcium ionophore in the neurohypophysial preparation as we have studied it. In any event, the behaviour of the neurohypophysis is quite different from that of mast cells studied in this laboratory where A-23187 (2–3 μg ml^{-1}) as well as X-537A causes a prompt release of secretory granules by exocytosis[21,22]. It is thus evident that different secretory cells vary in responsiveness to different ionophores as they do to various other stimuli[16]. Discussion of the possible physiological significance of this difference is best deferred until evidence from various other secretory preparations has been presented. These initial results encourage us to believe, however, that calcium ionophores may be useful new tools for the study of stimulus-secretion coupling in nervous tissue. We would add only, with regard to the exocytosis hypothesis of release of neurohypophysial hormones, that a stimulant effect of calcium after priming with X-537A, such as we have described for the neurohypophysis (Fig. 1*b*), has also been observed in mast cells where light and electron microscopy has shown the response to be extrusion of secretory granules by exocytosis[21,22].

We thank Drs Melville W. Osborne of Hoffman-La Roche, Inc. and Robert L. Hamill of Eli Lilly and Co. for X-537A and A-23187, respectively. This work was supported by grants from the US Public Health Service.

Capillary permeability and sympathetic activity in canine subcutaneous adipose tissue

Previous studies on the exchange properties of the microvasculature of canine subcutaneous adipose tissue have shown that electrical stimulation of the sympathetic nerves with frequencies within the physiological range, induced vasoconstriction accompanied by an increase in the transcapillary hydrodynamic conductivity expressed by the capillary filtration coefficient (CFC) (ref. 1). Given that CFC is a function of the product of the surface area available for exchange and the permeability of the capillary wall[2,3], these two factors must be separated to establish the functional properties of this vascular reaction. In attempting to do this, the clearance of locally injected $Na^{125}I$ was measured at constant flow perfusion, and was found to be significantly reduced during sympathetic stimulation. Similarly the permeability-surface area product (PS) of the vascular bed measured by the extraction of ^{86}Rb in subcutaneous adipose tissue decreased as a function of sympathetic stimulation (ref. 4 and J. Gainer, B. Linde, and S.R., unpublished).

These data suggest that sympathetic stimulation causes a constriction of the precapillary vessels resulting in a diminished number of capillaries open to blood flow. The increase of CFC could then be a consequence of either an overall increase in permeability of the capillary membrane, or a drastic alteration of the capillary pressure profile, which would enhance the effect of the more permeable venous segments of the microvasculature[5].

The present study was undertaken with the idea that a higher capillary permeability might affect the isovolumetric capillary pressure (P_{oi}) provided that the permeability change is of such a nature that osmotically active molecules become diffusible across the capillary membrane that is, the osmotic reflection coefficient for plasma proteins becomes smaller than one[6].

To test this hypothesis, experiments were performed on 13 female, mongrel dogs, anaesthetised with sodium pentothal

(30 mg kg^{-1}). The inguinal subcutaneous adipose tissue, located between the pubis and mammary glands, was prepared on the right side and placed in a plethysmograph with the artery, vein and nerve passing through a closely fitted opening[1,7]. After the administration of heparin, the artery supplying the adipose tissue was cannulated with plastic tubing and a silicone filled drop recorder was inserted. The plethysmograph was filled with Tyrode's solution kept at 38° C and connected to a volume recorder. Volume changes could be determined with an accuracy of ±0.05 ml. Blood pressures were monitored from the artery and vein supplying the adipose tissue by means of Statham pressure transducers and recorded on a Grass polygraph, together with the blood flow and tissue volume. The vein draining the tissue was cannulated with a widebore plastic tubing, the free end of which could be placed at any desired level above the preparation. In this way the venous outflow pressure, and therefore the venous and capillary pressures in the adipose tissue, could be varied. The isovolumetric capillary pressure (P_{ci}) was determined according to the principle of Pappenheimer and Soto-Rivera[8]. The blood flow was reduced in a stepwise fashion by means of a screw clamp on the artery. The level of the venous cannula was then adjusted to give a hydrostatic capillary pressure which rendered the adipose tissue isovolumetric. The values of arterial and venous pressures at isovolumetric states were then plotted (Fig. 1) and P_{ci} was estimated by extrapolating to zero pressure difference.

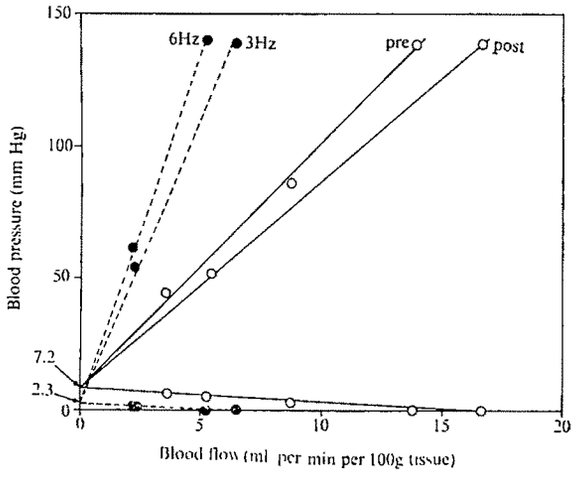

Fig. 1 Determination of isovolumetric pressure in canine subcutaneous adipose tissue. The points indicate arterial or venous pressures at different levels of blood flow at isovolumetric states. O, Determinations made during resting conditions (control), pre- and post-stimulation respectively; ●, determinations make during electrical stimulation of sympathetic nerves with 3 and 6 Hz, respectively. The data are extrapolated linearly to zero pressure difference, which coincides with zero blood flow. P_{ci} is indicated by the intercept on the ordinate. Colloid osmotic pressure 180 mm Hg.

In all experiments the extrapolated arterio-venous zero pressure difference was found to coincide with zero blood flow, as shown in Fig. 1. At zero flow there is no pressure drop along the blood vessels and, consequently, P_{ci} is equal to the pressure at the intercept of the extrapolated pressure-flow relations on the ordinate. The linear relationship between isovolumetric blood flow and isovolumetric arterial and venous pressures, respectively, is evidently a consequnce of the lack of autoregulatory responses in subcutaneous adipose tissue. Therefore, this method can be used with some precision to determine P_{ci} in subcutaneous adipose tissue.

The mean resting isovolumetric capillary pressure was 10.1 mm Hg (range 20.8–3.8, $n=13$), which was found to be lower than the plasma colloid osmotic pressure, 17.6 mm Hg (range 18.3–15.6). (The plasma colloid osmotic pressure was determined by means of a Hansen type osmometer utilised in conjunction with a membrane whose reflection coefficient for albumin was one.) Thus, the hydrostatic pressure which counterbalances all pressures tending to cause fluid absorption at an isovolumetric state is consistently lower than the plasma colloid osmotic pressure by an average of 7.6 mm Hg. This finding may be accounted for by a tissue osmotic pressure of 5–8 mm Hg which corresponds to a tissue protein concentration of 2–3%. This was shown to exist by direct micro-sampling in subcutaneous connective tissue[9], and by measuring the distribution of tagged albumin[10].

Following sympathetic nerve stimulation (3–9 Hz; 2 ms; 7–10 V), which was adjusted to diminish the blood flow to approximately one half, there was a marked reduction of P_{ci} which averaged 5.6 mm Hg (range 10.8–0; $P<0.001$) (Fig. 1). As in the case of resting conditions, in every experiment it was possible to determine P_{ci} by linear extrapolation to zero flow. P_{ci} is estimated by gradually decreasing the arterio-venous pressure difference. In this manner, uneven flow distributions in the vascular bed are diminished. Therefore reduced P_{ci} does not seem to be the effect of a redistribution of blood to areas of higher permeability.

In view of the above mentioned changes in CFC and PS, the reduction of P_{ci} is compatible with an increase in capillary permeability associated with a decrease in the reflection coefficient for plasma proteins. These experiments thus support the hypothesis that the sympathetic nervous system may control capillary permeability in canine subcutaneous adipose tissue[11]. Adrenergic vasomotor control of permeability has not been described previously.

Intracellular electric responses to sound in a vertebrate cochlea

ELECTRIC potentials generated by the inner ear in response to sound stimulation were first recorded 40 yr ago[1]. Studies

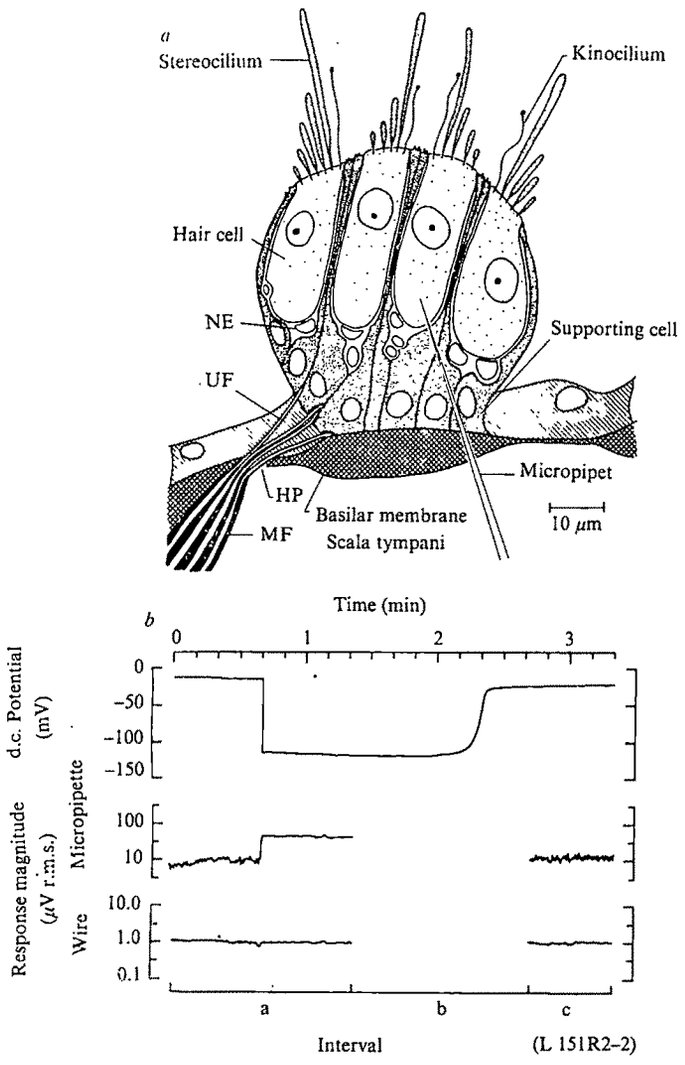

Fig. 1 *a*, Drawing of a transverse section through the basilar papilla of the alligator lizard. The basilar papilla is approximately 50 μm wide by 400 μm long and contains about 150 hair cells innervated by approximately 600 nerve fibres[24–26]. The penetration of the basilar papilla from scala tympani by a micropipette is shown schematically for a typical experiment. HP, habenula perforata; MF, myelinated portion of a nerve fibre; NE, nerve ending; UF, unmyelinated fibre. *b*, Oscillographic records obtained as a micropipette was advanced into the papilla. The top and centre traces were obtained from the potential recorded between the micropipette and a remote reference electrode. The top trace shows the d.c. potential; the centre trace shows the magnitude of the response to a 500 Hz tone at a sound pressure level (SPL) at the tympanic membrane of 75 dB. The bottom trace is the magnitude of the response to the 500 Hz tone obtained from a wire electrode near the round window. For both the centre and bottom traces the potential recorded from the electrode was passed through a narrow-band filter (2 Hz bandwidth) to obtain the fundamental component of the response, the magnitude of which is plotted on a logarithmic ordinate scale[27]. During intervals a and c, the 500 Hz tone was on continuously; during interval b, this tone was turned off and responses to other acoustic stimuli were recorded. When the d.c. potential suddenly dropped to −110 mV, the micropipette tip was assumed to have entered a cell, and the micropipette was held stationary. Coincident with the occurrence of the negative d.c. potential, the response magnitude increased abruptly by at least a factor of 4. After the d.c. potential returned to near zero, the magnitude of the response decreased almost to its previous value. The bottom trace shows that throughout the penetration by the micropipette into the basilar papilla, the response recorded from the wire electrode remained constant.

of these extracellular potentials have led to hypotheses about the role of intracellular potentials in sensory transduction in receptor (hair) cells[2,3]. It is difficult, however, to infer these intracellular potentials from extracellular measurements alone[4–7]; measurements of intracellular potentials from hair cells are clearly desirable. Although intracellular potentials in other hair-cell receptors have been reported recently[8,9], the few previous attempts to record such potentials in the cochlea have not yielded significant results[10]. We report here intracellular responses from single hair cells and supporting cells in the cochlea of the alligator lizard *Gerrhonotus multicarinatus*.

The lizard ear is basically similar to the mammalian ear[11,12]. Sound causes vibrations of the tympanic membrane which are transmitted by a cartilagenous extra-stapes and a bony stapes to the fluids of the inner ear, where the basilar membrane is set in motion. The auditory receptor organ (basilar papilla) consists of a strip of hair cells and supporting cells, which is on the basilar membrane (Fig. 1*a*). The basilar papilla is generally considered to be homologous[13,14] to the mammalian organ of Corti.

In our experiments, some bone and the round window membrane were removed so that the papilla could be visualised with a dissecting microscope. As a glass micropipette (tip diameter less than 0.5 μm) was advanced into the papilla (Fig. 1*a*) sound was delivered to the external ear and electric potentials were measured continuously. An abrupt negative shift in the d.c. potential was taken to indicate that the tip of the micropipette had entered a cell (Fig. 1*b*). (Intracellular d.c. potentials ranged between −25 mV and −125 mV in 90% of 547 cases with a median of −74 mV.) Stable negative d.c. potentials were often recorded for as long as 2 min and in a few cases for 30 min. The maximum displacement of the basilar membrane in these experiments (measured by the Mössbauer method[15]) was estimated to be less than 0.1 μm. Since this displacement is much smaller than the dimensions of the cells, it is not surprising that the micropipette tip could remain intracellular in the presence of this motion. Attempts to mark the cells after recording their responses to sound were made by passing current through dye-filled micropipettes[16,17]. Immediately after the experiment the intact papilla was dissected and the position and type of each dye-marked cell were determined by observation with a light or fluorescence microscope. For more precise localisation of the dye, the basilar papilla was sometimes embedded in Epon and serial sections were examined.

To assess whether the experimental procedures interfered grossly with the normal operation of the basilar papilla, extracellular responses were measured with a wire electrode on the bone near the round window. It was possible to expose the basilar membrane and to advance a micropipette into the papilla without significantly changing this extracellular response (Fig. 1*b*, bottom trace). The electric responses recorded intracellularly apparently did not result from mechanical vibration of the micropipette tip, because injection of sodium pentobarbital into scala tympani greatly reduced both the intracellular responses recorded with the micropipette and the extracellular response recorded with the wire electrode without changing the motion of the basilar membrane.

The intracellular responses to sound recorded in the papilla were graded potentials with a maximum amplitude of 3 mV peak-to-peak, and a short (less than 0.5 ms) latency in response to clicks. Responses to tone bursts had component waveforms that resembled the cochlear microphonic (CM) and summating (SP) potential that have been recorded extracellularly[2,18], suggesting that these intracellular response components (ICM and ISP in Fig. 2*a*) may be sources of the extracellularly recorded responses. Although the ratio of the magnitudes of ISP and ICM varies from cell to cell and is a function of stimulus parameters, ISP

was always a depolarisation. ICM was approximately sinusoidal with a fundamental frequency equal to the tone frequency (Fig. 2*b*).

Electric responses to sounds were of nearly the same magnitude in both hair cells and supporting cells, but the waveforms of the responses to clicks differ in these two types of cells[19]. The largest responses recorded (3 mV) from identified hair cells in the basilar papilla were comparable in magnitude with those reported for identified hair cells in lateral-line organs[8,9]. In contrast, the responses recorded in supporting cells were apparently larger (1.5 mV maximum) than those found in lateral-line organs[8,9]. All-or-none (action) potentials were never observed during penetrations of the basilar papilla, but were recorded during penetrations of the myelinated portion of the cochlear nerve at locations between the ganglion cell bodies and the habenula perforata (Fig. 1*a*).

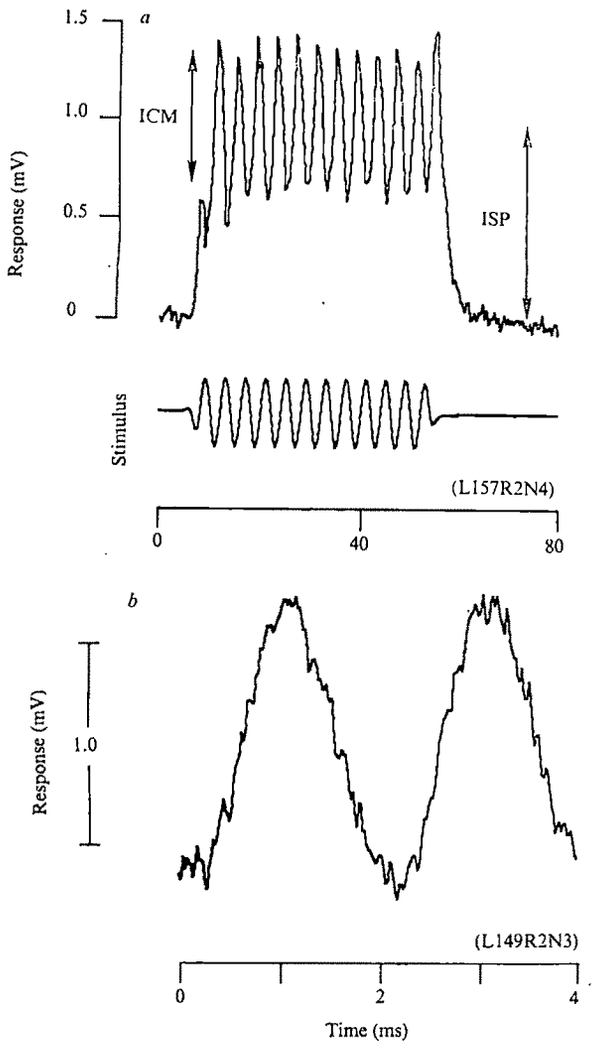

Fig. 2 *a*, Averaged intracellular response to tone-burst stimuli. Deviations of the potential from the resting potential are shown; upward direction is a depolarisation of the cell. The cell in which this response was recorded was identified as a supporting cell based on its response to acoustic clicks[19]. ICM (intracellular cochlear microphonic) is the response component that follows the individual cycles of the tone: ISP (intracellular summating potential) follows the tone burst envelope. The arrows indicate the approximate magnitudes of these components. Tone bursts of 50 ms duration were delivered at a rate of 10 s^{-1}. Rise-fall time was 2 ms. Frequency was 250 Hz and level was 94 dB SPL at the tympanic membrane. The average response was computed from 333 individual responses sampled at 400 μs intervals at 200 points. These points are connected by straight lines. *b*, Averaged intracellular response to a continuous tone recorded from a hair cell (as identified by dye-marking). Tone frequency was 500 Hz and level was 73 dB SPL. This averaged response was computed from 310 individual responses sampled at 20 μs intervals.

We should like to make some general comments about our results: (1) The existence of intracellular response potentials which are similar in waveshape but larger than the extracellular cochlear nucrophonic and summating potentials is consistent with the widely-held view that the cells of the sensory organ are sources of these extracellular potentials. The sodium pentobarbital-induced reduction of both intracellular and extracellular potentials is also consistent with this view. (2) The occurrence of responses of comparable magnitude in hair cells and supporting cells suggests either that supporting cells respond directly to sound and/or that hair cells are sources of currents which produce potentials in supporting cells. Thus supporting cells may play some role in the transduction process[19]. (3) The hair-cell afferent nerve junction is probably a chemical synapse[3]. Studies of chemical synapses indicate that presynaptic potentials of a few millivolts can produce changes in the release of transmitter substances[20,21]. Thus the receptor potential in hair cells may modulate transmitter release. (4) Studies of action potentials in single fibres of the auditory nerve[22,23] have demonstrated that during a tone burst (*a*) the mean rate of occurrence of action potentials is increased, and (*b*) action potentials tend to occur in synchrony with individual cycles of the tone. The fact that intracellular potentials in receptor cells have components (ISP and ICM) with waveshapes that are similar to the observed action-potential patterns is consistent with the view that these intracellular potentials may be a causal step in the excitation of action potentials in auditory nerve fibres.

Behavioural and physiological bases of drinking inhibition in water deprived rats

FLUID balance is normally precisely maintained. Yet, following water deprivation, neither rat nor man drink enough water to correct the incurred fluid deficit. Fluid balance is corrected, however, when food is also made available. Adolph[1] termed this phenomenon voluntary dehydration.

In this communication, experiments that identify the physiological and behavioural bases of voluntary dehydration are described. In preliminary analyses, to be reported elsewhere, we found first, that only 79% of the fluid lost by rats deprived of water for 24 h was restored by drinking; second, that water intake stopped in spite of a persistent intravascular deficit (estimated to be 20% from haematocrit and plasma protein measures[2]); and third that the cessation of drinking was closely associated with the development of cellular overhydration (based upon Leaf's treatment[3] of Na as an estimator of plasma volume). Specifically, 15 min after the start of drinking, 79% of drinking was complete and the cellular phase was estimated to be 1.5% overhydrated ($t = 2.217$, $d.f. = 15$, $P < 0.05$).

These correlational observations indicate the following alternatives regarding the determinants of voluntary dehydration. Intake may be exclusively controlled by the hydrational status of the cellular phase. That is, cellular overhydration may be the necessary and sufficient event to prematurely terminate drinking. This predicts that the manner in which cellular overhydration is attained by drinking compared with gavage, is irrelevant. Absorption may allow the mouth and stomach to control drinking either by metering fluid intake or by reducing the urge to drink. Both oral and postingestional information may be critical and drinking may stop because the ingestive act is closely related in time to its postingestive consequences.

To distinguish among these alternatives, ten adult female Sprague Dawley rats were each studied on nine occasions (including two baseline tests where sham preloads were given).

Table 1 Outline of deprivation, preloading and drinking schedule followed in this study

0 h	23 h	24 h	25 h
Water deprived	Preload	Preload	Preload
(Purina pellets available)	Intubate or drink water or 0.153 M NaCl*	Intubate or drink water or 0.153 M NaCl*	Drink water or 0.153 M NaCl for 5 h

* The amount given was 27.5% of the water loss.

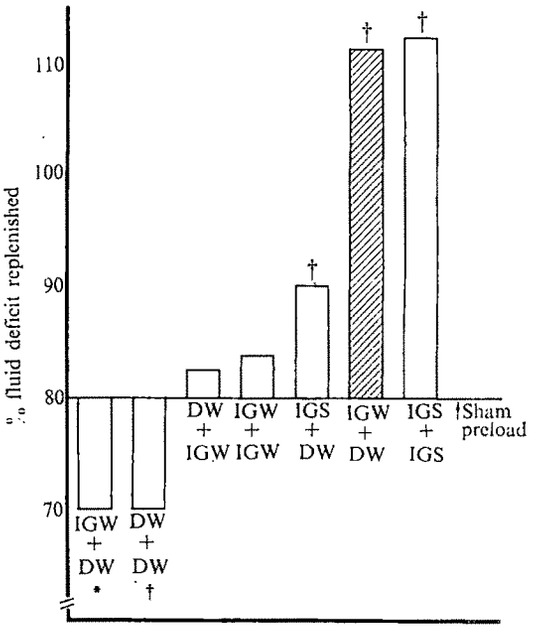

Fig. 1 Percentage of fluid deficits replenished in each of the eight conditions. % replenished = [(preload (ml) + test intake (ml))/water loss (ml)] × 100 The spontaneous drinking of sham loaded rats is presented as the baseline at 80%. IGW, Intragastric water; DW, drinking water; IGS, intragastric saline; DS, drinking saline. ☐ Water drunk during test; saline drunk during test. ▨ The first open column, for example, indicates that the first preload was water delivered intragastrically, water was drunk as the second preload and water was drunk during the 5 h test. * $P < 0.05$ † $P < 0.01$

Tests were separated by a mean of 7 d (range 4–10 d) and each rat was tested under a different semirandom order of preload and drinking conditions. The general procedure is presented in Table 1. On a given test, following 23 h of water (but not food) deprivation, food was removed and each rat drank, or received by gavage, one half of its fluid loss (approximated to be 67% of body weight loss[1]). One hour later the second half was either drunk or intubated. After another hour, either tap water or isotonic saline (0.153 M) was made available for 5 h. Food and water were then made continuously available until the next test.

Figure 1 compares total intakes (that is, the amount of preload and amount drunk during the drinking test) to the amount drunk spontaneously following sham loadings. In all but two conditions, total intake equalled or exceeded the amount drunk spontaneously following sham loadings. Total intake was actually reduced in the two exceptional cases (Fig. 1) and it was only in these two conditions that the second water preload was drunk following an initial water preload. Absorption of this volume of water was sufficient to produce cellular overhydration. Thus, only in situations in which development of cellular overhydration was closely paired with drinking, was premature termination of drinking exaggerated.

Cellular overhydration *per se* was not the critical event terminating drinking. If it were then the outcomes of the first four conditions, in which identical water preloads were delivered, and comparable haemodilution occurred, should not have differed one from another.

Neither the amount of the preload drunk nor the time spent in its drinking were the determining factors. If they were, then intake following the DW+DW sequence (see Fig. 1) should have been the most suppressed. Drinking here did not differ however, from the IGW+DW condition where only one half of the preload was drunk. Moreover, if oral metering *per se* were the critical factor, then intake following IGW+DW should not have differed at all from that following the DW+IGW sequence. As seen in Fig. 1, however, intakes differed markedly.

The IGS+DW condition (Fig. 1) indicates that the prevailing factor in the first two conditions was not the memory of having recently drunk water. Here the preload of DW followed intragastric isotonic saline. That is, drinking occurred in the absence of cellular overhydration. This emphasises that when water intake is divorced from cellular overhydration, drinking continues.

The shaded column of Fig. 1 (the test solution isotonic saline) suggests that the efficacy of treatment IGW+DW resided in the inhibition of water ingestion and not in thirst reduction. If it were the elimination of thirst, then no drinking should have occurred during the test hour regardless of the proffered solution. Yet a considerable volume of saline was ingested presumably in response to the prevailing extracellular deficit. This is an important aspect of the phenomenon for it raises the possibility that inhibition of drinking is specific to the solution drunk during the development of cellular overhydration. The final column emphasises the importance of cellular overhydration. When the entire preload was isotonic saline, a solution which has little initial effect on cellular balance, water intake was very substantial (9.4 ml).

The only conditions that exaggerated voluntary dehydration were those in which water intake occurred in contiguity with cellular overhydration; namely, drinking the entire water preload or intubating the first half of the preload and drinking the second half. Intubation of the entire preload or drinking the first half and tubing the second half did not have this effect.

These data provide the behavioural and physiological bases for the natural occurrence of voluntary dehydration in rats and indicate that: as drinking ensues, water is quickly cleared from the stomach and absorbed[4]; the cellular phase becomes rapidly overhydrated, and this occurs while the rats are actively engaged in drinking; the water remaining in the stomach and intestine is cleared, absorbed, and excreted in a dilute urine. The exaggeration of voluntary dehydration is likely a result of allowing ample time for complete absorption following the preloads and thereby avoiding any lag in the system.

The above theory predicts therefore, that even if the entire amount drunk were to be preloaded by gavage, drinking would still occur. This is precisely what happened. Ten rats preloaded a mean of 14.7 ml (the gross intake of a previous test) drank an additional 3.0 ml (range 1.0–5.0 ml) despite the fact that the preload caused substantial overhydration ($\bar{X}=7.1\%$).

The implications of this report may extend beyond voluntary dehydration to include other ingestive phenomena. For example, Nachman and Valentino[5] have shown that adrenalectomised rats, although intubated with the amount of NaCl required to satisfy their salt deficit, drank a considerable amount of 0.3 M NaCl. There have also been reports that water delivered by gavage is not nearly as effective as water taken by mouth in reducing intake to either intravascular depletion by hyperoncotic colloid[6] or to intracranial angiotensin[7]. According to Fitzsimons, rats infused with their normal daily water requirement still drink significant amounts[8]. Janowitz and Grossman[9] have shown that loading food intragastrically 20 min before regular feeding failed to depress intake in dogs. Baille *et al.*[10] reported that intragastric intubation of glucose inhibited feeding only when the load was delivered concurrently with feeding. If the load was delivered 30 min in advance of feeding, there was no suppression. Miller[11] has presented extensive evidence that rats work for more food or water following intragastric preloads than following oral preloads. These data have, in general, been intrepreted from the 'drive stimulus reduction' point of view, or with the idea that the mouth in some way meters the amount of ingesta appropriate to the animals' requirement. In light of the present evidence, these interpretations might be re-evaluated and the influence of ingestion in contiguity with its postingestional consequences explored.

Optical polarisation indicates linear arrangement of rhodopsin oligosaccharide chain in rod disk membranes of frog retina

RHODOPSIN, the visual pigment of the retinal rods, is a doubly conjugated protein constituting about 80% of the total protein of the rod disk membrane in the frog[1]. The two prosthetic groups of rhodopsin are the visual chromophore retinal, and a single oligosaccharide chain comprising six sugar residues[2,3].

Electron microscope[4,5,6] and X-ray diffraction[7–10] studies offered no evidence for the orientation of the chromophore molecules or the oligosaccharide chains of rhodopsin with respect to the plane of the disk membrane. The negative, dichroism of the outer segments with the greater absorption for light polarised perpendicularity to the rod axis[11,12] indicated that the chromophore molecules are oriented with their long axis parallel to the plane of the disk membranes. That no dichroism in the axial direction could be observed, indicates that the chromophore molecules are scattered randomly in all directions with their lengths in the plane of the membrane. It was found recently[14,15] that when a flash of linearly polarised light passed along the lengths of the rods, axial dichroism was induced as a result of bleaching of the retinal molecules lying parallel to the plane of polarisation

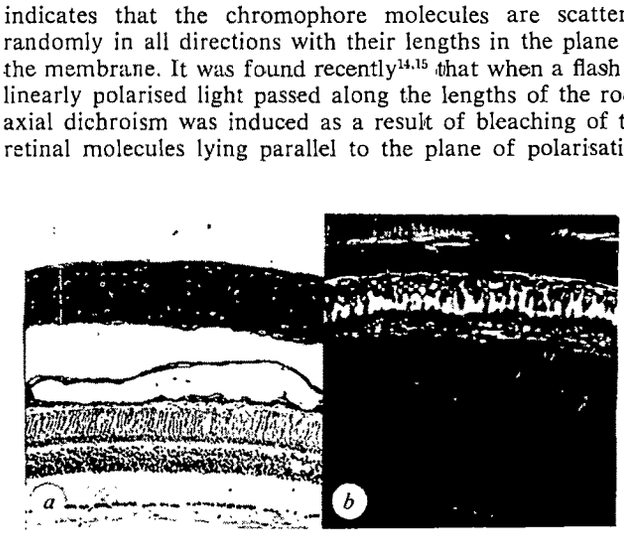

Fig. 1 Paraffin section of formaldehyde-fixed frog retina, depigmented with H_2O_2 and stained with 0.1% toluidine blue at *p*H 3.0 for 5 min. After blotting off the dye solution, the staining effect was stabilised with 2% potassium ferricyanide[20] and mounted in gum arabic which was allowed to dry; *a*, in the light microscope, at this *p*H, only the cell nuclei appear stained the rod outer segments show no dye binding. At the top the basophilic scleral cartilage is seen; *b*, the same field with the polaroids crossed. The ground substance of the cartilage shows strong toluidine blue induced birefringence[20]. Above the cartilage birefringent collagen fibres are seen.

of the light used. This dichroism, however, was very short lived and rapidly decayed with a relaxation time of about 12 ms, but was more persistent in glutaraldehyde-fixed rods. It was concluded that in the native state rhodopsin molecules were free to undergo rotational (Brownian) motion, however, with the chromophore remaining in the plane of the disk membrane. This would indicate a relatively fixed rotation axis of the rhodopsin molecules perpendicular to the plane of the membrane.

Thus rhodopsin seems to be highly oriented in the photoreceptor membrane[16,17], which seems to be of great functional importance[18]: it secures the greatest possible absorption of incident light of all possible vibration planes by way of the membrane parallel orientation of the chromophore molecules and by the rotational motion of rhodopsin.

The question can be raised whether the hydrophilic oligosaccharide chain of rhodopsin has a definite form and arrangement with respect to the plane of the membrane, indicating its possible contributory role in the maintenance of the order of rhodopsin in the disk membrane. So far no information about the steric arrangement of the oligosaccharide chain of rhodopsin has been available.

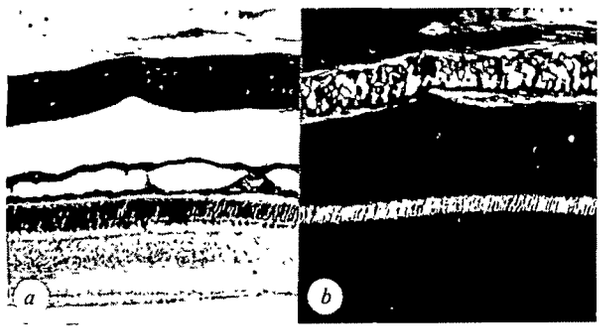

Fig. 2 After depigmentation and preoxidation with 0.1% HIO_4 (30 min) the slice was kept in aqueous saturated sodium bisulphite (30 min) and then stained with toluidine blue at *p*H~1.0, stabilised with potassium ferricyanide. *a*, At this *p*H the cell nuclei remained unstained but there is strong basophilia of the outer segments of the retinal rods, sharply delineated against the unstained inner segments. (The basophilic granules—with weak mosaic-like birefringence in (*b*)—seen around the cell nuclei in the scleral row of the outer nuclear layer were glycogen granules and could be removed by diastase.) At the top the basophilic scleral cartilage is seen; The same area as in, (*a*) with the polaroids crossed. The basophilic outer segments reveal a strong toluidine blue-induced negative birefringence with respect to their lengths, with retardations of about 30 nm at 600 nm. The cartilage shows strong toluidine blue induced birefringence[20].

Since we have developed a polarisation optical method for demonstrating linearly ordered glycol groups in polysaccharide chains, we have used this method in an attempt to decide whether the oligosaccharide chains of rhodopsin have a definite orientation with respect to the plane of the disk membrane. The method is based on the preoxidation by periodic acid of the vicinal OH groups, or amino–alcohol groups, of carbohydrates to dialdehyde groups, which after addition of sodium bisulphite, become negatively charged and able to bind toluidine blue at *p*H 1.0. This results in strong basophilia of the reacting compounds as reported for glycogen[19] and, as we have found, in a strong toluidine blue induced birefringence: negative in character with respect to the oligosaccharide chains when they are present in a linear order (as in neutral mucins, basement membranes and starch granules). As all the carbohydrate residues of the oligosaccharide chain of rhodopsin (three glycosamine, two mannose and one galactose) may be expected to react with periodate[20] as confirmed by the strong periodic acid Schiff reaction of the rod outer segments, the method proved promising for the investigation of whether or not the carbohydrate chain of rhodopsin was arranged in a definite order with respect to the plane of the disk membrane.

Dark-adapted retinae of the frog (*Rana esculenta*) were fixed by perfusion from the aorta in 10% formaldehyde solution, in a mixture of formaldehyde (5%), and glutaraldehyde (2%), and in Zenker fixative. Good polarisation optical results were obtained with formaldehyde and Zenker. Glutaraldehyde, a bifunctional cross-linking agent markedly depressed the optical effect, but not the induced basophilia, apparently because of the extensive cross linking of the underlying structure, which inhibits oriented dye binding. Paraffin slices were investigated in the light and polarisation microscopes. Data on the periodic acid bisulphite addition (PA-BSA) reaction and toluidine blue staining are included in the legend of Fig. 1. In Fig. 1*a*, the rod outer segments do not stain with toluidine blue at *p*H 3.0 and are isotropic in the mounting medium used (Fig. 1*b*). After PA-BSA reaction and toluidine blue staining (Fig. 2*a*) the outer segments reveal strong basophilia sharply delineated against the inner segments and corresponding to the staining with the PAS reaction, both indicating the presence of vicinal OH groups in great density in them. After the PAS reaction, however, the outer segments are optically isotropic, which means that this histochemical reaction of the vicinal OH groups gives no information about the molecular structural order of the underlying carbohydrate component in the photoreceptor membranes. On the other hand after PA-BSA reaction and toluidine blue staining the basophilic outer segments appear strongly birefringent (Fig. 2*b*) with a dispersion curve of their birefringence as a function of the wave length of the light as shown in Fig. 3. In it a diagram is included to show the underlying molecular mechanism of the PA-BSA reaction and the oriented toluidine blue binding of the carbohydrate chain with the resulting anisotropy.

It is obvious that optical anisotropy as a result of oriented molecular textures[22]. Therefore, the toluidine blue-induced anisotropy of the outer segments after PA-BSA reaction cannot be explained as arising either on randomly

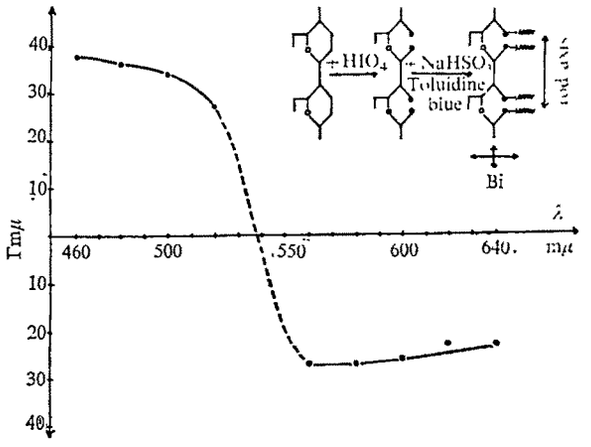

Fig. 3 Dispersion curve of the toluidine blue-induced birefringence of the rod outer segments of Fig. 2 *b*, which are negatively birefringent for light of wave length over λ 540 nm and positive under λ 530 nm. In the zone of immersion (· · · · · · · · · ·) no exact measurement of birefringence was possible. The inversion of birefringence is the result of anomalous dispersion of the refractive indices of toluidine blue when present in an oriented system[21]. As a result of the dispersion of the toluidine blue induced birefringence anomalous colours were seen: blue at additive, and red at subtractive compensation. The negative birefringence for the long-wavelength side of the spectrum indicates membrane-parallel orientation of the dye molecules[21] and in turn, membrane perpendicular orientation of the reacting oligosaccharide chains of rhodopsin.

arranged straight oligosaccharide chains or on irregularly bended oligosaccharide chains of the rhodopsin molecules. Thus, from these polarisation optical findings it may be concluded that the oligosaccharide chains of rhodopsin have a straight linear form oriented perpendicularly to the plane of the disk membrane.

It seems reasonable to assume that these straight hydrophilic carbohydrate chains of the rhodopsin molecules protrude into the aqueous area of the disk membranes. In this way they may form an axis for each rhodopsin molecule, which may well act as an axis for their rotational motion as inferred from the polarisation optical studies of Brown[13] and Cone[14], and suggested by Vanderkooi[23] in his membrane model. It is interesting to note that Heller[2], who was the first to demonstrate the oligosaccharide chain as an integral part of rhodopsin, suggested that by hydrophilic interactions the carbohydrate moiety probably served as an orientation factor for the rhodopsin molecules in the membrane. Corless[24] even assumed that the carbohydrate chains might serve as rotation axes for the rhodopsin molecules, although there had been no evidence for a definite orientation of these side chains with respect to the plane of the disk membrane. Our polarisation optical observation indicating a straight form of the oligosaccharide chains of rhodopsin with perpendicular orientation to the plane of the disk membrane, strongly supports such a view on the structural-functional significance of this part of the rhodopsin molecule.

Adaptation to invisible gratings and the site of binocular rivalry suppression

THE visual system can be described usefully as a hierarchical series of functional stages, the initial stage being physical impingement of the stimulus and the terminal stage being visual perception. Psychophysical investigations typically provide rigorous specification of the first and last stages in the sequence, but a more complete explanation clearly must include information about intermediate stages as well. At present, however, very few techniques are available for analysing inferentially the intermediate stages[1]. By incorporating two separate phenomena, binocular rivalry and visual aftereffects, into one paradigm, we describe here another technique for inferential analysis of the stages leading to vision. This technique indicates the sequence of stages underlying both phenomena.

Binocular rivalry refers to the transitory, phenomenal suppression of each eye's view produced when the two eyes receive different stimulation[2]. Even though a rivalry-inducing stimulus continuously impinges on the retina, it is only intermittently visible. Several characteristics of rivalry indicate that it is a reflexive process, the suppression state resembling in many ways a central scotoma[3–7]. Visual aftereffects refer to temporary perceptual distortions produced by prolonged exposure to a stimulus, some familiar examples being the waterfall illusion[8], figural aftereffects[9], and the more recently discovered McCollough effect[10]. Up to a limit, the magnitude of most aftereffects increases with duration of exposure. This property of aftereffects, coupled with the unique dissociation of physical stimulation and phenomenal viewing characteristic of rivalry, provides the keystone to the technique reported here. Imagine that an aftereffect-inducing stimulus impinges on an eye for a certain duration, but at the same time is phenomenally suppressed for a substantial portion of that time because of binocular rivalry. If the inducing stimulus remains effective while suppressed, the magnitude of the aftereffect will correspond to the duration of physical stimulation. But if the stimulus is rendered ineffective by suppression the aftereffect will be weakened, and its magnitude will correspond to the duration of phenomenal viewing. We have applied this technique using two spatial frequency aftereffects, both of which are induced by prolonged exposure to a grating pattern of repetitive light and dark bars. One aftereffect is an elevation in threshold contrast[11], and the other is a shift in apparent spatial frequency[12]. Both aftereffects are limited to gratings similar in spatial frequency and orientation to the adaptating grating. We have found that suppression exerts no influence on the growth of either of these aftereffects, and take this as evidence that the stage where suppression occurs is located subsequent to the site of these aftereffects.

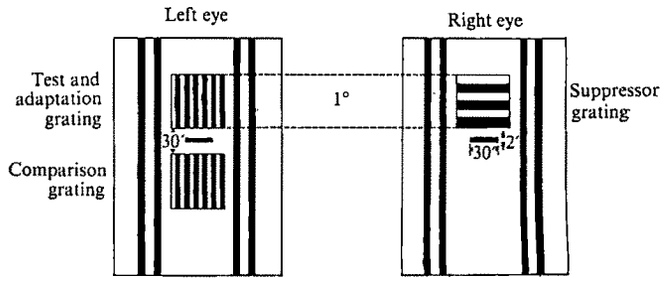

Fig. 1 The haploscopic stimulus arrangement used to induce and measure the spatial frequency after effects. Spatial frequency (number of cycles of the grating per degree of visual angle) and contrast (difference between the maximum and minimum intensities in the grating divided by their sum) could be altered, and the gratings turned off or on, without disturbing the mean luminance, 17 cd m^{-2}.

The displays used in our experiments are illustrated in Fig. 1. Squarewave gratings, masked to 1° square by transilluminated plastic sheets, were generated on cathode-ray tubes[13] mounted onto the arms of a large haploscope. Subjects viewed the displays from a distance of 91.6 cm through 3 mm artificial pupils, with head movements minimised by a bite-board and headrest. Space-average luminance of each grating was 17 cd m^{-2}, independent of spatial frequency or contrast, and the luminance of the masks was 5.1 cd m^{-2}. Each grating could be turned off or on without changing the average luminance. With the two displays

fused, the horizontal suppressor grating appeared in binocular coincidence with the upper left-eye grating, with a small fixation bar appearing immediately below. Thin vertical stripes on each side of the gratings facilitated fusion of the two displays.

We used a matching procedure to measure the aftereffects. While staring at the fixation bar, subjects quickly adjusted the test grating, using a potentiometer, to match the comparison grating on the basis of either contrast (experiment 1) or spatial frequency (experiment 2), offsetting the potentiometer after each adjustment. During these adjustments the right-eye suppressor grating was turned off. Adjustments were made before and immediately after exposing the left eye to an adaptation grating which temporarily replaced the test grating. During this adaptation period the subject gazed back and forth along the fixation bar to discourage formation of an afterimage. Each experiment consisted of four conditions of adaptation: (*a*) condition T—the adaptation grating was continuously present and visible for t s, with the right-eye suppressor grating turned off; (*b*) condition 2T—the adaptation grating was continuously present and visible for $2t$ s, with the suppressor grating off; (*c*) condition BR—the adaptation grating was physically present for $2t$ s but was seen for a total of no more than t s due to rivalry suppression produced by the suppressor grating presented to the right eye; and (*d*) condition RM—the adaptation grating was physically present and visible for t s distributed intermittently over $2t$ s, intermittency being produced by alternately exposing the left-eye adaptation grating and the right-eye suppressor grating following a pattern mimicking the fluctuations of rivalry. Each trial thus involved a preadaptation match of the test grating to the comparison grating, exposure to one of four adaptation conditions, followed immediately by a postadaptation match of the test grating (which fell on adapted retina) to the comparison grating (which fell on unadapted retina). Seven trials were devoted to each adaptation condition, the order of trials being haphazard. On each trial of condition BR, subjects continuously reported on rivalry fluctuations using a switch connected to an event recorder. Subjects rested at least 5 min between trials, until the aftereffect had dissipated.

Before an experiment, two adaptation durations, different by a factor of 2, were selected for each subject to maximise differences in the magnitude of the aftereffect under study. Only durations of 60 s or less were selected, for beyond this period the magnitude of the aftereffects no longer increased. Also, the spatial frequency and contrast of the adapting grating were adjusted for each subject to insure at least 50% suppression of the adaptation grating. Of three subjects, two were naive regarding the purpose of the experiments.

In experiment 1, the comparison grating was set for each subject at threshold contrast, and the spatial frequencies of the test, comparison, and adaptation gratings were identical. For two subjects the left-eye gratings were 3 cycles per degree, while for the remaining subject they were 6 cycles per degree. For each subject the contrast of the adaptation grating was approximately 1 log unit above threshold. With these spatial frequency and contrast values, the adaptation grating was suppressed for at least 50% of the adaptation period on each trial of condition BR, as determined from the graphic records of rivalry. The duration of adaptation t (condition T) varied from 15 to 30 s among subjects. The results from this first experiment are summarised in the graphs of Fig. 2*a*, which show for each subject the magnitude of the elevation in threshold contrast produced by each of the four conditions of adaptation. While all conditions produced some adaptation, the aftereffect for condition BR was significantly greater ($P<0.01$, t test) than either condition T or RM and was at least as large as that for condition 2T. Control trials were included to determine (i) if the suppressor grating alone influenced the visibility of the test grating, (ii) if the effects of the adaptation grating spread to the comparison grating, and (iii) if the aftereffect was limited to frequencies similar to that of the adaptation grating. Results confirmed that the aftereffect was frequency specific and unconfounded by either the suppressor grating or by interaction between the adaptation and comparison gratings. Considered together, this pattern of results demonstrates that suppression exerts no influence on the growth of the threshold elevation aftereffect.

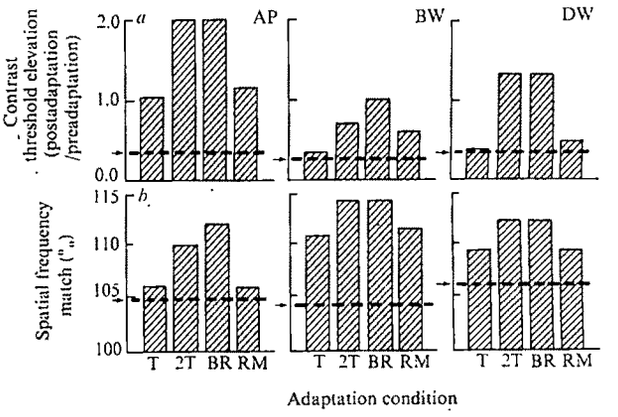

Fig. 2 The three bar graphs in (*a*), one for each subject, show the magnitude of the elevation in threshold contrast for four conditions of adaptation. Each value represents the mean ($n=7$) ratio of the adapted threshold to the unadapted threshold, minus 1.0. No aftereffect is thus represented by a value of 0.0. The arrow and dashed horizontal line indicate for each subject the level of significant threshold elevation (a ratio value equivalent to $2\sqrt{2}$ times the standard error of the unadapted thresholds). The average standard error for adapted thresholds was only about 0.03 log units. The three bar graphs in (*b*) show the magnitude of the shift in apparent spatial frequency, expressed as the mean ($n=7$) percentage difference from unadapted frequency matches. No aftereffect would yield a value of 100. Again the arrow and dashed lines mark the level of significant aftereffect, based on unadapted standard errors.

In experiment 2, in which we studied the size aftereffect[12], the spatial frequency of the comparison grating was 6 cycles per degree and the adaptation grating was 8 cycles per degree; all gratings were 1 log unit above threshold contrast and the durations t varied from 15 to 30 s among subjects. Results from this experiment, shown in Fig. 2*b*, follow the same pattern of results and significance found in the previous experiment. Because this aftereffect involves a change only in spatial frequency, not in contrast, these results extend the generality of those obtained in the first experiment.

In both instances the magnitude of the aftereffect was determined solely by the duration of physical impingement, phenomenal suppression exerting absolutely no influence. Yet from other data we know that suppression exerts potent inhibitory effects, at both the psychophysical[3–5] and electrophysiological level[6,7]. Thus the failure of suppression to weaken either aftereffect must mean that spatial frequency information arrives at the locus of the aftereffects even during suppression. This in turn implies that the neural mechanism responsible for suppression resides within the visaul system after the site of the aftereffects which is generally presumed to be visual cortex[11,12,14]. Our conclusion is based, of course, on the quite plausible assumption that pattern information is processed in serial fashion from eye to cortex.

Our experiments have helped to clarify the interaction between pattern adaptation and rivalry suppression. The technique of functionally uncoupling stages of the visual system by means of suppression, however, seems generally

applicable to other phenomena involving time-dependent effects and suppressible stimuli.

Memory in enzyme membranes

THE problem of information storage in the phase of 'short term memory', has attracted considerable attention. A plausible mechanism for the process is based on an all-or-none process, assuming the existence of metastable states[1,2]. Such phase transitions were thought to require structural changes in macromolecular components or in the membrane permeability of the information storage unit[3–5].

The rapid development in the techniques of manufacturing synthetic enzyme membranes[6] provides a new tool for demonstrating the existence of hysteretic phenomena which do not occur as a result of structural changes in a system.

The idea is based on studies by chemical engineers in which cooperative effects resulting from a nonlinear temperature dependence of rate coefficients were investigated from the point of view of the stability of chemical reactors. The existence of multiple stationary states was demonstrated for a reaction mixture having different reaction rates for the chemically controlled region and the diffusion-controlled region under the same external parameters. As a result the possibility of hysteresis and oscillations in internal parameters of the systems when coupled with thermal flows arose and was discussed[7].

In analogy to these results, we demonstrate here the existence of hysteretic phenomena, through simple kinetic mechanisms which are shared by most enzymes. We refer to the two simple cases; autocatalysis by the product, and inhibition by excess substrate. Both are examples of systems which do not satisfy the Le Chatelier-Braun principle, and the phenomenon never takes place along the whole range of concentration values, thus resulting in a maximum in the activity. When coupled with diffusion of the product of substrate respectively, there is, because of the nonlinearities in the reaction rate, the possibility of three stationary states, of which two are stable and one unstable, for a limited range of parameter values[8].

Two enzymatic reactions were studied. The hydrolysis of benzoyl arginine ethyl ester (BAEE) by papain (EC3.4.4.10) and the oxidation of uric acid by uricase (EC1.7.3.3). In both systems displaced far from equilibrium (namely, high *p*H for the papain system (of which the product is a strong acid, *p*H=3.38) or excess of substrate for the uricase system) an autocatalytic effect of the product, or substrate inhibition, respectively is seen. When the reagents are subject to diffusion limitation (for example when bound to a membrane matrix), the description 'stationary state' implies equal rates of supply and consumption through the diffusional flows and the chemical processes, at any point in the reaction space. The rate of hydrolysis is a function of BAEE concentration, hydrogen ion concentration and their diffusivities, and the rate of oxidation is a function of uric acid concentration, oxygen concentration, and their diffusivities. Under zero order kinetics for the oxygen or BAEE, a degree of freedom is lost, thus eliminating the occurrence of oscillatory behaviour, demonstrated previously[9,10], and forcing the systems to remain in one of the two stable stationary states, depending on its history.

Two different methods were used in these studies. The papain membrane was produced on the surface of a rotating *p*H glass electrode, by pouring a solution of collodion (3%, w/v), in ether (48%), ethanol (50%) and water (2%), on the surface of the electrode bulb (Metrohm, 'combined', while rotating horizontally around its revolution axis at 100 r.p.m. After 2–3 min, the membrane-electrode was introduced into

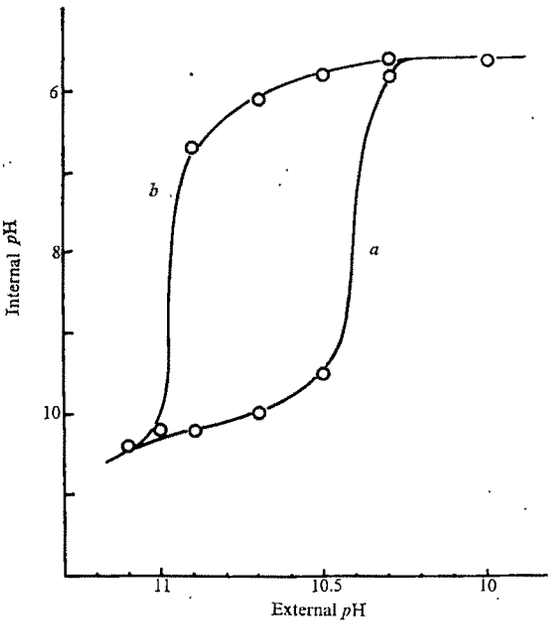

Fig. 1 Papain membrane-coated electrode. Stationary state description of internal *p*H as a function of increasing (*a*), and decreasing (*b*), the external *p*H values. The experiment started with decreasing the *p*H and then increasing. (See text for details.)

a solution of nonactivated papain (1 mg ml^{-1}), 0.1 M KCl for 3 d in 4° C (ref. 11), and then introduced to a solution of glutaraldehyde (0.5%) in phosphate buffer (0.02 M, *p*H 6.8), for 3 h at room temperature. The immobilised enzyme was activated by immersion in a solution containing EDTA (1 mg ml^{-1}), cysteine (1 mg ml^{-1}) and 0.1 M KCl, and then introduced in water, at 60° C, for 90 min, to cause partial denaturation, and to reduce the activity. It was then reintroduced to the cysteine EDTA solution, substrate was added and the *p*H at the electrode-membrane interface was recorded as a function of time and external *p*H. The results are given in Fig. 1, showing a hysteresis loop with two steep transitions, from *p*H 9.7–5.8 and from *p*H 6.7–10.2. Each point describes a quasistationary state of the system under constant external *p*H, controlled by a *p*H-stat appa-

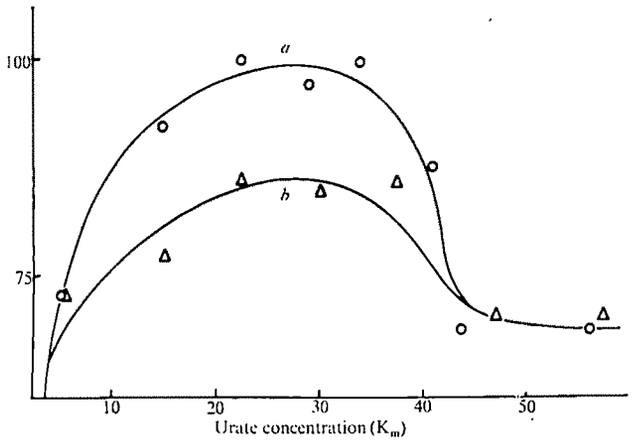

Fig. 2 Uricase membrane immersed in a solution of substrate. Enzyme activity (IU) as a function of the substrate concentration in the bulk solution. Results are given for increasing (*a*) and decreasing (*b*) substrate concentration value. (See text for details.)

ratus adding NaOH. At each point, an additional amount of substrate was added, verifying zero order kinetics. Because of the high rate of BAEE hydrolysis catalysed by hydroxyl ions at *p*H values higher than 10.5, compared with the low reaction rate, excess substrate was also verified at the end of the experiment. This was done by reducing the *p*H of the solution to 7, removing the electrode, adding papain to the solution and monitoring the amount of base added. The external *p*H was first lowered and then raised to eliminate an apparent effect due to possible loss of activity.

The uricase membrane was produced on a plane glass surface. A cross-linking reaction occurred for 2 h in a solution containing 30 mg ml^{-1} albumin, 2 mg ml^{-1} glutaraldehyde and 50 mg ml^{-1} uric acid in phosphate buffer 0.02 M, *p*H 6.8. Before spreading on the glass surface, 0.5 mg ml^{-1} of uricase was added to the solution[12]. To stir and to reduce the mass transfer problems of oxygen, the measurements were performed with several pieces from the same membrane. The pieces were immersed in a buffered solution of substrate (glycine-NaOH buffer, *p*H 3.3, 0.05 M) and put in continuous air bubbling. A time gradient of urate is established by a controlled pumping (chemical stat) and the rate of substrate consumption was recorded spectrophotometrically at 293 nm. Though the oxygen concentration in the system is much lower than the urate concentration, zero order kinetics for oxygen exists because the oxidation of urate to allantoin is the rate limiting step in the reaction chain[13].

The kinetic behaviour of both enzymes, in solution, was extensively studied[14,15] and no metastable states were found. It is clear that the memory which had been introduced into the above systems by diffusion limitations is more probable than a memory mechanism based on molecular hysteresis. It demonstrates once again the importance of taking structural influence into account, especially when dealing with complex biological systems bearing enzymes.

Correlation between speed of pollen tube growth and seedling height in *Zea mays* L.

EVIDENCE of a correlation between gametophytic and sporophytic qualities could be useful because gametophytic competition is both frequent and severe in natural populations[1]. A statistically significant correlation has been found in *Zea mays* between the relative speeds with which pollen tubes penetrate the lengths of styles and the relative competitive abilities of the resultant zygotes[2]. This correlation was found in a study of mixtures of two pollen types when the sporophytic competition was limited to interactions between zygotes developing within a common inflorescence. It is therefore possible that faster growing pollen tubes allow a relatively early start in postfertilisation growth which accounts for the competitive superiority of the resultant zygotes, although there is a conflicting report[3].

The present study was designed to test for correlations between relative speed of pollen tube growth and relative seedling weight, avoiding the possible influence of differences in time of fertilisation. Pollen types, of known tube growth rates, were each applied to separate inflorescences on plants of known genotypes. Five replications of each cross were made. All genotypes used were highly inbred and none of the crosses was a self pollination. The relative speeds of pollen tube growth were determined by the certation technique[4], modified to allow quantitative expression of the results[2].

From each of the 35 well-filled ears produced by the unmixed pollinations of the present study, 36 seeds were removed from the middle segment, avoiding the extreme sizes of apical or basal seeds. Seeds were weighed individually and planted singly in sand-filled pots 2 inches square in size. The environment was controlled at 22±1° C, 2,500 f.c., and daylength 18 h. Fourteen days after planting, seedlings were cut at ground level and weighed.

The data were subjected to partial correlation analysis with three variables: the relative speed of faster growing tubes[2], relative seedling weight and relative seed weight (see legend to Table 1). Partial correlation analysis tests for correlations between any two factors and, in effect,

†Average weight of seedlings resulting from fertilisations by gametes of the faster growing tubes divided by that from fertilisations by gametes of the slower growing tubes.
‡Average weight of seeds from fertilisations by gametes of faster growing tubes divided by that from fertilisations by gametes of the slower growing tubes.
§Faster pollen of the pair.

removes the influence of additional factors. Thus, in the present study, the value $r_{12.3}$ refers to the correlation between the first two factors, relative pollen tube speed and relative seedling weight, when the influence of the third factor is removed (Table 2).

The partial correlation between relative pollen tube speed and relative seed weight, $r_{13.2}=0.566$, is not statistically significant, nor is that between relative seedling weight and relative seed weight ($r_{23.1}=-0.241$). The latter result does not indicate that relative seedling weight and relative seed weight are generally independent of each other, it just means that in this study, no statistically significant portion of the variation in one factor could be attributed to variation in the other factor. This is understandable in that a separate analysis of variance (not presented here) indicated that if each inflorescence receives pollen from only one plant, weights of seeds resulting from fertilisations by gametes of the relatively fast pollen tubes do not differ significantly from weights of seeds produced by gametes of relatively slow pollen tubes, a conclusion in agreement with that of Jones[4].

Table 2 Correlation and partial correlation analyses for relative pollen tube speed, relative seedling weight, and relative seed weight.

r_{12}	= 0.781*
r_{13}	= 0.608
r_{23}	= 0.355
$r_{12.3}$	= 0.761*
$r_{13.2}$	= 0.566
$r_{23.1}$	= −0.241

*Significant at the 5% level.
r_{12}, correlation coefficient between the first and second factors.
$r_{12.3}$, partial correlation coefficient between the first two factors with the influence of the third removed.

The partial correlation coefficient between the first factor, relative pollen tube speed, and the second, relative seedling weight, with the influence of the third, relative seed weight, removed is $r_{12.3}=0.761$, which is significant at the 5% level (d.f.=5 with two variables) (ref. 5). This demonstrates that a significant number of genetic factors which are expressed in the gametophyte are also expressed in the sporophyte.

This statistically significant correlation between relative pollen tube speed and relative weight of the resultant seedlings cannot be due to differences in time of fertilisation because there were no interactions between the two types of zygotes. It also suggests that seedling vigour, a selectively important quality[6], can be influenced by gametophytic competition.

This study was supported by a grant of the National Institutes of Health and, in part, by a grant from the National Science Foundation.

Heterocyst formation in a blue-green alga, *Cylindrospermum*

THE blue-green alga *Cylindrospermum*, unlike a similar alga, *Anabaena*, where intercalary heterocysts are present, contains only two terminal heterocysts (Fig. 1*A*). When either or both the heterocysts are detached, new heterocysts regenerate in time. In *Anabaena cylindrica*, where the heterocysts occur at regular intervals, the spacing pattern is determined by intercellular interactions, probably involving some inhibitory substance produced by the heterocyst itself. No two heterocysts are produced side by side either in *Anabaena* or *Cylindrospermum*. The inhibitory substance could be ammonia or a substance derived from ammonia[1]. Here we report observations which indicate that an inhibitor controls the spacing of heterocysts.

Clonal cultures of *Cylindrospermum trichotosporum* were grown on Allen and Arnon's medium[2], both on solid and liquid media. In some experiments it was also cultivated on media containing combined nitrogen, ammonium chloride (3 mg ml^{-1}) or ammonium phosphate (3 mg ml^{-1}). The growth and formation of heterocysts was followed by the methods described by Kale *et al.*[3]. Algal material, generally 15 d old, was suspended in fresh medium and blended in a modified kenmix blender for 0.5—1 min and after dilution, drops of the suspension were placed on agar plates. Selected filaments were focused under the microscope and observations made.

The number of vegetative cells present between the two terminal heterocysts is a fixed characteristic of an algal population for a particular set of culture conditions in *Cylindrospermum*, the average length of the filament between the two heterocysts is 418 μm (107 cells). On liquid media with constant shaking, filaments tend to be longer than the average and while on agar, the spreading filaments break into two, usually each fragment having a single heterocyst, generally 111–150 μm (21-28 cells) long. When the filaments are broken into fragments by blending at high speed, the fragments so formed also have a single heterocyst and are of a similar range in length (111–130 μm). This seems to indicate the presence of naturally occurring weak points of breakage in the filaments of *Cylindrospermum*.

Table 1 Growth needed before the formation of first heterocyst in fragments of *Cylindrospermum* grown on various media.

Control (Allen and Arnon's medium)	36*	54†
Medium with ammonium chloride, 3 mg ml^{-1}	55*	41†
Medium with ammonium phosphate, 3 mg ml^{-1}	51*	18†

* % increase in length.
† No. of observations.

Fragments of filaments with one heterocyst still attached, produced by natural breaking or by high speed blending, regenerate the missing heterocyst at the broken end when placed on agar (Fig. 1*B* and *C*). This is always preceded by growth, however, which is found to be inversely related to the initial length of the fragment. A fragment with single heterocyst and initial length of 42.8 μm, increased to 142.8 μm (2.38 times), and another with an initial length of 100 μm grew to 157 μm (1.75 times) before the second heterocyst developed. The interheterocyst distance in 52 cases (total 100) was 141–150 μm and in 74 cases 131–160 μm, with an average value of 145 μm as the minimum length needed for the regeneration of the second heterocyst.

When fragments with no heterocysts attached to them were plated on agar plates they invariably regenerated one heterocyst first before further growth and the formation of the second heterocyst. The amount of growth preceding the formation of first heterocyst is variable and is not always related to their initial length but seems to depend largely on their location on the intact filament from which they were derived. The second heterocyst, however, generally formed when the average length of the fragment attained a range of 141–150 μm.

When the alga was grown on combined nitrogen, ammonium chloride or ammonium phosphate, the filaments were free of heterocysts because, as in *Anabaena*, combined nitrogen inhibited their formation. If the filament fragments were taken from such cultures, the first heterocyst appeared in them after a prolonged growth on nitrogen-free medium, more than what was needed for a fragment previously grown on medium free of combined nitrogen (Table 1).

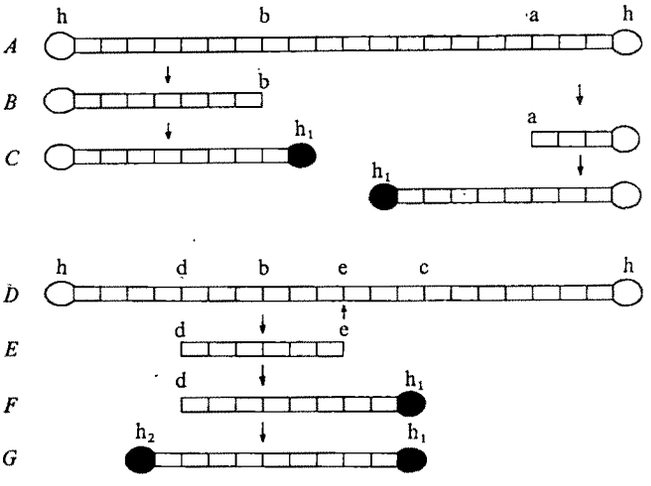

Fig. 1 Diagrammatic representation of a filament of *Cylindrospermum* showing the position of heterocysts (h) and the regeneration of new heterocysts (h_1,h_2) in the fragments. *A–G*, explanation in text.

If heterocysts do produce an inhibitor that controls the formation of other heterocysts, its concentration in a vegetative cell would be proportional to its distance from the existing heterocyst. Accordingly, the end of the longer fragment which is farther from the heterocyst develops another heterocyst more quickly (after growth) than the one in a shorter fragment. The fragment must grow before the formation of a second heterocyst to reduce the level of the inhibitor.

Heterocyst formation in fragments which do not already contain them (Fig. 1*E*), is very different, however. Such fragments can arise from any portion of the intact filament (Fig. 1*D*), either from the middle portions or eccentrically from one side (Fig. 1*D*, b-c, d-e). The fragment b-c may contain the inhibitor at equal concentrations at both ends and when heterocysts develop they may arise simultaneously after a limited growth. On the other hand, in the fragment d-e, the inhibitor level would be greater at d than at e (as d is nearer to a heterocyst) and as a result the fragment

develops a heterocyst first at e and later at d, only when growth has taken place to reduce the inhibitor to a sufficiently low level.

During our work, we found very few cases where the heterocysts formed simultaneously in a fragment. In general, it seems that in *Cylindrospermum*, filaments do not easily break from the middle region and that almost all fragments arise eccentrically on either side of a mid point between the two terminal heterocysts. The successive formation of heterocysts in a fragment containing no heterocysts is also an indication of the existence of polarity in the filament of the alga, which is itself a reflection of a gradient in the level of the inhibitor. A normal filament may have a decreasing gradient of the inhibitor starting from the terminal heterocyst to the mid point of the filament, the other half of the filament being a mirror image of this.

When fragments of *Cylindrospermum* were taken from the alga previously grown in a medium containing combined nitrogen and plated on agar medium free of ammonia, they were found to regenerate their first heterocyst only after a prolonged time, during which greater growth has taken place in them compared with the fragments grown earlier on molecular nitrogen. Presumably, by growing on combined nitrogen, the internal level of the inhibitor remained at a high level and as growth took place decreasing its concentration, the formation of heterocysts was initiated. The heterocysts appeared sequentially, however, first at one end and later at the other. This shows that the filaments whether grown on molecular nitrogen or combined nitrogen, still show polarity, that is their terminals are predetermined with regard to regeneration.

The nature of the inhibitor produced by heterocysts to control their spacing pattern is still debatable[1-5] but recent findings indicate that heterocysts are the site of nitrogen fixation[5]. Fogg's suggestion[6,7] that ammonia concentration in the filament is responsible for such an inhibition gains further ground, but it may not be the only deciding factor[1].

We have already discussed in some detail[8] how the spacing of heterocysts could be controlled in *Anabaena* in terms of the known metabolic activities of the heterocysts as well as the vegetative cells (see also, Wahal *et al.*[9] for the role of ascorbic acid). Although filament polarity is found in many blue-green algae, such as *Rivularia*, nothing is known of its nature and maintenance. In *Anabaena*, it has been shown[10] that cell division is asymmetrical and heterocyst spacing is controlled by the interaction between developing cells[11] but it is yet to be seen whether a similar situation exists in *Cylindrospermum* also.

This work was suported by a research grant from the Council of Scientific and Industrial Research, New Delhi.

GENERAL

Commercial radionuclide dispensing

Commercial suppliers of radionuclides operate under stringent regulations. Most companies give specific assurances of nuclide identity and purity. Examples are the plots of γ spectra, radiochromatograms and, most important, the data sheet that specifies such things as quality, purity and radiation intensity of the specific nuclide. Unfortunately, however, the controls used by suppliers are inadequate and the technical data sheet cannot be relied upon implicity.

In support of other reports[1-3] I shall relate an experience which involved a shipment of radioiron. On arrival, the package was monitored and the γ activity was about 10% of that expected. The supplier confirmed this and explained that a technician had calculated the stock to be 28.7 mCi ml^{-1} instead of 2.87 mCi and ml^{-1} had therefore dispensed only 10% of the required volume. Despite the small volume, however, the radiation value show, on the technical data sheet was that expected for 2 mCi of ^{59}Fe (about 70 mr h^{-1}), which suggested that the number was either recalled from memory or copied from an old sheet. I stated this in a letter and the company responded with a written acknowledgment of error. The compounded errors, they explained, were because of rapid expansion and shortage of personnel. They believed that safeguards and routine controls, (which were not specified), would be effective in the future.

Eliminating the monitoring step and entering an assumed value for radiation were serious errors. Companies should enforce separate duties, so that a person who dispenses radionuclides cannot also perform assays, complete data sheets, package, monitor and authorise final release for shipment.

It seems reasonable, as a partial answer to this problem, that if readout plots of γ spectra or chromatograms of various nuclides can be supplied to customers, then automatic recordings of radiation could also be provided. Such records could be inspected by supervisors to detect nuclide deficiency or excess and then be duplicated to provide a customer copy. The production of an authentic radiation report for the sample would be of the greatest importance. This should help eliminate the temptation to take short cuts and to falsify reports with assumed radiation values.

book reviews

Lobotomy

Psychophysiology of the Frontal Lobes. Edited by K. H. Pribam and A. R. Luria. Pp. xii+332. (Academic: London, August, 1973.) $19.95.

THE starting point of interest in the frontal lobes was the celebrated "Crowbar Case" reported by Harlow in 1848. One Phineas Gage, a quarry worker, had a large iron tamping rod blown by a stick of dynamite into his jaw and and out through the top of his head, producing serious injury to both frontal lobes. As a result, Gage underwent a disastrous change of personality. From having been an efficient and capable foreman, he became fitful, irreverent and obstinate, and is said to have "indulged in profanity that would have embarrased an 18th century British Sea Captain". Thus was born the "frontal lobe syndrome", the study of which in modern times owes much to the Russian neuropsychologist Alexander Luria, himself a coeditor of this volume.

Although a subject of fascination to psychiatrists and others, the frontal lobes have hitherto excited comparatively little interest among physiologists, largely because they are in the main electrically inexcitable and their excision does not occasion gross defects in sensation or movement. Indeed it was not until systematic behaviour experiments were begun in the thirties that any appreciable progress was made. These experiments claimed to reveal some fairly constant behaviour deficits in subhuman primates following bilateral frontal excisions and also—incidentally—led Moniz to inaugurate the era of psychosurgery. Dr Karl Pribram, likewise a coeditor, has been active over many years in charting the behavioural deficits produced in monkeys by circumscribed cerebral excisions. Their underlying physiology, however, has remained largely unexplored.

This volume represents an attempt, if a somewhat diffuse and ill-coordinated one, to fill this gap. Based upon a symposium on frontal lobe function held during the 18th International Congress of Psychology in Moscow some years ago, it brings together fourteen papers concerned with the neurophysiology of the frontal lobes and the effects of frontal lesions on the electrical activity of the human brain. Of the contributors, fourteen are American (mostly based on the West Coast), eight are Russian (all based on Moscow) and one is English (based on Bristol). The history of the enterprise and its relation to other recent symposia on closely related topics is outlined in a brief preface.

Taken as a whole, this volume reveals a distinct difference in approach as between the Russian and American contributors, though there is, of course, a good deal of common ground. By and large, the Russian work is almost exclusively limited to experiments with human subjects, mainly evoked potential and EEG studies, whereas the Americans give far more attention to the data of animal experiments and to explanation of behavioural deficits in physiological terms. Although much of the work is pretty specialised, it does serve to give an overview of current physiological work on the frontal lobes, though alas there is nowhere any real sign of a breakthrough.

In his concluding chapter, Pribram discusses frontal lobe functions in terms of spatial and temporal organisation and, more interestingly, the inhibitory mechanisms that, when deranged, produce the distractibility so marked in the 'frontal' animal or patient. He also places stress on the frontal cortex as the "executive" of the brain in the overall control of behaviour. In this latter claim, at least, he and Luria see eye to eye.

O. L. ZANGWILL

Breaking bones

Mechanical Properties of Bone. By F. Gaynor Evans. Pp. xiii+322. (Thomas: Springfield, Illinois, June 1973.) $25.75.

THIS interesting and well illustrated compendium of data on the mechanical properties of bone is a necessary reference work for all biologists and engineers who are concerned with the mechanical properties of materials. For the biologist, and this includes the orthopaedic surgeon, neurosurgeon, orthodontist and others who must be particularly interested in the effects of force either applied to, or generated within the body, an understanding of the mechanical properties of bone, which forms some 18% of the body, is essential for the prevention and treatment of a variety of conditions afflicting the musculo-skeletal system. An assessment of the change in mechanical properties of biopsy specimens of bone in the course of disease and its treatment may before long become a diagnostic and prognostic procedure.

For the engineer an appreciation of the design of the skeleton, the structure of bone and its mechanical properties is of considerable interest. In particular the materials scientists and structural engineers who are concerned with the design of passenger-carrying vehicles, which are increasingly involved in accidents, need the information concerning the mechanical properties of the living item contained within the vehicle. This book deals with, in the main, the mechanical properties of bone as a material. The thoughts of those who are responsible for the development of new materials may well be stimulated by the section dealing with the effects of the microscopic structure of bone when considered as a structural material.

For those who are interested in the mechanical properties of the whole bone this work should be read in conjunction with the author's other publication *Stress and Strain in Bones.*

JOHN T. SCALES

Water crossing membranes

Water Transport in Cells and Tissues. By C. R. House. Pp. vi+562. (Monographs of the Physiological Society, No. 24 Arnold: London, January 17 1974) £10.50.

THIS book is a mine of information and the fact that more than 900 references are included in the bibliography is a measure of the thoroughness with which the relevant literature has been surveyed. Of the total of ten chapters, seven make unexceptionable reading and the accounts of transcapillary and transepithelial water transport are outstandingly clear and comprehensive. The permeability characteristics of cell membranes in general and of artificial membranes also receive detailed and informative consideration as do the physical and chemical properties of water, which are dealt with at the beginning of the book.

The account of fluid dynamics in the embryo is less impressive, although this seems to be due more to the shortage of precise information than to any fault of the author, who is led to the conclusion that "our ignorance of the processes that trigger, enhance and finally block the formation of extra-embryonic cavities is enormous". One may question the wisdom of devoting nearly 25 pages to the exposition of this topic, except perhaps as a challenge to future investigators, to whom the message could have been given rather more

succinctly. On the other hand, the treatment of water movement in plants is somewhat skimped and includes virtually no discussion of transport in the xylem. I was particularly disappointed to find no reference to the extraordinary ability of the giant Redwood trees to raise water.

The author in his preface refers to the dilemma which faced him in deciding upon the place of mathematical theory in his book, a dilemma which he resolved by introducing a short "practical preamble" at the beginning of his chapter entitled "Phenomenological Description of the Transport Process", and then following this with a fairly lengthy excursion into irreversible thermodynamics. For the *cognoscente* this excursion is probably unnecessary; the presentation is too compressed to be really helpful to the novice and does not bring out at all clearly the thinking behind the development of irreversible thermodynamics from its more familiar progenitor, equilibrium thermodynamics, sometimes dubbed "thermostatics". These are contrasted in terms of entropy changes rather than of the notion of moving from states to rates. But the mathematics used is relatively straightforward and furthermore, the succeeding parts of the book can be read profitably without any particular mathematical expertise.

LOW TEMPERATURE LABORATORY TECHNIQUES

A. C. Rose-Innes

In the last ten years, since the publication of *Low Temperature Techniques*, there have been considerable advances in this field. So much so that in bringing the material up to date a new book emerged with the more suitable title of *Low Temperature Laboratory Techniques*. The book has been divided into two parts. Part 1 deals with the use of liquid helium^4 to obtain temperatures down to about 1K and describes the techniques and apparatus which can be used. Part 2 deals with the use of liquid helium^3 to obtain temperatures below 1K and will be most useful to engineers and scientists who use very low temperatures in their research.

THE ENGLISH UNIVERSITIES PRESS

Dept P868 St. Paul's House
Warwick Lane, London, EC4P 4AH

Dr House's approach to his subject is commendably judicial and the evidence for and against the ideas which he discusses is carefully evaluated and, where appropriate, he has interposed a a 'summing up'. Occasionally he abandons his detachment and confesses, with engaging candour, to personal bias. For example, this bias is freely admitted following a spirited and critical examination of the widely accepted dogma that active transport of water is inadmissible on energetic grounds. A plausible, if slightly confusing case, based as it is on a mixture of reversible and irreversible thermodynamics, is put forward for bringing in a verdict of "not proven" on this highly controversial issue.

This monograph forms a worthy addition to the series published for the Physiological Society. To predict that it will successfully stand comparison with some of the best of its predecessors implies both an established criterion for judgement and at the same time a deserved compliment to Dr House.

R. V. Coxon

Warm blooded

Temperature Regulation in Mammals and other Vertebrates. By John Bligh. Pp. xix+436. (North-Holland: Amsterdam and London; American Elsevier, New York, 1973.) $30.20.

Dr Bligh is to be congratulated on writing a book which is stimulating and concise, covering the whole field of thermoregulation in vertebrates—an area in which he himself is a distinguished worker. The book is written from the physiological standpoint and it will prove unsatisfying to physiological ecologists, since, for instance, many of the adaptations shown by mammals living in unusual environments are mentioned only briefly or not at all. It includes chapters on the traditional areas of thermoregulation (central control, sensing systems, effector mechanisms, neuronal influences, central transmitter substances and so on).

There are very stimulating chapters on the various models of the thermoregulation system which have been proposed, and there are useful sections on unorthodox theories, fever and exercise. In the section on comparative thermoregulation there seems to be no mention of the recent work on thermoregulation in certain large fish. This, however, does not take away from the overall high standard of the book which is highly recommended. It is a well produced book but perhaps rather expensive.

J. N. R. Grainger

Scientific literature

Understanding Scientific Literature: a Bibliometric Approach. By Joseph C. Donohue. Pp. xiii+101. (MIT: Cambridge, Mass. and London, 1973.) $10.

Twenty years ago, the American librarian Jesse Shera was advocating the study of a 'social epistemology' defined as "the analysis of the production, distribution and utilisation of intellectual products in much the same fashion as that in which the production, distribution and utilisation of material products have long been investigated". He pointed out that all the requisite data are to be found in the books and journals that fill the shelves of our libraries. By analogy with econometrics the term bibliometrics was later coined to cover the essentially data-collecting and analytical phase of a more theoretical study, which would be concerned with the organisation of mankind's exosomatic stores of knowledge for more effective social use.

In an uncoordinated way the statistical analyses Shera called for have been developed in recent years and the slim volume under review is the first monograph wholly devoted to these matters. One would expect the author of such a work to offer a critical review and constructive coordination of the widely scattered contributions and thus present the first consolidation of the emergent study. The need for such a work is now more urgent than it was twenty years ago because during that time large-scale computerised documentary information systems have been developed and the feasibility of even larger world systems is now being discussed. But all systems so far designed have been based on the very questionable assumptions that all published scientific papers have equal scientific weight, that 100% coverage is a desirable goal and that all papers retain their scientific interest *sine die*. These systems can only become more effective, more frequently used and less costly when their designers pay attention to the use made of scientific information by its scientific users—a use which is fully documented within the scientific journals themselves.

There are several techniques which bear on these matters and which one would expect to find described in a 10-dollar monograph. Two empirical laws have been known for some time. In 1925, Lotka noted that the number of authors who contribute r papers to any specified subject literature over any specified period is proportional to $1/r^2$ (though the exponent is 1.89 rather than 2). And in 1934, Bradford noted that, when bibliographical sources are ranked in order of decreasing productivity, the number of items contributed

by the source of rank r is proportional to $1/r$ if r is greater than a certain limit—an empirical law which applies to many other social contexts. More recently, Goffman has shown that the dissemination of new ideas is closely analogous to the spread of infectious diseases with endemic outbreaks preceding the take-off to epidemic growth. He has considered the conditions that have to be satisfied before take-off can occur and also the conditions under which scientific communication begins. to break down under the weight of its own documentation.

It has also been noted that scientific literatures not only grow at different exponential rates but decay exponentially at comparable rates, with half-lives of four to 16 years, so that the 'information explosion' worries only those who wish to keep everything—alive or dead. Work has also been done, mainly in the United States, on 'bibliographic coupling'—a technique of tracing who cites whom to identify networks of scientific interaction. There is therefore a varied and comprehensive task to be done by the author of the first monograph describing these techniques and their applications to information system economy.

Unfortunately, a great opportunity has been missed. The author makes a personal selection from the techniques. He inadequately and uncritically discusses only the Bradford law, the epidemiological model and some cross-citation techniques. He makes idiosyncratic selections of illustrative material drawn wholly from American sources and bibliographically ill defined. The numerical conclusions and graphs are firmly expressed though they are based on modest samples with no intimation that sampling errors might arise. The 100-page monograph reduces to 70 pages of text and 30 pages of singularly uninformative graphs. Thus the price of this modest introductory essay of 20,000 words is highly inflationary.

B. C. Brookes

Neutron generators

Activation Analysis with Neutron Generators. By Sam S. Nargolwalla and Edwin P. Przybylowicz. Pp.xvii+662. (Chemical Analysis: A Series of Monographs on Analytical Chemistry and Its Applications.) (Wiley Interscience: New York and London, January 1974.) £16.25.

It is often very important to be able to take one's microanalytical kit with one around the Universe. This has not been easy with neutron activation analysis, since fission reactors are heavy and one does not take them easily down a mine or to the moons of Jupiter. But small generators of fusion neutrons (say using the D-T reaction) can be made, although they have some problems such as the stability of their neutron yield.

This book attempts to summarise the uses of generators and can be described as "nearly a handbook" on the subject. A handbook normally leads you through mazes of research material easily, smoothing out the little wrinkles in the patchwork of data. In parts of this book, I feel the authors have indeed essayed such a task of inspection of pedigree and smoothing of data. In others, the reader is not sure whether a table of figures on, say, a type of neutron reaction is raw from one man's research or represents the sum of knowledge. The intent of many of these tabulations, which could have been properly signalled in only a few words, is sometimes left unclear. Thus, this book is perhaps best described as a research review which nearly achieves handbook status.

The authors certainly attempt completeness of coverage; they have used the prodigious documentation services of the US National Bureau of Standards (NBS) at which institution they once worked together, to compile the knowledge of the bureau and others on the use of neutron generators and the course of nuclear reactions activated by fusion neutrons.

The techniques for the generation of neutrons and the exposure of samples are lovingly described, with detailed engineering drawings and dosimetric maps. A section follows on the treatment of the diverse types of systematic error which can interfere with the analytical accuracy of the method and this section certainly convinces that, for certain important elements, neutron activation can surpass X-ray fluorescence or atomic absorption methods. It is, however, this first half of the book, which is somewhat littered with tables of doubtful intent, that will neither help the student nor satisfy the man in search of a handbook; by contrast, the second half of the book consists of a 300-page chapter that takes in turn each element which will succumb to activation analysis. The authors tabulate the nuclear reactions which work with fast neutrons, and then give for each a set of comments and data useful to the analyst, including a uniform set of computer-generated curves for buildup of radioisotope against time, decay against time and so on. Here, the reader's confidence in completeness and uniformity can be high. Finally, there are several appendices giving tabulations, by other workers, of those nuclear reactions which are useful in analysis. These are doubtless useful to have to hand but are, again, insufficiently clear in intent.

The impression left is that neutron activation analysis is a formidable subject to venture into unless armed with much knowledge and time. This is not the expressed intention of the authors, who wish to stimulate the broader use of the method and fairly state the advantages and disadvantages of the method compared with those of the rival techniques. They have certainly done a great service in dragging out and starting to organise the files of the NBS on this subject: however, it will take a firmer hand to encourage the hesitant to embark on this technique or to construct a true handbook out of all that information. On the other hand, a scientist already committed will learn all about the special techniques needed to maintain analytical accuracy and all the rest of the practical issues in this undoubtedly useful field of work.

A. G. Holmes-Siedle

Stars for students

Introduction to Stellar Atmospheres and Interiors. By Eva Novotny. Pp. xii+543. (Oxford University: London and New York, September 1973.) £7.00.

This book is intended as a textbook for senior undergraduates and commencing graduate students. It is a generally well written and well produced book but in my opinion the balance of the book is wrong for a textbook. The basic concepts of the subject tend to be described very briefly and important fundamental results are often quoted without proof, whereas many pages of tables and diagrams are devoted to the detailed results of particular solutions of the equations of stellar structure and evolution.

Two examples will serve to illustrate what I mean. About fifteen pages are devoted to tables of the monochromatic absorption coefficient in stellar atmospheres and a further ten pages to tables of the properties of model stellar atmospheres, but there is no detailed discussion of the form of the equations which must be solved to obtain a model stellar atmosphere, except in the case of a grey atmosphere in local thermodynamic equilibrium. It is mentioned that there is a maximum mass for white dwarf stars and a reference is given to where a physical explanation of the existence of a maximum mass can be found. The book would have been much improved if one page of tables had been sacrificed so that a brief explanation of the existence of the maximum masses of cold bodies of various types and of the near inevitability of the existence of black holes could have been included.

One danger of including too many

Plant Cell Structure and Metabolism

J L Hall, T J Flowers and R M Roberts.

An up-to-date treatment of plant metabolism in relation to cell structure. Current knowledge of the plant cell is frequently reviewed in the light of what is known about mammalian or microbial systems, particularly for the areas where plant science is not so far advanced.
The text assumes a basic knowledge of chemistry and biology and is suitable for undergraduate students of plant and biological sciences, postgraduate students of plant biochemistry and physiology

£4.95 net.

East African Vegetation

E M Lind and M E S Morrison

This book describes the major types of vegetation to be found in Uganda, Kenya and Tanzania. These are dealt with under the main headings of forests, rangelands, inland aquatic vegetation; the vegetation of the sea coast, high mountain vegetation, the factors affecting vegetation, climate and soils, and a short history of the vegetation of the region.

£6.00 net.

Longman 1724-1974

detailed results in a first textbook is that they may be regarded as being more reliable than they really are. Although in some cases it is made clear that the results quoted only represent one point of view, this is not always true. In the discussion of the evolution of stars approaching the main sequence, the Hayashi theory is fully tabulated but no mention is made of the later work by Larson which casts considerable doubt on the previous results.

More detailed criticisms of the book include the feeling that far too much space is devoted to the Vogt Russell theorem which is certainly not generally true and that the concepts of thermodynamic equilibrium and local thermodynamic equilibrium should have been described much more clearly. It is also a pity that the discussion of numerical methods does not include the Henyey technique, which has been most widely used in recent years.

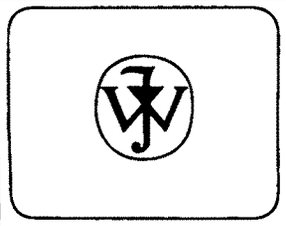
Now that I possess the book I may well find it very useful to have in one volume so many tables and figures illustrating recent studies of stellar structure and evolution and students will similarly be able to use it as a reference book. But it seems very unlikely that for students it will replace such texts as that by Schwarzschild, which is considerably cheaper and which gives a much deeper physical understanding of the subject.

R. J. TAYLER

Magnetic rocks

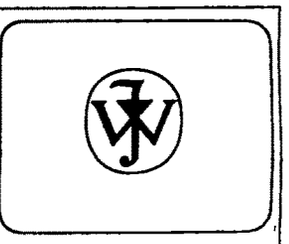
The Physical Principle of Rock Magnetism. By Frank D. Stacey and Subir K. Banerjee. Pp. ix+195. (Developments in Solid Earth Geophysics, Vol. 5.) (Elsevier: Amsterdam, London and New York, 1974.) Dfl.60; $2.10.

THIS book was advertised for over a year before its appearance, but it has been worth waiting. It is a slim volume deliberately planned as a physical supplement to Irving's *Palaeomagnetism and its Application to Geological and Geophysical Problems* (Wiley, 1964). It must also be considered to effectively replace Nagata's excellent, but outdated book, *Rock Magnetism* (Maruzen, 1961) although it does not contain any instrumental discussion that formed a significant part of Nagata's work.



The organisation is logical, starting with the basic magnetic properties of solids and then turning to the common ferromagnetic minerals, magnetite and haematite and their solid solutions with ilmenite and ulvospinel. This chapter certainly brings the reader up to date on the current view of the changes in parameters for synthetic solid solutions and pure minerals, but more information on the effects of impurities would have been useful. Only the two pages on pyrrhotite are not really adequate for a mineral that is extremely complex and not all that rare. Single and multi-domain theories are considered next, first in relation to grains of magnetite and then haematite. The outline and discussion tends to follow closely Stacey's ideas, originally published in 1963, as does the subsequent treatment of the effects of time and temperature.

The next chapter is devoted to the remanence of sediments and is followed by a discussion of chemical remanence that is largely confined to exsolution behaviour as titanomagnetite solid solutions are oxidised. The effect of anhysteritic magnetisation and stress fields then receive considerable, warranted attention. The latter is, however, concerned almost entirely with stress effects on the direction of remanence and does not consider the converse, that is using magnetic anisotropy as a means of determining strain and hence evaluating past stress fields. The evidence for reversals of the geomagnetic field and possible self-reversal mechanisms are considered in rather a generalised way; the correlation between petrology and polarity that has been established in some regions is dismissed as being "paradoxical" in only four lines.



Finally extraterrestrial magnetisation is discussed and the remanence of meteorites is attributed to strong solar fields when the Sun passed through a T-Tauri stage. Strangely no mention is made of the magnetic properties of lunar rocks—presumably to avoid being overtaken by more recent findings.

The book is well written, adequately illustrated and its production is up to the usual high Elsevier standard. The only significant weakness is really in terms of the magnetisation of sedimentary rocks which are discussed in less than 5% of the total book, yet more and more sedimentary rock types are now being investigated and the magnetic effects during cementation and the diagenetic changes of detrital grains are much more important than simple detrital magnetisation. A little more on rotational hysteresis and physical techniques for identifying both the composition and physical parameters of ferromagnetic particles in rocks would have been beneficial. The bibliography is really a reference list that effectively only goes up to 1971 (only six references for 1972 with one "in press" and one "in preparation" for 1973). The authors defend their continued use of c.g.s. units, although the use of MKS can only come about when the textbooks adopt the system. These, however, are essentially quibbles about a book which must form part of any geophysics library.

D. H. TARLING

WILEY INTERSCIENCE

PATHOLOGIA EUROPAEA
International Journal of Experimental and Cellular Pathology

Editor-in-Chief
P. Dustin,
School of Medicine, University of Brussels
Co-Editor
R. Masure,
University of Louvain

This entrenched and authoritative journal is the official organ of the European Society of Pathology and is being published by Wiley from 1974. It is truly international and gives a wide coverage of recent developments in pathological sciences, where new techniques are integrating clinical and experimental studies with cell biology, molecular biology and ultrastructure research.

One of the principal aims of the European Society of Pathology, founded in Salzburg in 1964, is to increase the links between European pathologists and promote the development of pathology in its widest sense. It was felt by the Founder Members of PATHOLOGIA EUROPAEA that the rapid growth of the pathological sciences, both experimental and descriptive, and the need for better coordination in European research, warranted the creation of a new international periodical, *open to pathologists of all countries and in all fields of research.*

Subscription price for 1974:
£15.00 per volume (4 issues)

International Journal of CHRONOBIOLOGY

Editors:
Franz Halberg, *Chronobiology Laboratories, Department of Pathology, University of Minnesota*
Alain Reinberg, *Foundation A. de Rothschild, Laboratoire de Physiologie, Paris*
Hugh Simpson (Executive Editor)
University Department of Pathology, Royal Infirmary, Glasgow

This remarkable journal already in existence for more than a year is probably still ahead of its time! Publishing papers on all aspects of the subject popularly known as 'Biological Rhythms', it provides a platform for this fast developing branch of science, where so many exciting discoveries are being made.

Chronobiology is the science of quantified and predictable temporal biophenomena including biological rhythms, developmental changes and ageing.

The separate identity of chronobiology as a science rests on three main points.

1. It has a clearly defined aim i.e. an evaluation of the anatomy-in-time of living material.
2. It has an original objective statistical methodology.
3. It has a rapidly broadening base of facts.

Subscription prices for 1973/1974:
£13.00 per volume (4 issues)

ADDICTIVE DISEASES
An International Journal

Edited by **Carl D. Chambers**
Clinical Professor in Psychiatry, University of Miami, School of Medicine

This is a new quarterly journal published by **Spectrum Publications Inc.** and distributed in the U.K. and Europe by Wiley.

Addictive Diseases is a totally new publication designed to assist all health and other involved professionals in the understanding of the phenomena generally grouped within the category of addictive diseases. It thus, includes both drugs and alcohol.

Addictive Diseases is international in scope with an Editorial Board selected specifically to attract contributions from pre-eminent scientists and practitioners wherever they do their work. The Editor and the Editorial Board will invite relevant papers, rather than wait for any 'natural flow'. To this end, the Editorial Board represents a wide number of sub-specialities within the area.

Theoretical as well as empirical papers are being presented, as are research contributions from the many social-behavioral and biochemical-pharmacological disciplines. It has known priorities: e.g., innovative treatment and treatment evaluation studies enjoy a higher priority than straight demographic or descriptive studies of using populations.

First issue March 1974
Subscription Price for 1974:
£14.00 per volume (four issues)

Chemotaxonomy of Flowering Plants

by R. Darnley Gibbs

This outstanding work, consisting of four volumes and about 2,500 pages, will be published on June 28, 1974. Before that date it may be ordered at the special price of $110.00. Thereafter, it will be available at the regular price of $135.00.

Among its important features are listings of plant constituents and their known distributions; the most complete and accurate listings yet produced of families of dicotyledons and monocotyledons, with original citations and taxonomy; listings and taxonomic notes on virtually all the proposed orders; a bibliography of more than 1,000 entries; many figures and tables; and a comprehensive index.

CHEMOTAXONOMY OF FLOWERING PLANTS is the result of nearly thirty years of study, research, and compilation and will be the definitive work for many years to come as:
—a unique reference to what is known in this field up to the present time, and
—a major source of ideas for research in the future.
It will be indispensable to plant systematists, botanists, chemists, and all others teaching and researching in related fields.

To order, or, for further information, please write to: McGill-Queen's University Press, 1020 Pine Avenue West, Montreal, Quebec H3A 1A2, Canada.

Molecular Biology comes of age

This special **Nature** Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, **'Molecular Biology Comes of Age'** looks back on the circumstances surrounding the original appearance in **Nature** of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'Molecular Biology Comes of Age' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of **'Molecular Biology Comes of Age'** are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

Circulation Department, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me ..... copies of **'Molecular Biology Comes of Age'**, by surface mail/airmail (delete whichever is not applicable).

THE USE OF GENETICS IN INSECT CONTROL

edited by R. PAL, *Vector Biology and Control, World Health Organization, Geneva, Switzerland, and* M. J. WHITTEN, *Division of Entomology, CSIRO, Canberra, Australia.*

1974, 254 pages, Dfl. 80.00 (about US$30.80)
ISBN 0-7204-4145-5

The use of insects to limit reproduction and survival of their own species in natural populations adds a new dimension to the concepts of managing pest populations. This autocidal method, involving the release of sterilized or genetically altered insects, should be particularly useful as a component of various integrated systems for the control of major pests. It provides a highly selective method of insect control that is of major significance today because of growing concern for the maintenance of environmental quality.

This book is based on papers originally presented at a symposium held at the 14th International Congress of Entomology, Canberra, Australia, 1972.
These were rewritten and edited to produce a balanced and up-to-date evaluation of the state of the science.

Contents: 1. Introduction *(R. Pal and M. J. Whitten).* **Part I: Insects of Agricultural Importance.** 2. The development of genetic methods of controlling the Australian sheep blowfly, *Lucilia cuprina (G. G. Foster and M. J. Whitten).* 3. Genetic control of spider mites *(W. P. J. Overmeer).* 4. A genetic approach to the population suppression of the common field cricket *Teleorgryllus commodus (T. W. Hogan)* **Part II: Insects of Public Health Importance.** 5. WHO/ICMR programme of genetic control of mosquitos in India *(R. Pal).* 6. Incompatibility in *Culex pipiens (A. R. Barr and J. H. Yen).* 7. The current status of genetic methods for controlling *Aedes aegypti (K. S. Rai, N. Lorimer and E. Hallinan).* 8. Genetic studies on *Culex tritaeniorhynchus (R. H. Baker and R. K. Sakai).* 9. The present status of genetic control mechanisms in the house fly, *Musca domestica L. (D. E. Wagoner, I. C. McDonald and D. Childress).* **Part III: General.** 10. Ecology and sterile release programs, the measurement of relevant population processes before and during release the assessment of results *(M. D. Proverbs).* 11. The future of chemical sterilants in entomology, their use against insect populations in the field and their mammalian toxicity and hazards *(F. J. D. McDonald).*

Pharmacia Gel Electrophoresis System

for polyacrylamide gradient electrophoresis and other P.A.G.E. techniques

The complete system
Full capabilities for the new pore gradient electrophoresis technique, two dimensional studies, gel rod electrophoresis.

Polyacrylamide gradient gels PAA 4/30
Convenient ready-to-use gradient gel slabs give extreme resolution over the whole range 50,000–2 million MW. Self-limiting migration concentrates the zones after separation by molecular size.

Gel electrophoresis apparatus GE-4
4 gel slabs, 12 samples on each, or 16 gel rod capacity. Robust moulded construction with built-in cooling system. Full range of accessories for all applications.

Electrophoresis power supply EPS 500/400
Compact, all solid state. 0–400 mA constant current, 0–500 V constant voltage with automatic cross-over. Maximum effect 60 W. Full personnel and instrument protection. Available 1974.

Gel destainer GD-4
Electrophoretic or diffusion destaining of slabs or rods in a single operation. Twin cells. Active dye removal and solvent circulation. Results can be inspected at any time.

Destainer power supply DPS
Compact, reliable, all solid state. Push-button selected constant voltages 12, 24, or 36 V. Timer controls electrophoretic destaining up to 90 minutes.

Find out more about the Pharmacia Gel Electrophoresis System from your usual supplier of Sephadex® and Sepharose®.

Pharmacia Fine Chemicals

Guide to authors

Nature accepts three types of communications:

● Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

● Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

● 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (*a*) is preferred to e^a if '*a*' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Possible role for the Fc receptor on B lymphocytes—*R. Ramasamy, A. Munro and C. Milstein* 573

NATO Advanced Study Institutes Series

Series B - Physics

The NATO Advanced Study Institutes, renowned for their incisive analysis of high-level research in important new fields, host hundreds of successful gatherings which bring together the best minds from the international scientific community. In cooperation with the NATO Scientific Affairs Division, this series offers reports of these meetings on the latest advances in physics. A companion series will present reports from the life sciences.

Problem-solving PhDs

ALTHOUGH the disillusionment of industry with at least some aspects of the present PhD system has been highlighted this year by the report of the House of Commons Expenditure Committee on postgraduate education, declarations on the need for change were made by academics and industrialists on the Swann Committee as long ago as 1968. That committee looked into the whole question of the flow of qualified personnel into employment and roundly stated that the universities should "experiment boldly" with the PhD and with the regulations governing its award.

Academics protest, quite rightly, that the PhD is not only a training in methods of research but also a means of preserving the continuity of university research—the aim of which is to generate new knowledge. That said, the question is whether too many 'conventional' PhDs are being produced. The fact is that of some 4,600 scientists graduating with higher degrees in 1971, some 1,200 took up employment outside teaching and lecturing, and although many of these had master's degrees a substantial number had doctorates. It seems logical therefore that some PhD students should carry out postgraduate work that will fit them for their eventual career in industry.

Changes along these lines have already been made by the Science Research Council (SRC). First, it has been running the so-called CASE scheme (Co-operative Awards in Science and Engineering). In 1972, 191 of these awards were made, out of a total of 2,220 new SRC research studentships. The SRC also offers postgraduate studentships to people who wish to do a postgraduate course after a spell in, for example, industry or teaching; 313 of these were taken up in 1972, for both research leading to a PhD and for advanced courses.

Like all collaborative schemes CASE has not been without its problems. The scheme requires joint supervision of the student by a member of the staff of the university concerned and a person from the collaborating institution, which following a relaxation in the rules may be a body like a hospital board or a local authority rather than specifically an industrial company. Trouble has arisen because the projects to be tackled have in some cases been badly or vaguely specified and often because of a lack of mutual understanding between the industrialist and the academic.

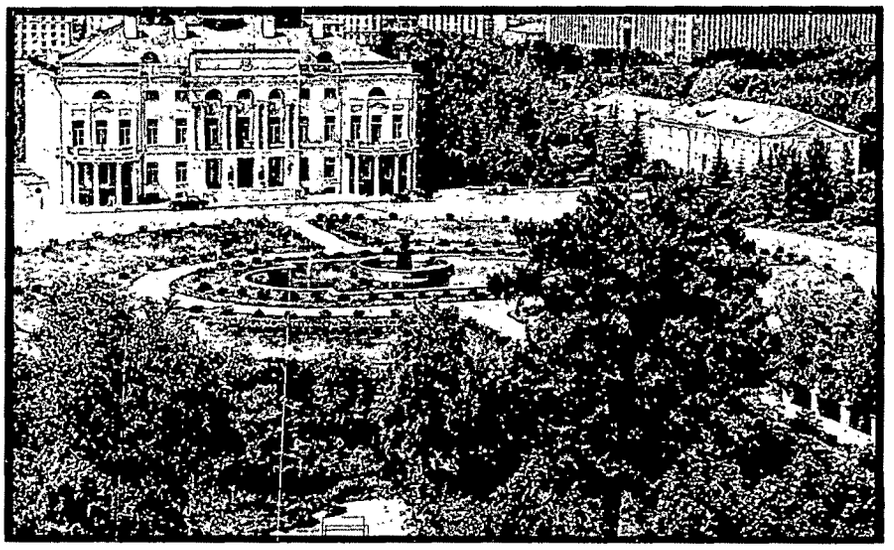
Yet another kind of doctorate that has emerged in the past few years is the interdisciplinary PhD. The idea arose from the discussions following the publication of the Swann report and involves a graduate, often, though not necessarily, a scientist, getting to grips with a real industrial problem which calls for an appreciation of economics, industrial relations and the like. The SRC and the Social Science Research Council jointly fund almost 100 interdisciplinary research studentships, about 30 of which are held at the University of Aston.

The University of Aston is also in the throes of preparing for the advent of "total technology" PhD courses. These are specifically for engineers and have many of the characteristics of the interdisciplinary higher degree scheme but with more formal course work. What the research student is required to do is to solve real engineering problems in a real company. The University of Aston is well placed to take advantage of this because it already has the central organisation that is required if projects for students are to be thought out properly before the student arrives. The SRC awarded the first six total technology studentships last year.

That is all very well, but what scope is there for the pure scientist who wants to do a 'nonconventional' PhD yet wants something different from the CASE scheme. One answer is that there should be more scope for research done in an industrial environment to form the basis of a university PhD thesis. Unfortunately some universities take the view that they are not in the business of externally examining for a PhD. They might do well to re-examine such an isolationist attitude.

Some may say that to extend the PhD concept too much is to reduce the degree to a certificate of ability to solve problems. But does this matter? Provided that those who are really cut out to do research in the true sense of the word still have a reasonable chance to do it the appearance of more doctors of problem solving (which is all some 'conventional' PhDs are at the moment anyway) seems to be much more of a benefit than a threat.

100 years ago



AN extract from a letter by Mr. Dunn, the geologist, now on a special exploring expedition to the Transvaal, published in the *Cape Argus* of May 5, gives a description of a thunder and hail-storm which he experienced at Pietermaritzburg, on April 17:—"Hail-stones, liberally mingled with great masses of ice of very irregular forms, poured down with great violence. The hail-stones were seldom less than 1 in. in diameter; the average was from 1½in. to 2 in. in diameter. These were of very regular spherical form, and consisted of a nucleus of white snow, with an envelope of hard transparent ice. Sometimes they presented, when broken through, a concentric arrangement of zones, alternately white and opaque and transparent. The irregular masses were formed of a nucleus generally longer in one direction than the others, from 2 in. to 4 in. in diameter; projecting all over were stalactites, each one about the thickness of a little finger, and presenting, when broken across, an agate-like structure, as though segregation had built them up. Of these masses I weighed a few with the following results:—Three weighed over 8 oz., two over 6 oz., and one over 4 oz. The mischief done will not be covered by 2,000*l.* or anything like that sum."

From *Nature*, 10, 115, June 11, 1874.

Russia's curtained window on the west

In the 250th anniversary year of the Russian Academy of Sciences, Vera Rich examines the rôle the Academy has played in international science.

The Academy's Moscow headquarters.

It can hardly be doubted that, in founding his Imperial Academy of Sciences, Peter the Great intended it to form one of the cornerstones of his Westernising policy—a consummation at the highest intellectual level of the European outlook that had driven him, earlier in his reign, to cut off his subjects' beards and to impose the death penalty on courtiers found sleeping with their boots on.

Yet Peter, who was personally curious about all branches of science and technology from the theory of navigation to do-it-yourself dentistry, having, after more than 20 years' cogitation, finally signed the decree "establishing" the Academy, on January 28, 1764, did not live to attend its opening. Exactly a year later, he died, succumbing to a chill caught, not in the pursuit of his innovations, but as a result of attending the traditional Epiphany Eve blessing of the waters! It was left to his widow and successor, the erstwhile illiterate Livonian peasant-girl, who reigned as Catherine I, to bring into being Peter's Academy, and it was on her nameday, December 27, 1725, that the inaugural meeting was held.

Although he is reputed never to have opened a book (and it must be said in passing that the improbably tall stories surrounding his name are more than legion), Peter seems to have been giving serious thought to the foundation of some eminent scientific body to grace his projected new capital and "window on the west" as early as the 1690s. During his visit to England in 1698, he visited the Royal Society (January 27), Greenwich Observatory (March 9) and Oxford (April 8) where he was presented with a number of mathematical books.

Back in Russia, he founded a Naval Academy, Artillery, Engineering and Medical Schools, and Russia's first national museum, the *Kunstkamera*, in his new capital of St Petersburg, together with several printing presses using the simplified typography, which he had introduced in 1708. He also began a prolonged correspondence with Leibniz, who had organised the Berlin Academy of Sciences in 1700, on the possibility of establishing a similar institution in St Petersburg. Although neither Peter nor Leibniz were to see the Academy come to fruition, nevertheless, in 1725 the first meeting finally occurred, and with a membership mainly of foreign, especially German savants.

This foreign, or rather, international, membership, persisted through the first difficult years of the Academy's existence (it had no official constitution until 1747, nor any established source of income). Prominent Academicians of that time include such eminent names as Nicholas (II) and Daniel Bernouilli (elected 1725), Leonard Euler (1727) and Georg Wilhelm Steller (of 'sea-cow' fame) (1737). It was from Euler's time at the Academy that the famous problem of the 'seven bridges'—one of the early landmarks of topology—dates. In spite of this source of inspiration, Euler found the atmosphere of St Petersburg unconducive to the free exchange of ideas, and in 1741 he accepted an invitation from Frederick the Great to join the Berlin Academy. (Asked by the Dowager Queen why he could only, apparently, speak in monosyllables, Euler is reported to have replied that "I've just come from a country where, if you speak, you're hanged!") In 1785, however, on the invitation of Catherine II, Euler returned to St Petersburg, where, in the intervals of research, he was expected to produce such diversions for the court as a formal mathematical refutation of the 'atheistic' views of the visiting French philosopher Diderot. (Euler's tongue-in-cheek "proof": "Sir, $(a+b^n)/n=x$, hence God exists; reply!", astounded the court, discomfited the unmathematical Diderot—and is reported to have found a place in current theological treatise!)

In spite of such Imperial digressions, the Academy at last settled down to producing its own scientists and scholars. Among numerous lesser luminaries, one finds names such as Lomonosov (elected 1741), Lenz (1828), Ostrogradskii (1828) and Krylov (of the *Fables* (1841).

There was still, however, a strong international atmosphere, reflected specially in the honorary members, who included Réaumur (1737), Voltaire (1778), Linné (1754), Boscovitch (1759), d'Alembert (1764), Diderot (a reward, maybe for valour?) (1773), Lagrange (1776), Bode (1794) and Kant (1794). British honorary members included such well-known figures as Maskelyne (1776), Priestley (1780), Sir Joseph Banks (1780), Malthus (1826), Sir William Parry (1826), Sir Humphrey Davy (1826) and Faraday (1830). In the eighteenth century, the United States was represented by honorary members Benjamin Franklin (1789) and John Churchman of Philadelphia (1795).

Yet in spite of its international beginnings, its use of Latin, French or German as its medium of publication (the *Comptes Rendus* of the Academy was still appearing in French in the 1940s), and the continuing election of foreign scientists as honorary members, the international contacts of the Academy did not proceed smoothly and unbrokenly. The early years of the nine-

Peter the Great: intended the Academy to form one of the cornerstones of his Westernising policy—a consummation at the highest intellectual level of the European outlook that had driven him to cut off his subjects' beards and to impose the death penalty on courtiers found sleeping with their boots on.

teenth century showed the Academy fallen on hard times. This was partly as a result of the foundation of new universities, so that the Academy lost a certain amount of prestige, being no longer the *ions et origo* of all learning in Russia, partly this was due to the conditions of the Napoleonic wars. Further, under Paul I (1796–1801), the receipt of literature from abroad was forbidden and international contacts were broken off. The membership of the Academy was reduced to half its original strength—and a large proportion of the remaining members were superannuated veterans, no longer able to attend meetings!

Paul's successor, Alexander I, was keenly interested in education, founding Universities (or reconstituting those, Vilna and Dorpat, which he had gained in recent territorial acquisitions). But although the Academy gradually regained its old strength and vigour, the vexed question of censorship remained. Knowledge might, and did, flow out of Russia—it was considerably more difficult for it to flow, or even to trickle in. The nineteenth century witnessed a running battle between the Academy and Universities on the one hand and the Government on the other, on the right of learned bodies to import foreign literature, especially periodical literature, without inspection by the censors. (It should be noted that censorship was, at times, ludicrously rigid; on one notable occasion a mathematical treatise was refused publication since it was feared that the " . . . " of the formulae for infinite series denoted a lacuna into which some revolutionary or otherwise treasonable matter would be inserted by dissident minds.) Although from the beginning, the Academy and Universities had been able to import scientific works (indeed, without them, no learned institution would have ever been able to begin functioning), the dispute arose out of the definition of "scientific". The new constitution of Vilna University (1803) implies that the Universities are to censor themselves. The decree on censorship of 1828 permitted the Universities and the Academy to "receive books without inspection by the censorship", but they are obliged "every time to inform the censorship committee for foreign books what the books are, how many, and when and by what route they were sent".

Although even the natural sciences (with their suspect symbolism) were not exempt from import difficulties, the problem was particularly pressing with the 'philosophers', who needed to read current political journals. The restrictions seem to have been imposed somewhat intermittently, according to the prevailing political atmosphere. Thus in the 1840s for example, the Academy was able to receive the *Allgemeine Zeitung* and *Berliner Nachrichten* fairly freely. A decree of 1860, however, imposes somewhat narrow limitations: "The Imperial Academy of Sciences, the Pulkova Observatory and the Universities may enjoy the right to obtain through the post from abroad books and periodical literature of academic content in an open wrapper, without extension of this right to members of the Academy and Universities." And since the opinion of the censorship on what was, and was not academic, was extremely arbitrary, one may find in these restrictions at least a partial explanation of the many claims that Russian scientists have discovered or elaborated some principle "independently" of work done abroad. Although most of the more fantastic claims disappeared with the excesses of the personality cult, one still finds from time to time references, for example, *Pravda*, June 12, 1973, to Popov as the inventor of radio. Such parallelism may be attributable, at least in part, to these censorship difficulties—a Russian working in a given field might well have been completely unaware of what his opposite numbers abroad were doing. Yet, conversely, certain eminent nineteenth century Russian scholars were never to become Academicians, Lobachevskii spent his life in the backwater of Kazan' and Mendeleev was refused membership on account of his dangerously 'liberal' views. One way and another, the nineteenth century Academy lost much by governmental intervention.

From the leisured days of the beginnings of the Academy (one eighteenth century silhouette shows an open air meeting reminiscent of a *fête champêtre* rather than a learned discourse) to the earnest days of post-Revolutionary Petrograd seems a far cry, yet, according to an official report of 1927, one of the first thing that the new régime did was to restore the old international contacts. "In the last ten years, the international relations of the Academy have taken the following forms: (1) participation of the Academy in permanent international unions and associations of general scientific interest or of special disciplines; (2) joint scientific enterprises, such as expeditions, publications, etc.; (3) participation of the Academy in International and other meetings and congresses convened

abroad, and in the anniversaries of learned societies, scientific institutions or individual scholars; (4) scientific missions abroad, including the permanent work of our scholars in laboratories of other countries; (5) rational and consistent exchange of scientific publications; (6) exchange of collections and the dispatch abroad, on a basis of reciprocity, of collections, manuscripts, and rare editions; (7) awarding of prizes and honorary titles to foreign scholars and mutual invitations to lecture at higher education institutions or to take part in conferences on particular occasions and, finally, rational organisation of the acquisition abroad of publications, instruments, apparatus and all other scientific material, necessary for the Academy and its institutions".

To what extent this excellent programme was implemented it is difficult to judge—official reports of this kind always have a tendency to overstate achievements. In any case, the picture was due to change. With the Stalinist purges of the 1930s, all contact with the West became not only discouraged—they were positively dangerous for those involved. Scientists who had trained abroad (under the plans so recently praised), were particularly vulnerable. In the Academies of the Union Republics (now virtually satellites of the All-Union Academy) where the accusation of 'nationalism' or 'separatism' was always possible, the situation was particularly tense. The Kiev Academy, for example, had no less than 13 Secretaries between 1921 and 1938, all of whom were, in turn, arrested. The election of foreign honorary members and corresponding members to the Academy came to a sudden halt. In the immediate post-revolutionary period, no foreign members were elected: then one member was elected in 1922, 18 in 1924 (including Frederick Soddy), one in 1925, one in 1926, five in 1927, four in 1928, nine in 1929, three in 1930, two in 1931, six in 1932, one in 1933, and in 1934, the year in which the Academy formally moved its headquarters (with 250 wagonloads of equipment and more than 300 scientists) to Moscow, time was still found to elect five new foreign members (of whom Max Born was one).

Then comes a complete gap. No further foreign honorary members or corresponding members were elected until 1942, when five new names (including J. B. S. Haldane) appear in the records, presumably as a symbol of Soviet friendship towards the Allies.

As for the work produced by the Academy during the 1930s, in spite of the new site, increased subsidies, the foundation of new institutes, and all other material government help that a learned institution might well desire, the growth of what was later to be known as the 'personality cult', was not conducive to sustained and concentrated research. As Robert Conquest has observed, although the man in the street could, in conditions of peril, stop talking, the professors and academicians had to go on lecturing! With the constant attrition due to the disappearance of those whose views failed to coincide with the current official line, and the occasional endorsement of a new theory from Party headquarters, Soviet science was not noted for the free dissemination of ideas. It became inward-looking, and self-congratulatory. When the 220th anniversary of the Academy was celebrated in 1945 (the 'Catherine' date being chosen, since on the 'Peter' date, the Soviet Union was fully involved with her war effort) we find in the proceedings of the occasion that the history of science has been considerably revised!

In aerodynamics, Mendeleev anticipated Prandtl's views on hydrodynamic friction by some 30 years, and a certain Rykachev in 1871 forestalled Eiffel's experiments on the lift of an airscrew by 40 years. The Danish Bering was no longer the discoverer of the Strait which bears his name—he merely confirmed the the discovery made by "the Cossack Deinev" in 1648. The forces of "chemical constitution" (the nature of the chemical bond) were investigated by Butlerov in 1862—although it is somewhat naively observed that as with many other Russian scientists, "his work was not always duly appreciated abroad!"

In the 1950s the Academy made a determined effort to free itself from the tight controls which demanded an immediate economic outcome of all projects, and, in spite of conventional lip-service to successive five-year plans, does manage to achieve a considerable amount of basic research that has little immediate connection with the needs of the economy.

On the international scene, however, all is not entirely well. International co-operation does take place—but with an increased emphasis on co-operation within the Comecon block or on aid to the developing science of the third world. Specific agreements for co-operation between the Soviet Union and a specific Western country on a specific project or set of projects only underline the lack of a general atmosphere of free exchange. Soviet scientific journals flow out freely to the West (and agreements have been made for the production abroad of cover-to-cover translations which appear within a few months of the Russian originals). But western journals entering the Soviet Union do so in single copies, which are then photocopied and distributed to academic institutions with any doubtful matter replaced by back-material of a more innocuous nature (for example, advertisements). The campaign of September 1973 against Academician Sakharov stated that "To be a Soviet scientist means to be a patriot"—one must not bite the Party hand that subsidises one's research, by advocating too close a co-operation with the west. The position of Jewish scientists who wish to emigrate to Israel who are refused a visa to emigrate, but at the same time dismissed from their posts so that they can no longer exercise the talents which the state is supposedly conserving for its own use has raised new and bitter feelings abroad.

The inaugural address of 1725 spoke of bringing Russia into the world scientific community. But, no reference was made to the fact that the Royal Society, so admired by Peter, specifically excluded all considerations of the religious or political views of its members—nor, would it seem, has the Academy yet learned, in the 250 years of its existence, to view a scholar's scientific achievements apart from his personal philosophy. The cancellation of the international celebrations of the anniversary of the Academy, and its replacements by a programme of popular scientific lectures to the grass-roots of Soviet Society—the workers and peasants, is more, therefore, than a gesture of pique over recent criticisms abroad of the restrictions and lack of academic freedom imposed on certain intellectuals in the Soviet Union—rather is it a repetition once more, of a pattern of isolationism which runs through the history of the Academy, a firm closing, yet again, of what was to have been one of the most prominent casements of Peter's "window on the west".

Charter of the Academy.

international news

Canada's reply to Indian nuclear explosion

David Spurgeon, Ottawa

CANADA has responded quickly and firmly to India's explosion of an underground nuclear device. External Affairs Minister Mitchell Sharp announced four days after the weekend's test that Canada has suspended all nuclear assistance and cooperation and recalled Atomic Energy of Canada Limited's resident representative.

Mr Sharp said that the Canadian government is very disturbed by the tests, in which a device of approximately 15 kilotons yield was reported to have been exploded at a depth of 100 metres. "For all intents and purposes", he told a press conference, "India now has developed the capability of producing a nuclear weapon".

Canada's concern has resulted from the likelihood that the plutonium used in the explosive device came from a reactor named CIRRUS that was a gift from Canada. Canada has also designed and helped to build and equip two electric power reactors at Rajasthan (Rapp I and Rapp II), and most of India's nuclear personnel have been trained in Canada.

Canada has long been fearful of India's nuclear intentions. Copies of correspondence between Prime Minister Pierre Trudeau and India's Prime Minister Indira Gandhi in October 1971, which were distributed at the press conference, reveal Canada's concern at that time for the prevention of proliferation of nuclear weapons.

"The use of Canadian supplied material, equipment and facilities in India, that is, at CIRRUS, Rapp I or Rapp II or fissile material from these reactors, for the development of a nuclear explosive device would inevitably call on our part for a reassessment of our nuclear cooperation arrangements with India, a position we would take with any other non-nuclear weapons state with which we had cooperation arrangements in the nuclear field", Mr Trudeau warned.

"My government", replied Mrs Gandhi, "reiterates its commitment to the provisions contained in the nuclear cooperation agreements between India and Canada to which your government is also committed. Our two governments have acted in conformity with these arrangements for the past several years. The obligations undertaken by our two governments are mutual and they cannot be unilaterally varied".

What appears to have let the Indians off the hook, at least in their own minds, is their interpretation of the underground device they exploded as a "peaceful use" of nuclear energy. This interpretation has never been shared by Canada, but it seems to have been India's all along. Canada signed the Nonproliferation Treaty but India refused on the grounds that it was "discriminatory".

Canada did win inspection provisions for the two Rapp power reactors by the International Atomic Energy Authority but there were no such provisions for the CIRRUS reactor. CIRRUS seems the most likely source of plutonium for the device. For other reasons: AECL officials say that the one Rapp reactor now running has not been operating long enough to produce sufficient plutonium for an explosive device. The Rapp reactors are of the Candu type, fuelled with natural uranium and they are not ideal for producing weapons grade material in any case.

The CIRRUS was initially fuelled by Canada but subsequent fuel was manufactured by the Indians themselves, according to Canadian officials. The Indian fuel was not subject to inspection. Thus the plutonium for the device could have come from the Indian fuel and have been separated out in India's reprocessing plant, which has been operating since 1964. In fact, press reports in India were said by a spokesman in Canada's Department of External Affairs to have quoted Indian officials as saying that this was the case.

Asked for his personal reaction to news of the explosion, J. L. Gray, President of AECL, said quite frankly "I was really quite surprised and very disappointed". Gray suggested that halting Canada's nuclear assistance at this point will have little effect on India's nuclear power programme. "It might delay them but it won't stop their programme," he said. One of the Canadian-built Rapp reactors is already running, the other is nearly finished and India is building four more of its own.

In future Canada will try to assure that there is no ambiguity about the meaning of the phrase "peaceful uses" in agreements with other countries. But it is not clear how that will be accomplished for Mr Trudeau's 1971 letter to Mrs Gandhi seemed clear enough. Mr Sharp said that Canada "made it clear in international discussions and in bilateral exchanges with India that the creation of a nuclear explosion for so-called peaceful purposes could not be considered as a peaceful purpose within the meaning of our cooperative arrangements".

India's action has also brought up the question of Canada's aid programme to that country in general. Mr Sharp said that Canada is conscious of the very large costs involved in the development of nuclear energy for peaceful purposes and appreciates the substantial resources needed for the development of explosive devices. "Canada does not intend to share the burden of relieving such costs" he said. Thus the Canadian government is not prepared to agree to any roll over of India's commercial debt to Canada which is largely related to her nuclear energy programme.

Apart from the danger of nuclear weapons proliferation, many Canadian officials have found it hard to understand the rationale of putting a high priority on an expensive nuclear device which has a questionable utility while such vital national problems as assuring an adequate food supply continue to go unresolved. Indian spokesmen said the device was needed to aid in developing new energy sources, but understood nuclear devices have not been notably successful in such uses, even in the United States.

Oil from Russia?

from our Soviet Correspondent

SPEAKING in London recently, Academician Vladimir A. Kirilin, Deputy Chairman of the Council of Ministers of the USSR and Chairman of its State Committee for Science and Technology, called for cooperation between Britain and the USSR over energy matters—both in nuclear energy and oil production.

The occasion was the third meeting of the Permanent UK/USSR Intergovernmental Commission for Cooperation in the fields of Applied Science, Technology, Trade and Economic Relations. Mr Peter Shore, Secretary of State for Trade led the United Kingdom delegation and pre-

sided; Academician Kirilin headed the Soviet delegation.

The meeting paid considerable attention to ways of implementing the recently signed (May 6, 1974) Ten Year Agreement on the Development of Economic, Scientific, Technological and Industrial Cooperation, studying, in particular, the cooperation in major technological projects on a compensation basis and the necessity for flexibility in planning individual cooperative ventures.

It was recommended that further exchanges should take place in the fields of crystal structure and macromolecules, astronomy, phase synchrotron radiation, plasma physics, hydrostatic extrusion, corrosion and tribology.

At the press conference after the meeting, Academician Kirilin said that cooperation in the field of breeder reactors "in which both countries have had notable achievements" could considerably reduce the cost of energy production.

As to oil production, he said that talks have begun with British Petroleum, to be continued in Moscow next month, to outline a possible scheme by which the United Kingdom would provide the plant and that in return the Soviet Union would deliver oil for BP "for we do not expect at he moment, the UK will deliver oil to the Soviet Union!". This, however, he stressed, is still in the planning stage, and a number of possible options for cooperation in this field lie open.

Speaking generally, Academician Kirilin stressed that the current round of talks and, indeed, the 10-year agreement could only bear their full fruit in an atmosphere of detente and cooperation, which, he averred was a fundamental tenet of Soviet foreign policy. This raised a number of questions about the rights of scientists to emigrate, and what proportion of the goods to be exchanged had originated in Labour Camps (the questioner was doubtless thinking of *The First Circle*). Academician Kirilin replied that there were no labour camps in the Soviet Union, and that because of semantic difficulties, this question could not be profitably discussed, that "almost all" scientists who wished to emigrate could do so—the exceptions being those concerned with national security, and that as for the Panovs (who as dancers could hardly fall into that category), he personally had never heard of them until he came to London, but he was sure their fate "would be dealt with fairly". At which point, in the cause detente and cooperation, Mr Shore intervened and brought the discussion back to the safer channels of mutual economic benefits and exchange.

After the conclusion of the official talks, the Soviet delegation began a programme of visits to laboratories and research establishments with which possible cooperation was envisaged. The first visit on the programme was to the fusion laboratories at Culham, where Academician Kirilin presented a paper read on his behalf by Dr John Chubb, on the present and future energy situation in the Soviet Union. His data seemed perhaps, a little on the optimistic side—fast-neutron reactors a practical possibility by 1985, and it was interesting to note that in spite of the importance which he places on cooperation in thermonuclear research as a source of cheap power in the future, he stressed the immediate emphasis in the Soviet Union on the coal industry, and recommended a rethinking of the advantages of coal to the West!

Archaeology in crisis

from a Correspondent

A BASIC reorganisation of archaeological excavation in Britain is heralded in a recent press release from the Department of the Environment. It scarcely hints, however, at the underlying problems created by the increase in rescue archaeology, and by the apparent failure of the Department of Education and Science to respond to the current archaeological crisis with the awareness shown by its sister Department.

Mr Crosland's announcement promises an increased grant of £1,063,000 for rescue excavation and post-excavation work in Great Britain during 1974–5. When compared with the grant of £440,000 for 1972–3, and £813,000 for 1973–74, this shows a continuing awareness of the widespread destruction which urban development and mechanised farming are wreaking upon what is left of Britain's past. For the evidence can be rescued only now, before it is gone for ever.

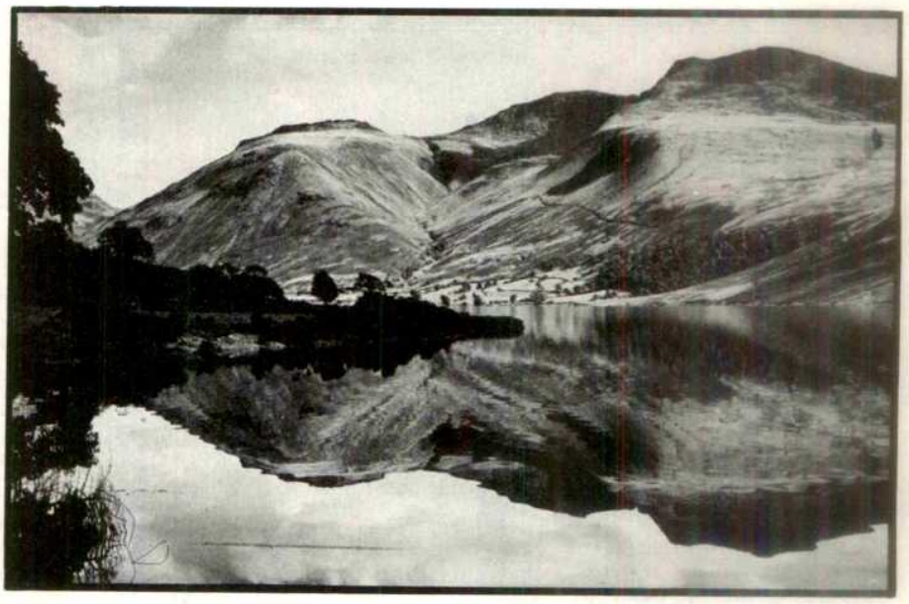
The accelerated growth of rescue archaeology in this country has created its own practical problems, however. There is a shortage of skilled archaeological fieldworkers for the senior positions, and especially of trained diggers—the equivalent, in a sense, of laboratory technicians in the natural sciences. Even so, there are now many hundreds of these diggers, working all the year round, replacing at least in part the amateur archaeologists who until a decade ago made up the entire work force on any summer dig. The emergence of what is in effect a new profession—of full-time digging archaeologists—requires some coordination in terms and conditions of employment, and trade union membership is now under active discussion (*The Times*, May 25, 1974). The formation of some sort of Association of Professional Archaeologists has now been proposed, which could propose and promote some unified career structure, serving the varied interests of archaeologists in museums, the universities, the civil service and the local authorities as well as the full-time diggers.

These logistic questions are less important, however, than the crucial one of using the annual rescue budget of £1 million to good effect. Hitherto this has been entirely the responsibility of the Ancient Monuments Inspectorate of the Department of the Environment —and its very title recalls that until a decade ago the Inspectorate's principal task was the maintenance of the ancient buildings and archaeological sites under its guardianship, and the protection from destruction of other sites listed as scheduled monuments. The explosive growth of rescue excavation, financed by the Department of the Environment, has put heavy new responsibilities upon its archaeological personnel.

The second, and ultimately more important part of the Minister's announcement takes account of this by setting up a number of advisory committees. The first is a new national advisory committee (a sub-committee of the Ancient Monuments Board, which advises the Secretary of State on the scheduling of Ancient Monuments) to advise on the priorities of archaeological excavation in England. In addition 13 advisory committees are to be set up on a regional basis to advise on local priorities for rescue excavation and archaeological survey where sites are threatened.

It remains to be seen how this structure of regional committees and a national committee will operate (and there has been immediate criticism that the regional committees are not to have direct representation on the national committee). But at least it goes some way to meet a fundamental point, which the urgency of rescue excavation and the expenditure of public money upon it both at national and local level, has sometimes served to obscure. The only purpose of rescue excavation, where the site itself is by definition doomed, is the provision of information about the past. All rescue excavation is research, aimed at providing new information to enlarge our knowledge and understanding of the post. Yet hitherto, as both the Council for British Archaeology, and Rescue, The Trust for British Archaeology have pointed out, there has been no coherent research strategy of any kind in this country. Sites have been dug simply because they were threatened with destruction. But while this is a necessary condition for the expenditure of public funds, it is certainly not a sufficient one, for even the increased funds allow for the complete excavation of only a tiny fraction of the sites threatened. In general, in-

deed, there is too much hasty digging and not enough thinking, resulting in the production of large quantities of data without any clear idea of just what prolems it is supposed to solve. Moreover the total failure of publication to keep up with the increase in excavation has recently been stressed (Addyman, *Rescue News*, **6**, 1; 1974), nor can all the publications which appear be rated as significant contributions to our knowledge of the past. These are problems which the new advisory committees must now tackle urgently if the increase in rescue excavation is to be in any way effective in counteracting the loss of evidence by development and destruction. The task now is to make rescue research more effective in terms of significant results and their rapid publication.



And it is here that the Department of Education and Science has so far failed for, unlike the Department of the Environment, it actually has a formal public commitment to scientific research. Now, archaeological excavation under the often hasty conditions implied in rescue work, does not offer the ideal laboratory for the development of new techniques and the investigation of entirely new approaches to the past which are essential for real progress. Yet archaeological research is considered as outside the field of interest of each of the three research councils (SRC, SSRC and NERC) which might be expected to support it, to the extent that the only way an archaeological research project can find support from them is to masquerade as something else and lodge itself in a department of physics or geology. The British Academy, to be sure, makes a number of small grants, but these are distributed over the whole field of the humanities. Some time ago the British Academy and the Royal Society held joint discussions on this curious state of affairs. It is believed that they resolved jointly to approach the Department of Education and Science with a view to the institution of some body, analogous to the SRC or to NERC, by which scientific research in archaeology could be supported. But so far nothing more has been heard. So we have the paradox that rescue excavation is supported by the government on an increased scale, reflecting real awareness of the archaeological crisis, while the further scientific research which should exploit this great opportunity by analysing existing data and by developing new techniques, is simply not taking place. Archaeological research in Britain is thus in a state of considerable confusion. Mr Crosland's advisory committees will have to work long and think clearly if the funds for rescue excavation are to yield commensurate scientific and historical rewards.

The future of National Parks

Peter J. Smith

ACCORDING to the late John Dower, a National Park in the British context was to be "an extensive area of beautiful and relatively wild country in which . . . . (a) the characteristic landscape beauty is strictly preserved, (b) access and facilities for public open-air enjoyment are amply provided, (c) wildlife and buildings and places of architectural and historic interest are suitably protected, while (d) established farming use is effectively maintained". The precise wording of the National Parks and Access to the Countryside Act 1949, under which the ten National Parks of England and Wales were later created, was slightly different that they were to be designated areas in which an attempt would be made by careful control to avoid radical change in either natural or man-made characteristics whilst encouraging greater recreational use.

Twenty-five years later the result, now examined by a committee under Lord Sandford (*Report of the National Park Policies Review Committee*, HMSO, London, 1974), can be seen to be mixed. There is no doubt that the National Parks have managed to maintain some distinction and are generally held in high public regard, but at the same time they have been eroded to a much greater extent than their creators envisaged or would have desired. Part of the conflict between the ideal and the reality has arisen because, rightly or wrongly, the 1949 Act made no attempt to change the ownership of the land within the designated areas, and so total responsibility for each park has never been in the hands of a single administration. This lack of complete control by park authorities has been particularly unfortunate where it relates to the use of land previously established for farming.

The Scafells across Wastwater : inviolate?

As Sandford points out, the scenic quality of the man-made part of the environment in National Parks is due primarily to the grazing of sheep and cattle, which maintains the characteristic open landscapes. But large scale afforestation of open land with alien conifers has taken place as a result of national economic decisions—a development which park authorities have been largely powerless to prevent, and heather moorland and other rough grazing have been converted to more productive pasture altering the open character of the country and impeding access. The political difficulty is that in the last resort the park authorities have little power over the activities of private landlords. Sandford therefore recommends that where mutual agreement on land use proves impossible, the authorities should have the power of compulsory purchase, and that afforestation in particular should be subject to planning controls.

As for development, parks have generally been able to avoid excessive residential and small-scale commercial development but there has been what many people take to be a deplorable amount of large-scale development, generally under pressure from central government and supposedly "in the national interest". Sandford's view is that because the National Parks account for 9% (over 3.3 million acres) of the area of England and Wales, and contain important mineral and water resources, it would be unrealistic to hold them inviolate against such development. At the same time, the

report acknowledges that "in the past amenity values appear to have been set aside too easily", and suggests that in future there should be a strong presumption against development which conflicts with park purposes.

Some of the parks' more obvious difficulties have arisen from the inherent conflict between preservation, on the one hand, and public enjoyment of the preserved facilities, on the other; the ever-increasing number of visitors has begun to threaten the very characteristics which attract the visitors in the first place. Road alterations have been carried out with no overall scheme in mind and in ways more appropriate to the urban than the rural environment; cars, coaches and caravans have been allowed to penetrate 'sensitive' areas; and roadside walls and verges have suffered from over-heavy vehicles.

The general problem here as Sandford sees it is that both park authorities and the government have been slow to react to changing circumstances; they have failed to come to terms with the fact that, although the walkers and climbers in the forefront of thinking during the 1940s are now more numerous than ever, the drivers have multiplied at an even higher rate. What, specifically, should be done? The Sandford recipe includes the routing of new trunk roads around the National Parks, the abandonment of any attempt to maintain uncongested traffic flow within the parks by means of new road development, refusal to permit alterations in existing road width or alignment, encouragement of peripheral parking linked to public transport inside the parks, and the resiting and screening of prominent caravan sites. Of course, it is one thing to identify sensible solutions, but quite another to carry them out—and the Sandford committee goes little into detailed implementation. On the other hand, there can be no doubt that the basic principle is sound and worth restating—that where the preservation and enhancement of beauty conflict acutely with the promotion of public enjoyment, the former must prevail.

Finally, the report suggests that there should be designated "national heritage areas" in which "the conservation of environmental qualities would be the supreme objective . . . . taking precedence over all others". There would be no settlement larger than a hamlet, no industrial development, no quarrying or mining, no reservoirs or defence works, no main roads or railways, no facilities for visitors, and visitor access would be limited to foot, bicycle and horse. This is the one genuinely radical suggestion in the whole report, although it is actually a minority proposal from four members of the committee. It deserves the widest debate, for this may be the last available opportunity for conserving "areas of the highest environmental quality".

Chilean symposium

SIR,—We are scientists who firmly hold political opinions which differ from one to another. We are not concerned to try and understand these differences. We are, however, convinced that every scientist (like every nonscientist, indeed) has the right to hold what ideas he likes and to maintain them within his own country in the manner which he deems best.

We are similariy convinced that all political matters should be excluded from international scientific associations. Officialdom, no more than the organisers of, or the participants in international meetings, should neither impose nor allow any mixing of science and politics.

This is why we object to the following phrase "the re-establishment of social peace and internal order guarantees and secures to carry out this scientific event" in the invitation emanating from the Chilean section of the International Association of Volcanology and Chemistry of the Earth's Interior to attend a symposium in Santiago.

We cannot accept that a regime which has covered its large and unhappy country with blood, and which still continues to permit torture and political assassinations, should be permitted to include such a phrase in its circular of invitation to foreign scientists.

Needless to say, we do not propose to participate in this symposium and are of the opinion that a similar attitude should be adopted by any volcanologist sensible of the terrible Chilean tragedy, since his very presence there might tacitly imply tolerance from the human point of view.

Yours faithfully,

Spilt milk

SIR, — John Hall rightly adduces several arguments against the change from breast feeding to bottle feeding which is apparent in less developed countries. But his description of the character of the "Baby Killer", bottle feeding, is incomplete as it does not mention an effect of bottle feeding that will probably kill even more babies than the associated infections, malnutrition and poverty do. Lactation postpones postpartum ovulation and therefore contributes to birth spacing. It has been shown that prolonged lactation is indeed an important factor in controlling population growth. Populations in less developed countries that are changing from breast feeding to bottle feeding are likely to be insufficiently familiar with other means of family planning to compensate for this growth mechanism. I know of a case where all the female patients in a rural East African hospital were given a bra as a Christmas present, though family planning programmes in that area had not yet yielded any obvious result and the women concerned had hardly ever shown interest in bras. Whether due to well-intentioned grafting of our breast-centred culture into less developed cultures or due to deliberate promotion of dairy and bra industries, such behaviour is likely to add to baby killing population pressures. We should be aware of such incipient trends disturbing the balance between mortality and birth rates in less developed countries in addition to those already caused by Western medicine and technology.

Yours faithfully,

J. WIND

Gene expression in development

DIFFERENTIAL gene transcription is often put forward as the major source of control for protein synthesis during differentiation and development. But there are other possibilities such as nuclear processing and selection of messenger RNA for transport as well as various forms of translational control. It is clear that gene expression has a quantitative and a qualitative aspect since highly specialised cells such as reticulocytes, lymphocytes, silk gland and lens cells all produce a large amount of a few polypeptide chains and a small amount of a much larger number of proteins. Greater rates of transcription from genes appropriate to the end cell line may account for the quantitative differences in protein synthesis observed in these cells, although other possibilities such as differential mRNA stability, for which there is some evidence (Kafatos, *Fifth Karolinska Symposium*, 319; 1972) are not rigorously excluded.

Presumably gene expression also has a qualitative aspect but examples are harder to find and interpret since the answers obtained depend on the level of discrimination set by the techniques used in the analysis. Nucleic acid hybridisation procedures have recently provided evidence in a variety of systems for qualitative differences between RNAs extracted from different adult organs of the mouse (Brown and Church, *Devl Biol.*, **29,** 73; 1972); Grouse, Chilton and McCarthy, *Biochemistry*, **11,** 798; 1972) and different developmental stages of the slime mould *Dictyostelium* (Firtel, *J. molec. Biol.*, **66,** 363; 1972). These workers have used purified labelled unique DNA sequences in nucleic acid hybridisation reactions with RNA in excess to investigate the proportion of unique DNA sequences represented by RNA transcripts in any given RNA preparation. Either total cell or total nuclear RNA preparations have been used to drive the hybridisation reactions. To compare two RNA preparations they are hybridised separately and together under identical conditions and the amount of labelled unique DNA found in RNA/DNA hybrids can then be determined. From the results it is possible to compute the sequences common to both and also those present in one but not the other. For instance, in *Dictyostelium*, Firtel has shown that about 20% of the genome is represented in RNA at all stages of development and about 37% consists of sequences expressed at particular developmental stages. These studies provide evidence for qualitative changes in gene transcription during developmental and differentiation, but do not throw light on the question of qualitative differences between nuclear and cytoplasmic unique gene transcripts.

Two recent articles (Smith, Hough, Chamberlin and Davidson, *J. molec. Biol.*, **85,** 103; 1974; Galau, Britten and Davidson, *Cell*, **2,** 41; 1974) suggest in a developmental situation that the total number of diverse unique DNA sequence transcripts in nuclear RNA is ten times greater than in mRNA from polysomes. Using sea urchin embryos at the gastrula stage of development Smith *et al.* isolated heterogeneous nuclear RNA (hnRNA) labelled by a 10 min pulse of ^{3}H-uridine. The hnRNA was fractionated in non-denaturing sucrose gradients to give three fractions sedimenting less than 23S, between 23 and 40S and greater than 40S. The greater than 40S fraction was used for hybridisation experiments with unlabelled sheared total DNA in excess under various conditions.

First the amount of hnRNA hybridising to DNA by C_0t 40 was determined at two DNA/RNA ratios. These conditions represent an assay for repetitive sequence transcripts since by C_0t 40 75% of repetitive DNA sequences but less than 5% of single copy DNA should have reannealed. About 25% of total ^{3}H-labelled hnRNA is recovered in hybrids separated from non-hybridised RNA on urea hydroxyapatite columns. Treatment with ribonuclease before recovery of hybrids reduces this value to 5–8% of total ^{3}H-hnRNA, suggesting that one-fifth to one-third of the hnRNA hybridised by C_0t 40 is in DNA/RNA duplex and the rest is in unhybridised RNA tails which are removable by ribonuclease treatment. RNA size was determined before (3,000 nucleotides) and after (1,100 nucleotides) hybridisation suggesting that during hybridisation and subsequent isolation of hybrids the RNA is cut on average once or twice per molecule. Assuming the cuts are random and that there is no more than one repetitive element per bound fragment, then about 70% of the hnRNA molecules entering the reaction should contain one such sequence. If on the other hand some bound fragments were composed wholly of repetitive sequences and others contained smaller than average sized repetitive sequences this value will be lower but was calculated to be not less than 50%. Other interpretations, such as 75% of molecules composed of non-repetitive sequences and 25% composed of intermingled repetitive and non-repetitive elements, do not, however, seem to have been excluded.

Another point of interest is that the average size of repetitive and non-repetitive sequences in the hnRNA C_0t 40 hybrids can be computed from the average length of hybridised molecules (1,100 nucleotides) and the proportion of hybrid which is resistant to ribonuclease (20–35%). Repetitive sequences in sea urchin gastrula hnRNA are therefore about 300 nucleotides long, a figure which is in good agreement with the average length of interspersed repetitive sequences found in sea urchin (Graham *et al.*, *Cell*, **1,** 127; 1974) and *Xenopus* DNA (Davidson *et al.*, *J. molec. Biol.*, **77,** 1; 1973).

Smith *et al.* next investigated the hybridisation of hnRNA to non-repetitive DNA sequences by allowing the hybridisation reaction to proceed beyond C_0t 40 and up to C_0t 4,000 at which point about 47% of the ^{3}H-labelled hnRNA is in hybrid; this value can be increased to 65–70% at very high DNA to RNA ratios. It is clear from the shape of the C_0t curve that a large proportion of hnRNA molecules contain sequences transcribed from non-repetitive DNA. Although the detailed interpretation of these results suffers from some uncertainties—mainly to do with possible variation in specific activity of the reacting species—the suggestion is that a few unique sequences are present in hnRNA in much greater amounts than others, since only at very high DNA/RNA ratios are there enough sites provided for most of the RNA to hybridise. Most unique sequences in hnRNA are present in relatively few copies since there is essentially no increase in hybridisation at C_0t 4,000 from a DNA:RNA ratio of 30 up to 15,000. This means that enough single copy DNA sequence is present at the lower ratio to hybridise the bulk of the sequence complexity in hnRNA. Although it is not possible directly to calculate non-repetitive sequence

complexity from these results (RNA-driven reactions are required for this), a rough minimum estimate of 10% of the unique sequence of the total genome is obtained. Preliminary results using RNA-driven hybridisation reactions indicate a value two or three times greater.

In order to compare the genetic information in hnRNA with that in polysome-bound mRNA it is necessary to estimate the proportion of unique DNA sequence complexity present in cytoplasmic mRNA. Galau *et al.* have done this for sea urchin gastrulae using RNA-driven hybridisation reactions with ^{3}H-labelled purified non-repetitive DNA as the probe. First they isolated polysome-bound RNA by procedures previously shown to extract most of the cytoplasmic mRNA essentially free of hnRNA although containing substantial amounts of ribosomal RNA (Goldberg, Galau, Britten and Davidson, *Proc. natn. Acad. Sci. U.S.A.*, **70,** 3516; 1973). This was hybridised with ^{3}H-labelled non-repetitive DNA in 3–40 fold excess RNA for various lengths of time to give RNA C_0ts up to 60,000. Since DNA renaturation is not prevented subsequent analysis distinguished between DNA/DNA and DNA/RNA duplex. It was found with four different RNA preparations that a maximum of 1% of the total ^{3}H-DNA enters DNA/RNA hybrids. Proof that termination of the hybridisation reaction is due to exhaustion of DNA sequences complementary to mRNA was provided by reisolating unreacted ^{3}H-DNA and rehybridising it to a further sample of RNA. Only 0.02% formed new hybrid although when annealed with excess cold DNA most of it would still enter DNA/DNA duplex. The non-repetitive DNA probe contained as contamination a small amount of repetitive sequence and proof that the DNA in the RNA/DNA hybrid is non-repetitive DNA was given by reisolating the DNA from the hybrids and reacting it with an excess of sheared total DNA, when it renatured with the kinetics expected of unique sequence DNA. From these data in a calculation which allows for asymmetric transcription and the measured proportion of DNA unavailable for hybridisation, Galau, Britten and Davidson conclude that 2.7% of the total single copy DNA sequence is represented by RNA transcripts in gastrula polysomes. Assuming a number-average length for mRNA of 1,200 nucleotides, this means that about 14,000 different mRNAs are present at this stage of development. It was calculated that only about 8% of the mRNA (called the complex class) drives the hybridisation reaction and contains 90–95% of the total sequence complexity. The rest (called the prevalent class) contains only 5–10% of the sequence complexity since no early low RNA C_0t transition was seen during the course of the reaction. From these figures, together with estimates for the total amount of mRNA in gastrula polysomes, the average number of complex class mRNA molecules per gene at any one time was calculated at 340; for the prevalent class of mRNA this figure must be two orders of magnitude greater.

It is clear from the results of these two papers that the proportion of the unique DNA transcribed into hnRNA is at least four times and maybe ten times greater than the proportion in active polysomes of sea urchin gastrulae. There is considerable debate at present over the possible role of hnRNA as a nuclear precursor to mRNA. If it is, these results suggest that 75–90% of diverse unique sequence transcripts present in nuclear RNA do not reach the cytoplasm, that is processing restricts qualitatively with respect to sequence the mRNA appearing in the cytoplasm.

This result is particularly interesting as it provides evidence for control of gene expression at a level beyond transcription. But before this interpretation can be accepted it is important to ascertain what proportion of the unique DNA sequences code for protein, and also that the unique sequence transcripts present in hnRNA but absent from the cytoplasm are representative of sequences which do code for proteins and do not have some other function.

PETER J. FORD

Einstein in crisis?

IN spite of the great aesthetic and philosophical appeal of Einstein's general theory of relativity, it is still, after 50 years of widespread acceptance, one of the least well-founded theories in physics as far as experimental confirmation is concerned. Of the three classic tests of the theory, the most impressive concerns the motion of the planet Mercury. In the nineteenth century it was known to Leverrier that the perihelian of Mercury's orbit precessed around the Sun at a calculated rate of 43 arc seconds a century. Such a deviation from a perfect elliptical orbit, although very small, was none the less a significant enough departure from Newton's theory of gravitation to lead to the search for an undiscovered planet (which even had a name—Vulcan) which supposedly lay within the orbit of Mercury, and was responsible for perturbing its motion.

Vulcan was not found, and in 1915 Einstein published his theory of relativity which beautifully accounted for the discrepancy in Mercury's motion. This success must be regarded as the backbone of observational support for the general theory of relativity, so that any questioning of the result must be regarded with the gravest concern. To question the result is just what Dicke of Princeton University has been doing for some years, by directing his attention to the shape of the Sun. As a result of a long series of observations, Dicke claims to have detected a solar oblateness (a difference between the polar and equatorial radii) of $(4.51 \pm 0.34) \times 10^{-3}$%. The details of the observations, together with a tentative theory of the solar interior, are published in a recent issue of *Science* (**184,** 419–429; 1974).

Dicke interprets the solar oblateness in terms of an uneven distribution of mass in the Sun's interior, leading to a small but significant quadrupole moment of $(2.47 \pm 0.23) \times 10^{-5}$. The presence of such a quadrupole moment would have a profound effect on the motion of Mercury; it would in fact reduce the perihelian precession by three arc seconds a century—a discrepancy of 7% from the relativity result.

Under these circumstances there are always a number of alternative theories of gravity waiting in the wings, and it is no coincidence that one of the more serious contenders also comes from Dicke. Known as a scalar–tensor theory, it is based on the idea that as well as the usual gravitational field which surrounds a massive object, there is an additional (scalar) field which adds a fraction, for example, s, to a body's weight. The value of s is not determined by the theory, but is generally held to be about 15–20%. Calculations using the scalar–tensor theory show that Mercury's perihelian would still precess, but at a somewhat reduced rate. If s is about 15%, the reduction is around four seconds of arc a century. Not surprisingly, Dicke believes that the scalar–tensor theory is in better agreement with the observations than is Einstein's theory, provided that the solar oblateness interpretation is accepted as well.

It is unlikely that a large oblateness would be believed by astronomers unless there were a fairly good theory of stellar structure to go with it, and Dicke outlines such a theory in his *Science* article. One likely explanation for a quadrupole moment is the possibility that the interior of the Sun might be rotating faster than the surface. To obtain an effect of the right magnitude, it is necessary to have a solar core rotating at 20 times the surface value.

It is thus necessary to account for the relatively slow rotation of the surface layers. Interestingly, there is a ready made explanation available, provided by the 'solar wind'. This consists of streams of high velocity charged particles continually shooting out from the surface of the Sun. Such particles would couple strongly to the Sun itself through any magnetic field present, and would have the effect of 'braking' the relatively tenuous outer surface of the Sun as the field twists up because of rotation.

Needless to say, the presence in the solar interior of a high differential rate of rotation raises deep problems concerning stability. Nevertheless, observations of the rotation rates of other stars slightly more massive than the Sun indicate that young stars do indeed rotate about 20 times faster than the surface of the Sun, but that this rate falls off progressively as the star ages, presumably as a result of magnetic braking. The crucial question though, is whether the interiors of the older stars (such as the Sun) are still spinning at a very high rate. Extraordinary evidence that this might be so is provided from an unlikely source.

In order that the solar surface continues to rotate under the breaking action of the solar wind, there must be a coupling between the rapidly spinning core and the surface, to provide a mechanism for the transfer of angular momentum. One such mechanism, involving turbulent diffusion of the solar fluid, carries angular momentum upwards, but also carries lithium downwards. Lithium is produced in certain quantities in all stars, but in the Sun there is apparently a depletion by a factor of 200 from the expected abundance near the surface. Dicke advances this as evidence of a rapidly rotating core.

These provocative ideas of Dicke have caused a great deal of controversy in recent years. Nevertheless, at this time, he feels that criticisms have been well met, and that Einstein's theory faces a very real crisis. Naturally, the case cannot be decided on the basis of solar oblateness arguments alone. The complexities of stellar structure, and our ignorance concerning the condition of the Sun below its visible surface layers, preclude such sweeping conclusions. One other possibility of discriminating between the scalar–tensor theory and general relativity concerns the value of the Newtonian gravitational constant G, which in the former theory is actually a time-dependent quantity. The extremely slow variation of G predicted by Dicke may soon be accessible to observation using radar-ranging techniques to measure the motions of the nearby planets. The importance of the issue at stake should lead to observations like these being vigourously pursued in the next few years.

P. C. W. DAVIES

Does the geomagnetic field affect climate?

ALTHOUGH the suggestion that there may be a relationship between climatic changes and variations in the Earth's magnetic field was first made more than 20 years ago, convincing correlations between the two have been discovered only much more recently. The surprise is not that it took so long but that it ever happened at all. For what possible connection could there be between phenomena so obviously disparate? Yet the correlations exist; and although a direct causal relationship may be genuinely doubted, the fact that climate and geomagnetic field are linked at all raises the need to identify the intermediate factors by which the correlations come about.

Apparently for historical reasons, some workers have drawn significance from the fact that both climate and magnetism seem to be related to fluctuations in atmospheric radiocarbon activity. De Vries (*Proc. K. ned. Akad. Wet.*, **B61**, 94; 1958) seems to have been the first to propose a correlation between radiocarbon activity and climatic changes, in which he was followed ten years later by Damon (*Met. Monogr.*, **8**, 151; 1968); but by Damon's time Elsasser *et al.* (*Nature*, **178**, 1226; 1956) had already pointed out that radiocarbon activity was likely to be influenced by changes in the magnetic field. The argument here is that the cosmic radiation entering the atmosphere to generate the radiocarbon will be reduced if the strength of the geomagnetic field is increased, for the field has a shielding effect—and this phenomenon has received support from many subsequent workers. So variations in the intensity of the Earth's magnetic field fluctuations in atmospheric radiocarbon activity and climatic changes are apparently correlated for the past 7,000 yr, and there is a clearly understood relationship between the magnetic field and radiocarbon activity. Unfortunately, however, all this does nothing to explain just how and why climate comes to be involved.

More recently, important, albeit phenomenological, light has been thrown on the climate connection by the work of Wollin and his colleagues at the Lamont-Doherty Geological Observatory. Wollin *et al.* (*Earth planet. Sci. Lett.*, **12**, 175; 1971), for example, examined deep sea sedimentary cores for the past 470,000 yr and found that changes in the intensity of magnetisation and the palaeomagnetic inclination of the sediments could be correlated with the climatic changes in the same sediments as represented by variations in, for example, the abundance of *Globorotalia menardii* and the coiling direction of *G. truncatulinoides*. As a result, they tentatively concluded that a "cause and effect relationship links changes of the Earth's magnetic field and climate" (for example, that higher magnetic intensity produces, or is produced by, colder climate). They also suggested that "it is possible that magnetism may modulate climate to some degree by the shielding effect against solar corpuscular radiation provided by the Earth's magnetic field"—thus invoking a clear, if perhaps forced, analogy with the phenomenon known to affect cosmic rays. Later, Wollin *et al.* (*Nature*, **232**, 549; 1971) used other deep sea cores to extend the correlation between magnetisation variations and climatic changes back to 1.2 Myr.

The best way of summarising the work of Wollin and his colleagues on deep sea sediments would probably be to say that the correlations themselves are convincing whereas the explanation is not, which is why Amerigian (*Earth planet. Sci. Lett.*, **21**, 321; 1974) has sought to produce something "simple and less astonishing". Amerigian's basic point is that at least equally feasible causes of the observed correlations may be invoked, based on seafloor dynamic processes already known and known to be climatically variable. For example, one of the principal factors affecting the intensity of magnetisation of sediments is the intensity of magnetisation of the particles which settle to form the sediments in the first place, and this in turn depends on composition. Most of the cores examined by Wollin *et al.* were high in organic calcium carbonate and, as Amerigian shows in a scatter plot, the greater the proportion of essentially non-magnetic calcium carbonate present in a sediment the lower (statistically) is the sediment's intensity of magnetisation. In other words, calcium carbonate production, which is climatically controlled, can affect intensity of magnetisation in a way which is completely unrelated to the strength of the geomagnetic field. Under such circumstances it would clearly be unwise to suppose that a correlation between intensity of magnetisation and (other) climatic indicators necessarily implies one between geomagnetic field intensity and climate.

The second important factor influencing the intensity of magnetisation of sediments is the efficiency of the process by which the settling particles are aligned into the prevailing magnetic field direction, and this in turn is related not only to the strength of the field in which the deposition takes place but also to the grain size distribution of the magnetic material involved. Materials with different grain size distributions may settle out into the ambient field direction with different efficiencies (that is, the proportion of material attaining a magnetically controlled orientation will vary) depending on the current velocity. Thus if the bottom current velocity is related to climate, the intensity of magnetisation of the sediment will be partly related to climate. Again, then, it does not necessarily follow that a

correlation between intensity of magnetisation and climatic indicators means that the latter correlate with geomagnetic field strength.

Amerigian then goes on to show that the reported correlations between palaeomagnetic inclination and climatic indicators can result from variable inclination errors introduced by bottom-current velocity changes which are also climatically controlled. He does recognise, however, that his various mechanisms are only valid if the magnetisations of sediments are depositional rather than post-depositional, for climatically controlled depositional processes can obviously only be relevant to the observed correlations as long as sediment magnetisations arise at the time the sediment is formed. There are known to be several ways in which post-depositional magnetisations can be, and probably are, produced, although it is by no means clear that such processes are universal. In any case, Amerigian's aim seems to be less to push particular explanations or combinations of explanations, for the observed correlations than simply to demonstrate that the correlations need not be direct.

Where Amerigian may be on less certain ground is in his treatment of correlations between directly observed geomagnetic field changes and climatic variations. Since their work on sedimentary cores, for example, Wollin *et al.* (*Nature*, **242**, 34; 1973) have reported just such correlations, but Amerigian dismisses them because of what he takes to be "unsatisfactory" data selection. Whether or not he is justified in this particular instance, the fact is that other workers are also finding relationships between magnetism and climate. It is by no means clear that these will be so easily refuted.

PETER J. SMITH

Lymphocytes at war

IT is a precept of many immunologists that the primary role of the vertebrate immune response is defensive, enabling the responding organism to resist attack by such foreign agencies as bacteria and viruses. Although there are objections to this notion—for example that invertebrates do not have such specific immune responses and yet they seem to defend themselves well—attack and defence have become so firmly rooted in the thinking of immunologists that many of their present-day analytical methods could be described as war games. One of the games with the most immediate impact is that which is fought *in vitro* between two genetically and thus antigenically distinct cell populations. It is supposed that the outcome of this battle in some way reflects the manner in which foreign mammalian cells are dealt with in the living animal after tissue or organ transplantation. There is also the idea that tumours are antigenically distinctive and thus the various kinds of stimulation which can be shown *in vitro* are a manifestation of an anti-tumour surveillance mechanism. Like many war games the moves of those played by immunologists are complex and irritatingly abstruse to the uninitiated. Three recent communications in *Nature* illustrate the genre.

Lafferty and his colleagues Misko and Cooley (*Nature*, **249**, 275–276; 1974) lay down the basic rule of their game in their first sentence. In translation it says that the response to a particular set of transplantation antigens *in vitro* is sometimes enhanced if there is a second and different set of antigens available to respond: two adversaries are better than one. Lafferty *et al.* cultured the cells from the lymph nodes of C57BL/6J mice with γ-irradiated BALB/c spleen cells. This is said to be a one-way mixed lymphocyte reaction in which the outcome is simplified by inactivating the capacity of one of cell populations to respond but leaving its stimulatory property apparently intact. The severity of the reaction can be measured either by incorporation of tritiated thymidine into the cultures at an appropriate time or by subculture of the responder cells onto a ^{51}Cr-labelled tumour cell population which has some of the same surface antigens as the BALB/c stimulator cells (H-2^d).

Lafferty *et al.* go on to show that although γ-irradiated cells are adequate stimulators, ultraviolet-irradiated cells are not. It seems that ultraviolet-irradiated cells still have the relevant antigens as they are effective absorbers of the appropriate anti-H-2 antisera. If, however, to cultures containing responder C57BL/6J lymph node cells (H-2) and (poor) stimulator ultraviolet-irradiated BALB/c spleen cells (H-2^k) is added a γ-irradiated CBA spleen cell population (H-2^k), then the C57BL cells respond vigorously and generate anti-H-2^d cytotoxic cells. Lafferty and his colleagues think that their experiments raise the possibility that "the antigenic differences between donor and host may not constitute a major barrier to all transplantation" but that if the graft contains more effectively antigenic donor lymphocytes then a more vigorous response against the antigens of the major portion of the graft will ensue.

Dennert's experiments (*Nature*, **249**, 358–360; 1974) are like those of Lafferty *et al.* in that the DBA/2J mastocytoma (H-2^d) is again a target cell for attacking lymphocytes. Dennert injected the tumour into C57BL/6J mice and then assayed for cytotoxic cells in their spleens 9 days later. He found that if he used fresh tumour cells to immunise, then cytotoxicity developed but if he used cells fixed with glutaraldehyde or formaldehyde little cytotoxicity was discovered. Dennert then went on to estimate the immunological capacity of the spleens of the variously immunised C57BL mice for their 'helper' capacity by incubating them *in vitro* with trinitrophenyl (TNP)-coupled tumour cells and subsequently measuring the anti-TNP response by a plaque assay. If the spleen cells are immune anti the tumour cells then, because the tumour cells are acting as the carrier for the TNP hapten in the culture, an anti-hapten response should follow. Paradoxically the spleen from mice immunised with fresh tumour cells, which had in the other tests shown such a vigorous cytotoxic response, had little helper activity whereas those from mice immunised with fixed cells had helper activity but little cytotoxicity.

Dennert goes on to show that spleen cells with high cytotoxic capacity are also able to suppress the expression of helper function. These experiments serve to exemplify the intricacy of contemporary cellular immunology and Dennert feels that they suggest strongly that cytotoxic effector cells and helper cells are different 'subsets' of T (thymus-derived) cells in contradiction to the earlier suggestion of Kreth and Williamson (*Nature*, **234**, 454; 1971) that they were the same cells. Categorisation of heterogeneity of T cells is presently popular but it will remain to be seen whether the various putative classes are related to some basic diversity or represent alternative physiological conditions of initially the same cell populations. Thus Dennert's article raises the larger question of whether lymphocytes are heterogeneous before antigenic stimulation or even as a result of it.

The third of the trilogy by Plata and Levy (*Nature*, **249**, 271–274; 1974) draws attention to the fact that although all the effector cells in chromium release assays of cell-mediated cytotoxicity against murine sarcoma virus, induced tumours in C57BL/6 mice seem to be T cells, both T and non-T cells can be detected in the microcytotoxicity assay (Takasugi and Klein, *Transplantation*, **9**, 219; 1970). Furthermore, it proved possible to show that the capacity of T cells to kill as detected by chromium release was not blocked by serum from tumour-bearing animals whereas in the microcytotoxicity assay blocking occurred. Like Dennert, Plata and Levy wish to conclude that they are dealing with two populations of T cells distinguished by their functional capacities *in vitro*.

A. J. S. DAVIES

Pioneering Jupiter meeting at RAS

by John Gribbin

On Friday May 24 the Royal Astronomical Society broke new ground with their first meeting devoted entirely to discussion of the planet Jupiter. The stimulus to hold such a meeting at present came, of course, from the historic data gathered by Pioneer 10 a few months ago, and which are now being analysed. The process of analysis and interpretation is a long one, and although some of the speakers at the meeting are, it seems, regular acquaintances from similar meetings held at various institutions every few weeks, they have yet to hear each other covering entirely familiar ground. So what emerged from the recent RAS meeting was not in any sense a definitive statement about the nature of Jupiter—rather, a progress report of the state of the art, which raises one or two extremely puzzling questions.

The meeting began with a resume from K. Runcorn (University of Newcastle upon Tyne) of the pre-Pioneer picture of Jupiter and its radioactivity. It is now some 52 years since Jeffreys produced the first model of Jupiter, Runcorn recalled, and 37 years since advances in quantum mechanics showed that metallic hydrogen can be formed at pressures comparable to those found in the interior of that giant planet. For some two decades the presence of radio emission from Jupiter has been known—indeed it is the brightest object in the radio sky—and this ties in well with the idea of a fluid metallic core in which dynamo processes operate.

No discussion of Jupiter is complete without mention of the Great Red Spot, which rotates with a period close to 9 h 55 min 40 s, some 10 s more than the rotation period of radio features. This can be explained, broadly speaking, by Hide's model which Runcorn called "the most physically satisfying explanation of the Great Red Spot". In this model, the spot is seen as the visible part of a Taylor column produced by an irregularity (mountain or crater) in the underlying solid surface. Then, the spot period represents the rotation period of the solid mantle, and the radio period the period of the weakly coupled core.

If that is the case, it is to be expected that slight variations in the two periods—a few milliseconds or so—could be correlated in much the same way that variations in the rotation of the Earth's magnetosphere can be correlated with changes in the length of day. Tantalisingly, the available radio observations can neither confirm nor deny this hypothesis, although to my eye the curves presented by Runcorn seem to fit this proposal better than the alternative hypothesis, that the radio period is strictly constant. One thing the Earth-bound radio observations do imply is that the Jovian magnetic field is, if dipolar, inclined at about 11° to the rotation axis—and this provides a neat tie in with the Pioneer 10 data.

E. J. Smith (Jet Propulsion Laboratory, CalTech) described the Pioneer observations of the Jovian magnetic field. The data are not sufficient to define a unique model, but the simplest model which fits them is of a dipolar field, inclined at 11° and offset from the planet's centre, with a strength of 4 gauss at the equator. Closest approach of the vehicle to Jupiter was 2.8 Jovian radii, and the field showed a steady cube law dependance on distance for most of the trajectory, as expected for a dipolar field. The offset of the dipole from the centre of Jupiter seems to be about one tenth of the planet's radius (R_J), much more than the equivalent offset of the Earth's field.

The magnetosphere beyond some 20 R_J is strongly deformed from the dipolar form which is characteristically closer to the planet, and seems to contain a thin current sheet. This has an important effect on the distribution of energetic particles around Jupiter, as J. Simpson (Enrico Fermi Laboratory, University of Chicago) and R. W. Fillius (University of California, San Diego) reported.

Much of the data concerning the particle distributions and the sweeping up effect of some of the Jovian satellites is already familiar from published work, and the latest developments add little to the earlier analyses. But two intriguing features remain to be explained. First, the distribution of both protons and non-relativistic electrons peaks slightly further out from Jupiter than the Pioneer 10 periapsis. Extrapolation of the measurements suggests that there is a 'particle hole' close to the planet, and this can hardly be attributed to the influence of Amalthea since high energy (35 MeV) electrons are not affected. Pioneer 11 is now targeted to fly through this hole, so its reality should soon be confirmed. If the distribution of protons does, however, peak again close in to Jupiter then Pioneer 11 is unlikely to survive.

But the most intriguing discovery mentioned at the RAS meeting concerns the bursts of relativistic electrons apparently ejected by Jupiter. These bursts were first detected by Pioneer 10 half a year before encounter, and got bigger as the spacecraft approached the planet. Clearly they are not solar particles, since they come from the wrong direction; the idea that they might represent interstellar particles leaking in to the Solar System from outside held some appeal at one time, but now it seems clear that they do originate from Jupiter.

The crucial evidence is that once Pioneer 10 had made its dive through the Jovian magnetosphere it was possible to extrapolate back from observations of the roughly 10 h periodic variations produced by the rotation of the planet. This extrapolation showed that all the bursts seen on the way to Jupiter showed structure on a timescale of 10 h exactly in phase with the variations inside the Jovian magnetosphere. Clearly, unless Pioneer 10 had travelled in a trajectory specially favoured for particle ejection (which seems most unlikely), Jupiter must be radiating waves of particles outwards over a wide range of latitudes. This is very disturbing for established theories which suggest that particles should be nicely contained in the equatorial plane, and shows how much remains to be discovered about Jupiter. At the same time, this source of non-solar particles provides an invaluable new tool for investigating propagation of particles in interplanetary space. With Pioneer 11 still to make its (perhaps suicidal) close dive past Jupiter, it looks as if this will not be the last RAS meeting devoted exclusively to the giant of the Solar System.

East African grasses

The second part of the Graminae section of the *Flora of Tropical East Africa* (edit. by Clayton, Phillips and Renvoize; Crown Agents of Oversea Governments and Administrations, London, April 1974, £2.75) contains this drawing of *Odyssea paucinervis* which is found south of the Congo River on saline soils between 1,800 and 1,900 m.

Ambiguous gravity

from Peter J. Smith
Geomagnetism Correspondent

THE chief difficulty in gravity interpretation is that gravity anomalities by themselves can never be used to determine subsurface structure uniquely. There is always a very large, and in theory infinite, number of structural solutions consistent with any observed anomaly, although in practice the quantity of possible structures may often be reduced to more manageable proportions by a combination of common sense, experience of comparable environments, and complementary geological, geophysical or geochemical data. In the end, however, the decision about the 'most reasonable' structure model is likely to depend as much on the quality and amount of the support data as on the gravity anomaly itself.

Disagreements over the interpretation of gravity are therefore common, especially where associated non-gravity data are poor; and this seems to be the situation in the Galapagos Islands. Last year, Case *et al.* (*Science*, **181**, 1040; 1973) reported that over the islands there is a residual negative anomaly of at least 80 mgal superimposed on a broader positive anomaly of unknown amplitude and extent; and they interpreted this in the light of geological evidence in terms of a low density subsurface region related to a hot spot or mantle plume.

But those earth scientists (and there are many) who do not believe in plumes may breathe again, for Watts and Cochran (*Science*, **184**, 808; 1974) have now come up with a model involving simply downwarping of the lithosphere under the weight of the islands—an alternative actually considered and not entirely discounted by Case and his colleagues themselves. Watts and Cochran do not claim their structure is necessarily the right one, nor that a plume does not necessarily underlie the Galapagos; their main point is to re-emphasise the inherent ambiguity of gravity data. Everybody agrees that the matter will not be resolved until other, perferably seismic, data become available.

Hedgerow removal and bird life

from Peter D. Moore
Plant Ecology Correspondent

IN 1962 it was estimated that there were 616,000 miles of hedges in Great Britain (Locke, *Q. Jl For.*, **56**, 137; 1962). This was calculated by Moore, Hooper and Davis (*J. appl. Ecol.*, **4**, 201; 1967) to represent an area of 448,000 acres, which was more than twice the area of the British National Nature Reserves of that time. It was further suggested in these reports that the number of breeding bird species in agricultural land was about twice as great in regions with hedges than in areas where hedges had been removed. Very naturally these authors regarded the extensive clearance of hedges in Britain as one of the principal detrimental events in land management in recent years and it had lead in particular to a reduction in the quantity and diversity of bird life in rural districts.

These findings have been generally accepted, but Murton and Westwood (*Br. Birds*, **67**, 41; 1974) now question their validity. These authors claim that the overall diversity of birds in a 200-acre sample area of agricultural land in Cambridgeshire has changed little, and may even have increased, since it was last censured in 1960–61. This is despite a reduction in hedgerows to one third of their former extent and the reclamation of half of the area then considered 'rough and waste'. These results are bound to cause confusion among conservationists.

One should first ask what is meant by diversity in this context. Murton and Westwood use an index of diversity devised by Fisher, Corbett and Williams (*J. anim. Ecol.*, **12**, 42; 1943) which is based on the assumption that the frequency distribution of species ranked according to the number of individuals by which they are represented, follows a logarithmic series. Although this frequency relationship has often been demonstrated in plant and animal communities, such theoretical indices can be misleading; an empirically derived diversity measure would have been preferable (see Hurlbert, *Ecology*, **52**, 577; 1971).

Whatever the relative merits of diversity indices, one is still faced with the fact that during the ten year period, the total number of species recorded in summer rose from 63 to 66 (although 19 of these species had decreased in numerical abundance) and in winter fell from 65 to 59; in effect there was little change in the total number of species recorded. Murton and Westwood account for this by considering the hedgerow to be a suboptimal habitat for most species which breed in them. Hedgerow removal therefore results in either a retreat of the species to optimal sites (such as woodland) or a modification in the bird's breeding behaviour (blackbirds may nest among the stumps of the cleared hedgerow and along ditch banks). Less adaptable species such as the song thrush may decrease, but are often replaced by other species such as the reed bunting.

These explanations are very acceptable but they do suggest that the area sampled is not typical of regions in which hedgerow clearance has been practised. It differs in the retention of woodland fragments, hedgerow stumps and ditches, all of which serve to maintain diversity. Their conclusions cannot, therefore, be construed as general principles relating to the widespread effects of hedgerow removal.

Lethal mutants in *Drosophila* development

from Benjamin Lewin
Molecular Genetics Correspondent

THE imaginal disks of *Drosophila* provide one of the most promising systems for the genetic analyses of development and the recent isolation of many lethal mutants in disk development is therefore an important step towards defining the components of the system. The disks are larval tissues which subsequently give rise to many of the adult tissues; they include wing, leg, antenna and eye disks. Each disk is thus determined to produce a particular adult structure, the differentiation of which is triggered on metamorphosis. The disks provide an interesting experimental system, for passage of disks through the abdomens of adult flies allows indefinite continued growth, without loss of the determined state (which can be tested by injected tissue into larvae and identifying the adult tissues formed from it after metamorphosis). Transdetermination occasionally takes place, when the state of determination of tissue changes from one disk type to another; and homoeotic mutants exist in which certain disks give rise to adult structures usually formed from other disks.

The independence of the programmes for larval and adult development in *Drosophila* is emphasised by the observation that mutants which prevent disk development may be lethal to the adult but need not affect the larval stage at all. The characterisation of lethal mutants which affect all the disks is reported by Shearn and Garen in the April issue of the *Proceedings of the National Academy of Sciences* (**71**, 1393–1397; 1974). The mutants fall into two classes: *diskless* mutants form no imaginal disks; whereas *small disk* mutants form some or all of the disks, but whichever are present are small, misshapen and cannot differentiate into adult structures.

Mutants were isolated by screening for lethals dying in late development after treatment with chemical mutagens. The 23 *diskless* and 34 *small disk* mutants fall into 52 complementation groups; 48 groups contained one

mutant, three contained two mutants each and one contained three *small disk* mutants. One of the groups with two mutants comprised two *diskless* phenotypes, one included two *small disk* types, and the third represented one of each phenotype.

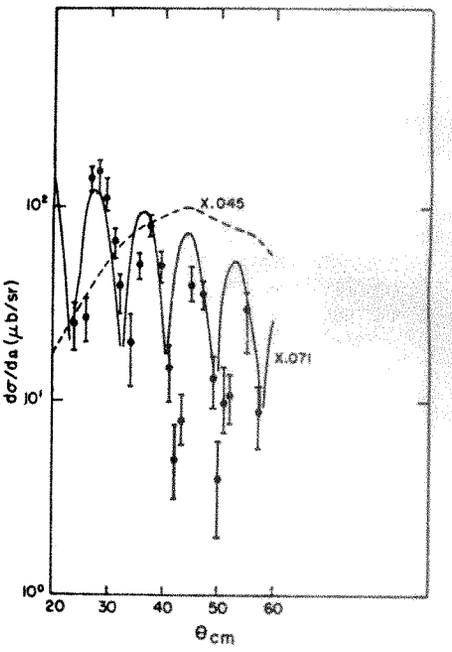
Two types of developmental deficiency might influence all the disks: some feature of the larval environment essential for development of all disks might be lacking; or some autonomous function common to all disks might be defective. The first model can be tested by injecting disks of normal larvae into the *diskless* and *small disk* larvae to see whether normal growth is possible; the second model can be tested by injecting suspensions of cells from early embryos of the mutants into normal larval hosts to see whether adult structures derived from disks are present after metamorphosis.

Injection of cells from *diskless* early embryos into wild type hosts did not lead to development of any adult structures when the *diskless* mutant was homozygous; such structures can, of course, be formed by cells from *diskless*/+heterozygous embryos. Quite different results were obtained when cells were taken from *small disk* mutants—these could provide the complete range of adult structures specified by all disk types (whether the mutation was in homozygous or heterozygous state).

When this experiment was carried out in reverse, wild type disks injected into *diskless* mutant larvae appeared to grow normally; although this experiment cannot, of course, be taken to the desirable conclusion of following the differentiation of wild type disks in *diskless* larvae, when the injected disks were retrieved before larval death and then reimplanted into normal larvae, they developed normally during metamorphosis. But in contrast, wild type disks cannot grow in one *small disk* host, although they do develop normally on subsequent injection into a normal larva; and in another *small disk* mutant host, some growth (although apparently abnormal) takes place, and the disk then loses its ability to develop normally upon subsequent implantation in a normal host.

Small disk mutants therefore seem to possess competent imaginal disks at an early stage of embryogenesis, but the disks subsequently fail to develop normally because the environment is in some way defective. The developmental potential of the disks seems to be irretrievably lost by the third instar stage which immediately precedes metamorphosis. (But the phenotype of the *small disk* class seems to cover some heterogeneity; for example, the *small disk* and one *diskless* mutant behaves as a *diskless* host when wild type disks are injected into its larvae.) The *diskless* mutants seem to represent a different type of defect; some function involved in the (autonomous) development of all disks must be mutant.

The selective system used to isolate these mutants applied only to the third chromosome; by applying a Poission distribution to the number of complementation groups with one and two members, Shearn and Garen inferred that there may be almost 400 further (at present unidentified) groups on this chromosome. This would imply that the genome of *Drosophila in toto* may possess about 1,000 complementation groups implicated in disk development —about one fifth of the total estimated number of complementation groups. Although the sample of isolated mutants is not large enough to make this an accurate estimate, it clearly implies that a large proportion of the genes of *Drosophila* may be concerned with the development of imaginal disks, an important conclusion. Isolation and mapping of further mutants may therefore be profitable.



Most important, of course, will be experiments to implicate particular genes in defined pathways of disk development. And in addition to the many autonomous functions common to all disks, revealed by the *diskless* mutant class, there must be gene functions specific for each state of determination. Mutants defective in development of an individual disk type would therefore be useful, although difficult to obtain. And increasing success with genetic analysis must in turn emphasise the need for biochemical analyses of the disk system, a problem which at present looks difficult to overcome.

Transfer of excited alpha particles

from Peter E. Hodgson
Nuclear Theory Correspondent

MANY studies are now being made of the reactions in which an α particle is transferred from one nucleus to another, and these are providing important new information on nuclear structure. Some recent work by Charlton and Robson (*Phys. Rev. Lett.*, **32**, 946; 1974) has now provided evidence to suggest that the α particles can sometimes be transferred in an excited state and not only in its ground state as was previously assumed.

They analysed the differential cross section for the ^{32}S (^{16}O, ^{12}C) ^{36}Ar reaction obtained by Braun-Munzinger and colleagues in Heidelberg (*Phys. Rev. Lett.*, **31**, 1423; 1973). Some of these results are shown in the figure and it is notable that the cross section has a strongly oscillatory structure.

Differential cross section for the reaction ^{32}S (^{16}O, ^{12}C) ^{36}Ar at 30 MeV to the ground state of the residual nucleus compared with distorted wave calculations assuming the transferred α particle to be in its ground (– – –) and in its excited 2^+ state at 28.5 MeV (———). In – – –, $V=100$; $W=30$, $r^r_0=1.22$; $r^i_0=1.25$; $a^r=0.5$; $a^i=0.4$. In ———, $L_c=18$; △ $L=0.8$. The numbers on the curves are the spectroscopic factors obtained by normalising the calculated curves to the experimental data.

The cross sections for α-transfer reactions between nuclei can now be calculated quite well by the finite-range distorted-wave theory, provided the recoil effects are taken into account. Such calculations were made and gave a rather structureless distribution with a broad peak at about 45° as shown by the dashed line in the figure. This is in accord with semi classical calculations, which give a bell-shaped curve centred at an angle corresponding to the scattering of a particle whose orbit just grazes the nuclear surface. This behaviour is completely different from that found experimentally.

Further calculations were then made taking into account the possibility that the α particle is transferred in an excited state. The 0^+ level at 20.2 MeV and the 2^+ level at 28.5 MeV were considered, as these satisfy the required parity and isospin selection rules. Estimates using harmonic oscillator wavefunctions indicated that reactions with the α particle in the 2^+ state are about a hundred times stronger than those with the 0^+ state, so only the former was considered.

The excited states of the α particle were assumed to be made up of pairs of like nucleons with the smallest possible internal motion, and the quantum numbers for the relative motions of the pairs give the required total spin.

In the dissociation $^{36}Ar \rightarrow {}^{32}S + \alpha^*$, the four valence nucleons were assumed to be in the $0d_{3/2}$ orbit and the probability of the α particle being in an excited state was estimated using both the stretch scheme and the simple pairing model. Both calculations indicated that the α particle is more likely to be found in an excited state. The corresponding spectroscopic factors indicate that the transfer of an α particle in its 2^+ state is about five times more likely than the transfer in its ground state for the reaction considered.

The distorted-wave calculations for excited α-particle transfer were carried out in the standard way and used absorbing potentials depending on the orbital angular momentum in the way required by analyses of the elastic scattering of heavy ions by nuclei. The results are shown by the full line in the figure, and agree very well with the experimental data. Similar results are found for the corresponding reaction to the lowest 2^+ state of ^{36}Ar.

This is clearly a significant result that will stimulate many more investigations. In principle, the ground and all the excited states of the α particle should be added coherently to give the distorted-wave amplitude. More detailed analyses of similar reactions on other nuclei should provide further evidence of excited α transfer but the results of Charlton and Robson provide good evidence that such processes can take place.

Synchrotron radiation users meet

from G. V. Marr

THE electromagnetic radiation emitted from high energy electron synchrotrons, as a consequence of radially accelerating the electrons, is now well established as a means of studying the interaction of ultraviolet and X radiation with matter in its various forms. The first international symposium for synchrotron radiation users was held at the Daresbury Laboratory in January 1973 (see *Nature phys. Sci.*, **242**, 1; 1973) following the move of United Kingdom users from the Glasgow synchrotron to NINA in 1972. During the past year, demand for synchrotron radiation has increased and the conference held at the University of Reading from April 1 to 2, under the auspices of the spectroscopy group of the Institute of Physics, provided a means whereby the UK users could discuss the relevance of this source. The contributions covered present and future synchrotron radiation sources, applications to atomic, molecular, chemical and solid state physics, biological studies, chemistry, X-ray optics and radiometry. The conference concluded with an open meeting with Science Research Council representatives to discuss the SRC paper "A Plan for Future Research with Synchrotron Radiation based on a Dedicated Storage Ring".

The main energy loss from the electron synchrotron is in the form of electromagnetic radiation whose spectrum extends continuously from the infrared to the X-ray region. It provides an intense source of high energy photons, predominantly polarised in the plane of the electron orbit and, because of the bunching of the electrons, pulsed at the accelerator radio frequencies. The radiation is emitted under good vacuum conditions and with divergences from the orbit plane comparable with a laser beam (see *Endeavour*, **33** (119) 55–66, May 1974).

Facts and figures for existing synchrotron sources were provided by I. H. Munro (Daresbury and University of Manchester) who outlined criteria for the ideal synchrotron source based on design work for the dedicated electron storage ring now under consideration by the Science Research Council. Progress with existing synchrotrons in atomic and molecular physics was introduced by K. Codling (University of Reading). In addition to energy level analysis, accurate absolute cross-sectional data are being provided on photoionisation processes and new experiments which allow photo-electron analysis to be carried out with respect to the E vector of the ionising radiation are now in progress. Continuous variation of the photon energy is providing data which will extend knowledge of configuration interaction, molecular orbitals and vibronic coupling; a point which was taken up by S. Leach (University of Paris, Orsay) in his review of applications in chemical physics where excited state relaxation processes in molecules and solids can benefit from lifetime studies using the modulated nature of the ultraviolet radiation of the synchrotron.
